Self-efficacy and future anxiety among students of nursing and education colleges of Helwan University

Samah Rabei¹*, Sorayia Ramadan² and Nahla Abdallah¹

Abstract

Background: Self-efficacy and future anxiety affect students' performance. A relation between both is suggested and needs to be investigated. The aim of this study is designed to assess self-efficacy, future anxiety among Helwan University students, and the relation between them.

Results: Ten percent of colleges’ students were subjected to self-efficacy scale and future anxiety scales. Future anxiety is significantly related to self-efficacy. Self-efficacy is significantly higher in the college of nursing. There is a significant increase in self-efficacy in the 1st grade, while there is a significant increase in future anxiety in the 4th grade.

Conclusion: There is a negative significant correlation between age and self-efficacy, while there is a positive significant correlation between age and future anxiety.

Background

Goal realization is composed of four processes: self-observation, self-evaluation, self-reaction, and self-efficacy [1]. Self-efficacy can be defined as individuals’ beliefs about their capabilities to produce designated levels of performance that influence over events affecting their lives. The beliefs determine how people feel, think, motivate themselves, and behave, which are added to the production of diverse effects through cognitive, motivation, and affective processes [2]. According to Tirana 2013, the four sources of information that individual employs to judge their efficacy are performance outcomes (performance accomplishments), vicarious experiences, verbal persuasion, and physiological feedback (emotional arousal). These components help individuals determine if they believe they have the capability to accomplish specific tasks [3].

The root meaning of the word anxiety is “to vex or trouble”; in either the presence or absence of psychological stress, anxiety can create feelings of fear, worry, uneasiness, and dread [4]. Anxiety can be defined as a psychological and physiological state characterized by physical, emotional, cognitive, and behavioral components. It is considered to be a normal response to stress. It may help an individual to cope with the demands of life, but in excess, it may be considered as an anxiety disorder [5]. Future anxiety can be defined as a state of apprehension, uncertainty, fear, worry, and concern of unfavorable changes in a more remote personal future. In an extreme case, this would be a threat (panic) that something really catastrophic may happen to a person [6]. People who suffer from future anxiety have some characteristics as decremented efficiency in experimental tasks [7]. Negative effects of future anxiety are as follows: on the cognitive level, El-Meshekhy [8] refers that future anxiety may lead to [1] an impairment of the subjective expectancy of positive outcomes of one’s own actions, so lessening the probability of success and [2] an attention concentration on the present time and events; or escapism into the known past, both mechanisms limiting the temporal space of an individual. On the
behavioral level, Cassady [9] refers that future anxiety may lead to [1] a passive waiting of what can occur [2]; withdrawal from risky, open, and constructive activities [3]; keeping to routine ways and tested methods of dealing with situations encountered in life [4]; undertaking preventive activities in order to preserve the status quo rather than taking risks to increase present opportunities [5]; using different regressive-type defense mechanisms such as accusation, rationalization, or repression, in order to reduce the negative state; and [6] the use of social relationships to help secure one’s own future.

A negative correlation is found between social anxiety and self-efficacy by Al Rauwaili et al. [10]. Self-efficacy promotes resilience unlike anxiety which impairs resilience that affects well-being as proven by Wylds [11].

Methods
A) Setting: in the College of Nursing and College of Education, Helwan University
B) Subject: 10% of the total number of university colleges chosen according to random selection in the College of Nursing and College of Education (represent practical and theoretical colleges).
C) Timetable: between June and December 2016
D) Tools for data collection:

- A structured questionnaire for socio-demographic variables
- Self-efficacy scale [12]: 32 statements in 4 main items (performance accomplishment, vicarious experiences, persuasion, emotional arousal). These scores were converted into a percent score by multiplying the score by 100 and dividing it by maximum possible score
- Future anxiety scale [13]: 40 statements in 4 main items (fear of future problems, pessimism, future worry thinking, death anxiety). These scores were converted into a percent score by multiplying the score by 100 and dividing it by maximum possible score

E) Statistical analysis was done using SPSS version 20

| Table 1 Demographic data of the studied group |
|-----------------------------------------------|
| Total “n = 481”                                |
| Age                                           |
| < 20                                          | 289 | 60.1 |
| > 20                                          | 192 | 39.9 |
| Grade                                         |
| 1st year                                      | 289 | 60.1 |
| 4th year                                      | 192 | 39.9 |
| College                                       |
| Education                                     | 411 | 87.2 |
| Nursing                                       | 70  | 12.8 |

| Table 3 Future anxiety among students        |
|-----------------------------------------------|
| Future anxiety scale                         |
| No. %                                        |
| The fear of future problems                  |
| Strongly disagree                            | 3   | 6.6 |
| Disagree                                     | 103 | 21.4|
| Neutral                                      | 258 | 53.6|
| Agree                                        | 111 | 23.1|
| Strongly agree                               | 6   | 1.2 |
| Pessimism about the future                   |
| Strongly disagree                            | 1   | 2.2 |
| Disagree                                     | 70  | 14.6|
| Neutral                                      | 292 | 60.7|
| Agree                                        | 116 | 24.1|
| Strongly agree                               | 2   | 4.4 |
| Worry thinking about the future              |
| Strongly disagree                            | 35  | 7.3 |
| Neutral                                      | 349 | 72.6|
| Agree                                        | 93  | 19.3|
| Strongly agree                               | 4   | 8.8 |
| Death anxiety                                |
| Strongly disagree                            | 4   | 8.8 |
| Disagree                                     | 70  | 14.6|
| Neutral                                      | 272 | 56.5|
| Agree                                        | 125 | 26.0|
| Strongly agree                               | 10  | 2.1 |
| Total                                        | 481 | 100.0|
Ethical considerations
Informed written consent was taken from parents before participation. The aim and procedures of the study were explained to them. There was no moral or financial pressure laid on them to participate. Confidentiality was assured. The results of the study are planned to a scientific publication that serves and improves policies and plans affecting their quality of life.

Results
Table 1 shows that 60% of the study sample participants are below the age of 20 and in the first year grade. Also, 87.2% of the study sample participants are in the College of Education.

Table 2 shows that almost 60% of study sample participants are (Much Sure) of their self-efficacy performance accomplishment and vicarious experiences, persuasion, and emotional arousal.

Table 3 shows that more than half of the study sample participants are (neutral) as regards their future anxiety: fear of future problems, 60% are (neutral) as regards pessimism, 72% are (neutral) as regards future worry thinking, and 56% are (neutral) as regards fear of death.

In Table 4, by comparing future anxiety levels as regards self-efficacy levels using chi-square test; it is clear that all participants with high self-efficacy (no. = 3, 100%) has low anxiety level; participants with moderate self-efficacy: 27% has low anxiety and 71.4% has low anxiety.

| Future anxiety scale category | Self-efficacy scale category | Total |
|------------------------------|-----------------------------|-------|
|                              | Low | Mild | Moderate | High |
| Low                          | 0   | 10   | 17       | 3    | 100.0 | 30 |
| Mild                         | 26  | 90   | 45       | 0    | 0.0   | 161 |
| Moderate                     | 133 | 54.5 | 1        | 0    | 0.0   | 254 |
| High                         | 36  | 71.4 | 0        | 0    | 0.0   | 36  |
| Total                        | 195 | 220  | 63       | 3    |       |     |
| $X^2$                        | 26.85 |
| $p$                          | 0.001* |

These findings have high statistical significance as per chi-square test ($p$ value + 0.001)

In Table 5, by comparing college type as regards both future anxiety and self-efficacy crude scores using Student $t$ test: it is clear that the mean score of self-efficacy and future anxiety of students in the College of Education is lower than students in the College of Nursing.

In Table 6, by comparing 1st and 4th year as regards both future anxiety and self-efficacy crude scores using Student $t$ test: it is clear that the mean score of self-efficacy and future anxiety of students in the 4th year is lower than students in the 1st year.

These findings have high statistical significance as per Student’s $t$ test ($p$ value + 0.001)

In Table 7, there is a strong inverse correlation between future anxiety and self-efficacy

| Table 4 Comparing future anxiety levels as regards self-efficacy levels |
|---------------------------------------------------------------|
| Future anxiety scale category | Self-efficacy scale category | Total |
|------------------------------|-----------------------------|-------|
|                              | Low | Mild | Moderate | High |
| Low                          | 0   | 10   | 17       | 3    | 100.0 | 30 |
| Mild                         | 26  | 90   | 45       | 0    | 0.0   | 161 |
| Moderate                     | 133 | 54.5 | 1        | 0    | 0.0   | 254 |
| High                         | 36  | 71.4 | 0        | 0    | 0.0   | 36  |
| Total                        | 195 | 220  | 63       | 3    |       |     |
| $X^2$                        | 26.85 |
| $p$                          | 0.001* |

| $p$                      | 0.0001*   | 0.069   |        |

Discussion
The present study reveals that there is a negative correlation between self-efficacy and future anxiety. It may due to the challenges that face the university students that include specialty selection, friends’ choice, independence desire, exam stressors, fear of failure, residence in the University City and demands of the work field; all these challenges lead to variable levels of anxiety that often increase accompanied with a decrease in self-efficacy when the student realized disability to face these challenges. This finding is supported by the findings of Sediek [14], whose study on 249 university students at Helwan University revealed that there is a negative relation between self-efficacy and future anxiety. This also agrees with Wylds [11] and Rauwaili [10].

The present study reveals that there is a negative significant correlation between the age and grade of students and self-efficacy; it may be due to the educational systems in Egypt play role in loss the student self-confidence through the curriculum, and thus, the ability to reach the goal while there is a positive significant correlation between age of students and future anxiety. It may be due to the challenges, fear of the future, and pessimistic view increase with the age. The present study reveals that there was a significant increase in self-efficacy.
students suffer a decline in the level of optimism that leading to increase the symptoms of future anxiety. On a different line, Gaber [4] study, done on a sample of 81 students from Faculty of Education and Faculty of Engineering at Najran University, revealed that there is a significant statistical difference between the theoretical and scientific disciplines’ students regarding future anxiety in the direction of theoretical disciplines’ students. A third line is the research of Al-Momani & Naeem [15], done on 439 college students in Al Jalil Region, revealed that there is no statistically significant difference regarding future anxiety among his sample. Further research is required to investigate these different findings and analyze the environmental role in these variations.

**Conclusion**

Further studies as regards the relationship between future anxiety and self-efficacy are required. Designing programs for developing the concept of self-efficacy on the basis of learning by modeling and reinforcing and putting therapeutic programs for future anxiety based on cognitive and emotional therapy is essential. Putting educational programs through the Ministry of Education to enhance self-efficacy and enriching the curriculum in all grades, especially university subjects contribute to raising levels of professional and academic ambition and help to reduce the level of future anxiety, can help. Organizing conferences through the Ministry of Higher Education to identify the social and economic problems of the youth and adopting set up debates, lectures, and opening chat channels with youth to create public awareness, is no luxury. Policy makers should be addressed to put future plans to identify the numbers admitted to the university according to the need of the Ministry of Higher Education to put an end to the problem of unemployment.
