Abstract

We propose a generalized Zee-Babu model with a global $U(1)$ B-L symmetry, in which we classify the model in terms of the number of the hypercharge $N/2$ of the isospin doublet exotic charged fermions. Corresponding to each of the number of $N$, we need to introduce some multiply charged bosons in order to make the exotic fields decay into the standard model fields. We also discuss the muon anomalous magnetic moment and the diphoton excess depending on $N$, and we show what kind of models are in favor of these phenomenologies.

I. INTRODUCTION

The recent measurements reported by ATLAS and CMS experiments implies that a new particle ($\Phi_{\text{New}}$) might exist at around 750 GeV by the diphoton invariant mass spectrum from the run-II data in 13 TeV [1, 2]. And a typical interpretation is known as

$$\mu_{\text{ATLAS}} = \sigma(2p \rightarrow \Phi_{\text{New}}) \times BR(\Phi_{\text{New}} \rightarrow 2\gamma) = (6.2^{+2.4}_{-2.0}) \text{ fb}, \quad (I.1)$$

$$\mu_{\text{CMS}} = \sigma(2p \rightarrow \Phi_{\text{New}}) \times BR(\Phi_{\text{New}} \rightarrow 2\gamma) = (5.6 \pm 2.4) \text{ fb}. \quad (I.2)$$

Furthermore the ATLAS experiment group [1] announced $\Gamma_{\Phi_{\text{New}}} = 45$ GeV, which is the best fit value of the total decay width of $\Phi_{\text{New}}$, while the CMS experiment group [2] indicated a rather smaller decay width. It might suggest that $\Phi_{\text{New}}$ be a scalar (or pseudoscalar) and additional new fields with nonzero electric charges are in favor of being introduced, since sizable branching fraction for $\Phi_{\text{New}} \rightarrow \gamma\gamma$ requires $\Phi_{\text{New}}$ strongly interacts with such charged fields. In order to provide reasonable explanations (or interpretations), a vast of paper along this line of issue has been recently arisen in Ref. [3–181].

Zee-Babu type [182] of radiative seesaw models could provide one of the economical scenarios to include such new exotic fields with nonzero electric charges (bosons or fermions) that are naturally introduced in order not only to explain the diphoton excess but also to explain the tiny neutrino masses. Also the model can easily be extended to the multi-charged bosons and fermions.

In our paper, we propose a generalized Zee-Babu model with a global $U(1)$ B-L symmetry, in which neutrino masses are induced at the two loop level. Here we introduce vector like isospin doublet fermions with general $N/2$ hypercharges that can explain the discrepancy of the muon anomalous magnetic moment to the standard model (SM) sizably. Corresponding to each of the number of $N$, we need to introduce some multiply charged bosons in order to make the exotic fields decay into the standard model fields. Diphoton excess is explained by introducing several charged bosons, depending on the number of $N$. Here we classify the model according to the number of $N$, and we discuss what kind of models are in favor of explaining the sizable diphoton resonance as well as the muon anomalous magnetic moment.

In Sec. II, we show our model, including neutrino sector, and muon anomalous magnetic moment. In Sec. III, we discuss the decay processes of exotic fields. In Sec. IV, we discuss the diphoton excess. We conclude and discuss in Sec. V.
II. MODEL SETUP AND ANALYSIS

In this section, we explain our model with a global $U(1)_{B-L}$ symmetry. The particle contents and their charges are shown in Tab. I. As for the fermions, we add some vector-like exotic isospin doublet charged fermions $L'$ with $-N/2$ hypercharge and isospin singlet fermions $E'$ with $-N/2$ hypercharge, where $N(=1,3,5,...)$ is generally an arbitrary odd number. As for the scalars, we introduce a $\pm M(\neq 0)$ electric charged scalar $h^{\pm M}$, and a $\pm 2M$ charged scalar $k^{\pm 2M}$ with different $U(1)_{B-L}$ quantum numbers, and a neutral scalar $\varphi$ in addition to the SM. Notice here that the electric charge to the fields with the $-N/2$ hypercharge, i.e., $L'$, is given as

$$Q_{L'} = \left[\frac{1}{2}, -\frac{1}{2}\right] + \left[\frac{-N}{2}, -\frac{N}{2}\right] = \left[\frac{1-N}{2}, -\frac{1+N}{2}\right] \equiv [-M, -M-1]^T. \quad (II.1)$$

Thus we define $L'$ as

$$L' \equiv [\psi^{-M}, \psi^{-M-1}]^T. \quad (II.2)$$

We assume that only the Higgs doublet $\Phi$ and $\varphi$ have vacuum expectation values (VEVs), which are respectively symbolized by $v/\sqrt{2}$ and $v'/\sqrt{2}$.

\hline
$U(1)_Y$ & $-1/2$ & $-1$ & $-N/2$ & $-M$ & $1/2$ & $+M$ & $+2M$ & 0 \\
\hline
$U(1)_{B-L}$ & $-1$ & $-1$ & $-3$ & $-3$ & 0 & 2 & 6 & $-2$ \\
\hline
\end{tabular}
\end{center}
\caption{Contents of fermion and scalar fields and their charge assignments under $SU(2)_L \times U(1)_Y \times U(1)_{B-L}$, where $M$ is defined by $M = (1 + N)/2$ with $N(=1,3,5,...)$ is the odd number.}
\end{table}
The relevant Lagrangian and Higgs potential under these symmetries are given by

\[ -\mathcal{L}_Y \supset y_L L^c_R \Phi e_R + f L_L L_R h^+ + g_{L/R} E^c_{L/R} E_{L/R} k^{+2M} + h_{L/R} L^c_R \Phi E_{L/R} + M_L L^c_R + M_E E_L E_R + \text{c.c.}, \]  

\[ V = m_\phi^2 |\phi|^2 + m_h^2 |h^+|^2 + m_k^2 |k^{+2M}|^2 + m_{\phi h}^2 (k^{+2M} h^- M k^- M \varphi + \text{c.c.}) + \lambda_\phi |\phi|^4 + \lambda_h |h^+|^4 + \lambda_k |k^{+2M}|^4 + \lambda_{\phi h} |\varphi|^2 |\phi|^2 + \lambda_{h k} |h^+|^2 |k^{+2M}|^2 + \lambda_{h \phi} |h^+|^2 |k^{+2M}|^2, \]  

where \( \Phi \equiv i \sigma_2 \Phi^* \), the flavor indices are abbreviated and all the couplings are assumed to be positive and real for brevity. After the global \( U(1)_{B-L} \) spontaneous breaking by \( \langle \varphi \rangle = v' / \sqrt{2} \), we obtain the trilinear term \( \lambda \omega \sqrt{2} k^{+2M} h^- M h^- M \) that plays an role in generating the neutrino masses at the two loop level. The first term of \( \mathcal{L}_Y \) generates the SM charged-lepton masses \( m_\ell \equiv y_L v_1 / \sqrt{2} \) after the spontaneous breaking of electroweak symmetry by \( \langle \Phi \rangle = v / \sqrt{2} \).

The isospin doublet scalar field is parameterized as \( \Phi = [w^+, \frac{w^+ + h^- + i z}{\sqrt{2}}] \) where \( v \approx 246 \text{ GeV} \) is VEV of the Higgs doublet, and the component of \( w^\pm \) and \( z \) are respectively absorbed by the longitudinal component of \( W \) and \( Z \) boson. The isospin singlet scalar field can be parameterized by \( \varphi = \frac{v^+ + h^-}{\sqrt{2}} e^{-iG / v'} \). Then we consider the mixing of the CP-even Higgses, where the mass eigenstates are given by

\[ \left( \begin{array}{c} h_1 \\ h_2 \end{array} \right) = \left( \begin{array}{cc} \cos \alpha & -\sin \alpha \\ \sin \alpha & \cos \alpha \end{array} \right) \left( \begin{array}{c} H \\ h \end{array} \right). \]  

Here \( h \) and \( H \) denote SM Higgs and heavier CP-even Higgs respectively.

**Exotic Charged Fermion mass matrix:** The exotic charged fermion mass matrix with \( \pm M \) electric charges is given by

\[ -\mathcal{L}_{\text{mass}} = \begin{pmatrix} E^- & \psi^- \end{pmatrix} \begin{pmatrix} M_E & m' \\ m' & M_L \end{pmatrix} \begin{pmatrix} E^- \\ \psi^- \end{pmatrix} + \text{h.c.} = \begin{pmatrix} E_1^- & E_2^- \end{pmatrix} \begin{pmatrix} M_{E^1} & 0 \\ 0 & M_{E^2} \end{pmatrix} \begin{pmatrix} E_1^- \\ E_2^- \end{pmatrix} + \text{h.c.}, \]  

where we assume to be \( m' = \frac{v}{\sqrt{2}} h_L = \frac{v}{\sqrt{2}} h_R \) and \( h^T = h = h_L = h_R \) for simplicity. The mass eigenstates \( E^1 \) and \( E^2 \) are defined by the bi-unitary transformation:

\[ \begin{pmatrix} E^- \\ \psi^- \end{pmatrix} = \begin{pmatrix} c_{\theta_E} & -s_{\theta_E} \\ s_{\theta_E} & c_{\theta_E} \end{pmatrix} \begin{pmatrix} E_1^- \\ E_2^- \end{pmatrix}, \]  

where \( \theta_E \) is the mixing angle.
where \( s_{\theta_E} \equiv \sin \theta_E \) and \( c_{\theta_E} \equiv \cos \theta_E \). The mass eigenvalues and the mixing angles \( \theta_E \) are respectively given by

\[
M_{E1,2} = \frac{1}{2} \left( M_E + M_L + \sqrt{(M_E - M_L)^2 + 4m'^2} \right), \quad \tan 2\theta = \frac{2m'}{M_E - M_L}, \quad (\text{II.8})
\]

where we define \( M_{E1} < M_{E2} \), and the mass of the \( \pm (M+1) \) electric charged fermion \( \psi_{\pm(M+1)} \) is given by \( M_L \).

**Neutrino mass matrix:**

The leading contribution to the active neutrino masses \( m_\nu \) is given at two-loop level as shown in Figure 1 and its formula \[184\] is given as follows:

\[
(m_\nu)_{ij} = -\frac{\sqrt{2}\lambda_0 v' (\sin 2\theta)^2 f_{i\alpha} g^*_{\alpha\beta} f_{j\beta}}{4(4\pi)^4} \Pi_2, \quad (\text{II.9})
\]

\[
\Pi_2 \equiv \int \frac{dx dy dz}{z^2 - z} \delta(a + y + z - 1) \int d\alpha d\beta d\gamma \delta(\alpha + \beta + \gamma - 1)
\]

\[
\times \left[ z \ln \frac{\Delta(E_{1\alpha}, E_{2\beta})}{\Delta(E_{1\alpha}, E_{1\beta})} + z \ln \frac{\Delta(E_{2\alpha}, E_{1\beta})}{\Delta(E_{2\alpha}, E_{2\beta})} \right] + M_{E_{1\alpha}} \left[ \frac{M_{E_{1\beta}}}{\Delta(E_{1\alpha}, E_{1\beta})} - \frac{M_{E_{2\beta}}}{\Delta(E_{2\alpha}, E_{2\beta})} \right] + M_{E_{2\alpha}} \left[ \frac{M_{E_{2\beta}}}{\Delta(E_{2\alpha}, E_{2\beta})} - \frac{M_{E_{1\beta}}}{\Delta(E_{2\alpha}, E_{1\beta})} \right], \quad (\text{II.10})
\]

\[
\Delta(x, y) \equiv -\alpha \frac{xM^2_E + ym^2_{h^\pm M} + zm^2_{{k^\pm 2M}}}{z^2 - z} + \beta M^2_y + \gamma m^2_{h^\pm M}, \quad (\text{II.11})
\]

where \( m_\nu \) should be \( 0.001 \text{ eV} \lesssim m_\nu \lesssim 0.1 \text{ eV} \) from the neutrino oscillation data \[183\]. Reminding the original Zee-Babu model, the loop function \( \Pi_2 \) is the order 1. Once we fix
to be $\Pi_2 = 1$, we obtain the following parameter region to satisfy the neutrino mass scale as

$$71 \text{ eV} \lesssim \lambda_0 v'(\sin 2\theta)^2 f_{i\alpha} g_{\alpha\beta} f_{j\beta} \lesssim 7.1 \times 10^3 \text{ eV},$$

which can easily be realized due to a lot of free parameters.

**Muon anomalous magnetic moment:**

Brookhaven National Laboratory has announced a discrepancy between the experimental data and the prediction in the SM, and its difference, which is denoted by $\Delta a_\mu \equiv a_\mu^{\text{exp}} - a_\mu^{\text{SM}}$, is respectively given in Ref. [185] and Ref. [186] as

$$\Delta a_\mu = (29.0 \pm 9.0) \times 10^{-10}, \quad \Delta a_\mu = (33.5 \pm 8.2) \times 10^{-10}.$$  

The above results given in Eq. (II.13) correspond to $3.2\sigma$ and $4.1\sigma$ deviations, respectively.
Our formula of muon $g - 2$ is given by
\[
\Delta a_\mu \approx \frac{m_\mu^2 |f|^2}{(4\pi)^2} \left[ MF(\psi^{(M+1)}, h^{\pm M}) + (M + 1) F(h^{\pm M}, \psi^{(M+1)}) \right],
\]
(II.14)
\[
F(x, y) \approx \frac{2m_x^6 + 3m_x^4m_y^2 - 6m_x^2m_y^4 + m_y^6 + 6m_x^4m_y^2 \ln \left( \frac{m_x^2}{m_y^2} \right)}{12(m_x^2 - m_y^2)^4}.
\]
(II.15)

In fig. 2 we show the region plot in terms of $f$ and $M_{\psi^{(M+1)}}$ plane for $N = 5, 7, 9, 11, 13$ cases, where $m_{h^{\pm M}} = 380$ GeV and $N = 3$ does not have the allowed region. The yellow region satisfies the sizable muon anomalous magnetic moment $2.0 \times 10^{-9} \lesssim \Delta a_\mu \lesssim 4.0 \times 10^{-9}$. It suggests that the larger number of $N$ provides the larger value of anomalous magnetic moment.

Notice here that the lepton flavor violating (LFV) processes are always arisen in generating the muon anomalous magnetic moment. The most stringent constraint comes from the $\mu \rightarrow e\gamma$ process at the one-loop penguin diagram, and its upper bound of the branching ratio is given by $\text{BR}(\mu \rightarrow e\gamma) \lesssim 5.7 \times 10^{-13}$ [187] at the 95% confidential level. The theoretical formulation in our case is computed as
\[
\text{BR}(\mu \rightarrow e\gamma) \approx \frac{3\alpha_{em}|(ff^*)_{21}|^2}{32\pi G_F^2} \left[ MF(\psi^{(M+1)}, h^{\pm M}) + (M + 1) F(h^{\pm M}, \psi^{(M+1)}) \right]^2.
\]
(II.16)

To satisfy the constraint, the coupling $(ff^*)_{21}$ has to typically be $\mathcal{O}(10^{-4})$ under fixed masses; $m_{\psi^{\pm M}} = 100$ GeV, and $m_{h^{\pm M}} = 380$ GeV, where $M$ runs 1 to 6 as we will discuss in the next section. The result might conflict with the coupling to realize the sizable muon $g - 2$ in Fig. 2 however we can evade this problem by assuming the off-diagonal $2 - 1$ element of $ff^*$ to be zero. Even it is the case, the neutrino mixings are expected to be induced via the coupling of $g \equiv (gL/R)$. Hence we retain the consistency of the LFV constraints without conflict of the neutrino oscillation data and the muon anomalous magnetic moment, applying this assumption to the numerical analysis.

III. DECAY PROCESSES FOR THE EXOTIC FIELDS

Now that we have to consider the decay processes of the exotic fields. Regardless of the number $M$, $\psi^{-M-1}$ always decays into $\psi^{-M}$ and the charged gauged boson $W^-$. And $\psi^{-M}$ decays into $h^{-M}$ and active neutrinos, if the mass of $\psi^{-M}$ is greater than the mass of $h^{-M}$.
or $h^{-M}$ decays into $\psi^{-M}$ and active neutrinos, if the mass of $\psi^{-M}$ is less than the mass of $h^{-M}$. Moreover, $k^{-2M}$ can decays into $2h^{-M}$, if $2m_{h^\pm M} < m_{k^{\pm 2M}}$. In order to make the analysis simplify, we just assume to be $2m_{h^\pm M} < m_{k^{\pm 2M}}$. Therefore all we have to take care of the decay is how to make the $h^{\pm M}$ or $E^{\pm M}$ field decay into the SM fields, which quite depends on the number of $N$. Thus we classify the model in terms of the concrete number of $N$ below. Notice here that $N$ starts from three, since we assume to be $M \neq 0$.

A. $N=3$

This is equivalent to $M = 1$. In this case, we can add to write the term

$$-\mathcal{L}_{\text{new}} \approx y_e E \bar{E} e R \varphi + c.c.,$$

(III.1)

which suggests the mixing between the SM electric charged leptons and the exotic charged fermions. The mixing makes the neutrino mass matrix complicate, and $h^\pm$ cannot decay into the SM fields without any additional fields such as another doubly charged boson with $+2 \ U(1)_{B-L}$ charge, and there exist any allowed region to satisfy the muon anomalous magnetic moment in the last section. Thus we do not mention this case furthermore.

B. $N=5$

This is equivalent to $M = 2$. In this case, we can add to write the term

$$-\mathcal{L}_{\text{new}} \approx g' e_R^c e_R h^{++} + c.c.,$$

(III.2)

that suggest that $h^{--}$ can decay into the same di charged-leptons. Thus we do not need to add any additional fields, and decay processes are as follows:

$$h^{--} \rightarrow 2\ell^-. $$

(III.3)

Notice here that $g'$ can contribute to the negative contribution of the anomalous magnetic moment, but we can neglect this effect hereafter because this coupling can be take as a free free parameter.
C. **N=7**

This is equivalent to $M = 3$. In this case, introducing a new field $S^{\pm\pm}$ that is an isospin singlet doubly charged boson with $\pm 2 \, U(1)_{B-L}$ charge, we can add to write the term

$$-\mathcal{L}_{\text{new}} \approx g'e_R e_R S^{++} + y e E^{-3}_L e_R S^{--} + \text{c.c.},$$

(III.4)

where $S^{\pm\pm}$ plays as a role in generating the decaying processes for the exotic fields only. Then the decay processes are as follows:

$$h^{----} \rightarrow E^{----}(+\nu_L) \rightarrow S^{--}(+\ell^-) \rightarrow 2\ell^-.$$  

(III.5)

D. **N=9**

This is equivalent to $M = 4$. In this case, introducing a new field $S^{\pm\pm}$ that is an isospin singlet doubly charged boson with $\pm 2 \, U(1)_{B-L}$ charge, we can add to write the term

$$-\mathcal{L}_{\text{new}} \approx g'e_R e_R S^{++} + \lambda h^{++++} S^{--} S^{--} \varphi + \text{c.c.},$$

(III.6)

where $S^{\pm\pm}$ plays as a role in generating the decaying processes for the exotic fields only. Then the decay processes are as follows:

$$h^{-----} \rightarrow 2S^{--} \rightarrow 4\ell^-.$$  

(III.7)

E. **N=11**

This is equivalent to $M = 5$. In this case, introducing new fields $(S^\pm \, S^{\pm\pm} \, S^{\pm\pm\pm})$ that are respectively isospin singlet (singly, double, fourply) charged bosons with the common $\pm 2 \, U(1)_{B-L}$ charges, we can add to write the term

$$-\mathcal{L}_{\text{new}} \approx f'L^c_L L_S^+ + g'e_R e_R S^{++} + y e E^{-5}_L e_R S^{----}$$

$$+ \lambda S^{++++} + S^{--} S^{--} \varphi^* + \lambda'' h^{-----} S^{++} S^{++++} \varphi + \text{c.c.},$$

(III.8)

where additional fields play as a role in generating the decaying processes for the exotic fields only. Then the decay processes are as follows:

$$h^{-----} \rightarrow S^- + S^{-----} \rightarrow 2S^{--}(+\nu_L + \ell^-) \rightarrow 4\ell^-,$$

(III.9)

$$E^{-----} \rightarrow S^{----}(+\ell^-) \rightarrow 2S^{--} \rightarrow 4\ell^-.$$  

(III.10)
F. N=13

This is equivalent to $M = 6$. In this case, introducing new fields $(S^{\pm \pm} S^{\pm \pm \pm})$ that are respectively isospin singlet (double, fourply) charged bosons with the common $\pm 2$ $U(1)_{B-L}$ charges, we can add to write the term

$$-L_{\text{new}} \approx g' e_R^e R S^{++} + \lambda' S^{++++} + S^{--} S^{--} \varphi^* + \lambda'' h \varphi^{++++} S^{++++} \varphi + \text{c.c.},$$  \hspace{1cm} (III.11)

where additional fields play as a role in generating the decaying processes for the exotic fields only. Then the decay processes are as follows:

$$h^{------} \to S^{--} + S^{------} \to 6\ell^{-}. \hspace{1cm} (III.12)$$

IV. DIPHOTON EXCESS

We discuss the diphoton excess in case of $N = 5, 7, 9, 11, 13$ as discussed in the previous section where the candidate of 750 GeV scalar boson is heavy CP even scalar $H$. The couplings relevant to diphoton decay are obtained from quartic couplings including $\Phi, \varphi$ and charged scalar fields;

$$L \supset \sum_i \left[ \lambda_{\Phi i}^Q |\Phi|^2 |\phi_i^Q|^2 + \lambda_{\varphi i}^Q |\varphi|^2 |\phi_i^Q|^2 \right], \hspace{1cm} (IV.1)$$

where we denote charged scalar field with electric charge $Q$ as $\phi_i^Q$ in general. After $\Phi$ and $\varphi$ get VEV, relevant interactions for mass eigenstates are

$$L \supset \sum_i \left[ (\lambda_{\Phi i}^Q v \cos \theta - \lambda_{\varphi i}^Q v \sin \theta) h |\phi_i^Q|^2 + (\lambda_{\Phi i}^Q v \sin \theta + \lambda_{\varphi i}^Q v \cos \theta) H |\phi_i^Q|^2 \right]. \hspace{1cm} (IV.2)$$

Since we want to suppress contribution to $h \to \gamma \gamma$, we assume $\lambda_{\Phi i}^Q v \cos \theta \simeq \lambda_{\varphi i}^Q v \sin \theta$. Then interactions contributing to $H \to \gamma \gamma$ become

$$\sum \frac{\lambda_{\Phi i}^Q v \cos \theta}{H |\phi_i^Q|^2} = \sum \mu_{H\phi_i^Q} H |\phi_i^Q|^2, \hspace{1cm} (IV.3)$$

where $\mu_{H\phi_i^Q} = \lambda_{\varphi i}^Q v / \cos \theta$.

The heavy CP-even scalar $H$ can be produced by gluon fusion process via mixing with SM Higgs. The cross section is then obtained as $[192, 193]$

$$\sigma(gg \to H) \simeq \sin^2 \theta \times 0.85 \text{ pb}, \hspace{1cm} (IV.4)$$
FIG. 3: The contours of $\sigma(gg \to H)BR(H \to \gamma\gamma)$ (in unit of fb) and total width $\Gamma_H$ (in unit of GeV) in $\sin \theta - \mu_{H\phi\phi}$ plane for $N = 5, 7, 9, 11, 13$. All the charged scalar masses are taken to be 380 GeV. The purple dashed and the red dotted lines indicate constraint from diphoton search at 8 TeV for $R_{\gamma\gamma} = 2$ and 4 where the region above the lines are excluded.

at the LHC 13 TeV. Furthermore, $H$ can be produced by photon fusion, $pp(\gamma\gamma) \to H$, since effective $H\gamma\gamma$ coupling would be sizable due to charged scalar loop contributions. Here we apply the estimation of the cross section for photon fusion including both elastic and in-elastic scattering in Ref. [145]

$$\sigma(pp(\gamma\gamma) \to H \to \gamma\gamma + X)_{13\text{TeV}} = 10.8 \text{pb} \left( \frac{\Gamma_H}{45\text{GeV}} \right) \times BR^2(H \to \gamma\gamma), \quad \text{(IV.5)}$$
where $X$ indicate any other associated final states. Therefore total cross section for $pp \rightarrow H \rightarrow \gamma\gamma$ is obtained as

$$\sigma_{\gamma\gamma} = \sigma(gg \rightarrow H) BR(H \rightarrow \gamma\gamma) + \sigma_{\gamma-\text{fusion}}$$  \hspace{1cm} (IV.6)

where $\sigma_{\gamma-\text{fusion}}$ is given by Eq. (IV.5).

Through mixing with SM Higgs, $H$ decays into SM particles where the dominant partial decay widths are:

$$\Gamma(H \rightarrow W^+W^-) = \frac{g^2 m_W^2 \sin^2 \theta m_H^4 - 4m_H^2 m_W^2 + 12m_W^4}{64\pi m_H} \sqrt{1 - \frac{(2m_W)^2}{m_H^2}},$$  \hspace{1cm} (IV.7)

$$\Gamma(H \rightarrow ZZ) = \frac{1}{2\,64\pi} \frac{g^2 m_Z^2 \sin^2 \theta m_H^4 - 4m_H^2 m_Z^2 + 12m_Z^4}{m_Z^2} \sqrt{1 - \frac{(2m_Z)^2}{m_H^2}},$$  \hspace{1cm} (IV.8)

$$\Gamma(H \rightarrow t\bar{t}) = \frac{3m_t^2 \sin^2 \theta}{8\pi v^2} m_\phi \sqrt{1 - \frac{4m_t^2}{m_H^2}}.$$  \hspace{1cm} (IV.9)

Here partial decay widths for other fermion channels are subdominant. The decay process $H \rightarrow \gamma\gamma$ is induced by charged particle loops. The partial decay width is given by

$$\Gamma_{H \rightarrow \gamma\gamma} \approx \frac{\alpha^2 m_\phi^3}{256\pi^3} \left| \sum_{\psi_i} Q_i^2 \frac{\mu_{H\phi_i}}{2m_{\psi_i}} A_0(\tau_{\psi_i}) \right|^2,$$  \hspace{1cm} (IV.10)

where $A_0(x) = -x^2[x^{-1} - [\sin^{-1}(1/\sqrt{x})]^2]$ and $\tau_{\psi_i} = 4m_{\psi_i}^2/m_H^2$ and we omit SM particle contribution since they are small compared with charged scalar contributions. Note that we also have $H \rightarrow Z\gamma$ mode which is subdominant contribution and we omit the formula for decay width here.

The constraint from 8 TeV data should be taken into account. The most stringent constraint in our scenario is given by diphoton search at 8 TeV since our $BR(H \rightarrow \gamma\gamma)$ is large. The constraint is $\sigma_{8\text{TeV}}^{8\gamma\gamma} \equiv \sigma(gg \rightarrow H)^{8\text{TeV}} BR(H \rightarrow \gamma\gamma) + \sigma_{8\text{TeV}}^{\gamma-\text{fusion}} < 1.5 \text{ fb.}$  \hspace{1cm} (IV.11)

Here the ratios of 13 TeV cross section and that of 8 TeV are written as $\sigma(gg \rightarrow H)^{13\text{TeV}}/\sigma(gg \rightarrow H)^{8\text{TeV}} \simeq 5$ and $\sigma_{\gamma-\text{fusion}}^{13\text{TeV}}/\sigma_{\gamma-\text{fusion}}^{8\text{TeV}} \equiv R_{\gamma\gamma}$. The $R_{\gamma\gamma}$ is estimated to be $\sim 2$ but the uncertainty is large so that it can be $\sim 4$. Thus we investigate the constraint with $R_{\gamma\gamma} = 2$ and 4.
We then estimate the product of $H$ production cross section and branching ratio for diphoton channel $\sigma^\text{total}_{\gamma\gamma}$ for the cases of $N = 3, 5, 7, 9$ and $11$. For simplicity, we assume couplings $\mu_{H\phi^Q_i}$ take same value for all charged scalars. Also we choose mass of charged scalar as $m_{\phi^Q_i} = 380 \text{ GeV}$ to enhance loop function inside the diphoton decay width. The contours of $\sigma^\text{total}_{\gamma\gamma}$ and $\Gamma_H$ are shown in Fig. 3 by solid and dashed lines respectively for $N = \{5, 7, 9, 11, 13\}$, and the purple dashed and the red dotted lines indicate constraint from diphoton search at 8 TeV for $R_{\gamma\gamma} = 2$ and 4 where the region above the lines are excluded. We find that small $\sin \theta$ region is strongly constrained for $R_{\gamma\gamma} = 2$ but we can obtain $\sim 3 \text{ fb}$ cross section for all $\sin \theta$. On the other hand, we can obtain $\sim 5 \text{ fb}$ cross section for $R_{\gamma\gamma} = 4$. Furthermore the trilinear coupling can be less than 1 TeV for $7 \leq N$. We also find that the total decay width $\Gamma_H$ is $O(1 - 10) \text{ GeV}$ for the parameter region which explain the diphoton excess.

V. CONCLUSIONS AND DISCUSSIONS

In our paper, we have proposed a generalized Zee-Babu model with a global $U(1)_B$-$L$ symmetry, in which neutrino masses are induced at the two loop level. Here we have introduced vector like isospin doublet fermions with general $N/2$ hypercharges that can explain the discrepancy of the muon anomalous magnetic moment to the standard model (SM) sizably. Corresponding to each of the number of $N$, we have needed to introduce some multiply charged bosons in order to make the exotic fields decay into the standard model fields. Diphoton excess is explained by introducing several charged bosons, depending on the number of $N$. We have classified the model according to the number of $N$, and we have discussed what kind of models are in favor of explaining the sizable diphoton resonance as well as the muon anomalous magnetic moment.

We have estimated the product of $H$ production cross section and branching ratio for diphoton channel. Then the $O(1) \text{ TeV}$ trilinear coupling is required for $N = 5$ while the coupling can be smaller for larger $N$. Thus larger $N$ is preferred to satisfy tree level unitarity and explain the diphoton excess. We also find the total decay width in our scenario is $O(1 - 10) \text{ GeV}$. Furthermore we investigated constraint from diphoton search at 8 TeV and we find the parameter region which explain diphoton excess and can satisfy the constraint.

A Dirac type of dark matter can be involved in our theory without conflict of any phe-
nomenological point of views. However this analysis is beyond the scope.

Acknowledgments

H.O. thanks to Prof. Shinya Kanemura, Prof. Seong Chan Park, Dr. Kenji Nishiwaki, Dr. Yuta Orikasa, Dr. Ryoutaro Watanabe, and Dr. Kei Yagyu for fruitful discussions. H. O. is sincerely grateful for all the KIAS members, Korean cordial persons, foods, culture, weather, and all the other things.
