Abstract

We study random partitions \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_d) \) of \( n \) whose length is not bigger than a fixed number \( d \). Suppose a random partition \( \lambda \) is distributed according to the Jack measure, which is a deformation of the Plancherel measure with a positive parameter \( \alpha > 0 \). We prove that for all \( \alpha > 0 \), in the limit as \( n \to \infty \), the joint distribution of scaled \( \lambda_1, \ldots, \lambda_d \) converges to the joint distribution of some random variables from a traceless Gaussian \( \beta \)-ensemble with \( \beta = 2/\alpha \). We also give a short proof of Regev's asymptotic theorem for the sum of \( \beta \)-powers of \( f^\lambda \), the number of standard tableaux of shape \( \lambda \).

MSC-class: primary 60C05 ; secondary 05E10

Key words: Plancherel measure, Jack measure, random matrix, random partition, RSK correspondence

1 Introduction

A random partition is studied as a discrete analogue of eigenvalues of a random matrix. The most natural and studied random partition is a partition distributed according to the Plancherel measure for the symmetric group. The Plancherel measure chooses a partition \( \lambda \) of \( n \) with probability

\[
\mathbb{P}_{\text{Plan}}(\lambda) = \frac{(f^\lambda)^2}{n!},
\]

where \( f^\lambda \) is the degree of the irreducible representation of the symmetric group \( \mathfrak{S}_n \) associated with \( \lambda \). A random partition \( \lambda = (\lambda_1, \lambda_2, \ldots) \) chosen by the Plancherel measure is closely related to the Gaussian unitary ensemble (GUE) of random matrix theory. The GUE matrix is a Hermitian matrix whose entries are independently distributed according to the normal distribution. The probability density function for the eigenvalues \( x_1 \geq \cdots \geq x_d \) of the \( d \times d \) GUE matrix is proportional to

\[
e^{-\beta \sum_{i=1}^{d} x_i^2} \prod_{1 \leq i < j \leq d} (x_i - x_j)^\beta
\]
with $\beta = 2$. In [BOO] [J3] [O1] (see also [BDJ]), it is proved that, as $n \to \infty$, the joint distribution of the scaled random variables $(\lambda_i - 2\sqrt{n}) n^{-1/6}$, $i = 1, 2, \ldots$, according to $\mathbb{P}^\text{Plan}_n$ converges to a distribution function $F$. Meanwhile, the joint distribution of the scaled eigenvalues $(x_i - \sqrt{2d}) \sqrt{2d}^{1/6}$ of a $d \times d$ GUE matrix converges to the same function $F$ as $d \to \infty$ ([TW1]). Thus, roughly speaking, a limit distribution for $\lambda_i$ in $\mathbb{P}^\text{Plan}_n$ equals a limit distribution for eigenvalues $x_i$ of a GUE random matrix.

An analogue of the Plancherel measure on strict partitions (i.e., all non-zero $\lambda_i$ are distinct each other), called the shifted Plancherel measure, is studied in [Mat1] [Mat2], see also [TW3]. It is proved that the joint distribution of scaled $\lambda_i$ of the corresponding random partition also converges to the limit distribution for a GUE matrix. In addition, there are many recent works ([B] [BOS] [J1] [J2] [K] [O2] [TW2]), which evinces the connection between Plancherel random partitions and GUE random matrices.

In random matrix theory, there are two much-studied analogues of the GUE matrix, called the Gaussian orthogonal (GOE) and symplectic (GSE) ensemble random matrix, see standard references [Fo] [Mc]. The probability density function for the eigenvalues of the GOE and GSE matrix is proportional to the function given by (1.2) with $\beta = 1$ and $\beta = 4$, respectively. It is natural to consider a model of random partitions corresponding to the GOE and GSE matrix. This motivation is not new and one may recognize it in [BR1] [BR2] [BR3] [FNR] [FR]. In the present paper, we deal with a “$\beta$-version” of the Plancherel measure, called the Jack measure with parameter $\alpha := 2/\beta$ ([BO] [Fu1] [Fu2] [O2] [St]).

The Jack measure with a positive real parameter $\alpha > 0$ equips to each partition $\lambda$ of $n$ the probability

$$ \mathbb{P}^\text{Jack}_n(\lambda) = \frac{\alpha^n n!}{c_\alpha(\lambda)c'_\alpha(\lambda)}. $$

Here $c_\alpha(\lambda)$ and $c'_\alpha(\lambda)$ are defined by (2.1) below and are $\alpha$-analogues of the hook-length product of $\lambda$. We notice that the Jack measure with parameter $\alpha = 1$ agrees the Plancherel measure $\mathbb{P}^\text{Plan}_n$ because $\frac{n!}{c_1(\lambda)c'(1)} = \frac{n!}{c_1(1)} = f^\lambda$. One may regard a random partition distributed according to the Jack measure with parameter $\alpha = 2$ and $\alpha = 1/2$ as a discrete analogue of the GOE and GSE matrix, respectively. More generally, for any positive real number $\beta > 0$, the Jack measure with $\alpha = 2/\beta$ is the counterpart of the Gaussian $\beta$-ensemble (G$\beta$E) with the probability density function proportional to (1.2).

We are interested in finding out an explicit connection between Jack measures and the G$\beta$E. In the present paper, we deal with random partitions with at most $d$ non-zero $\lambda_j$’s, where $d$ is a fixed positive integer. Let $\mathcal{P}_n(d)$ be the set of such partitions of $n$, i.e., $\lambda \in \mathcal{P}_n(d)$ is a weakly-decreasing $d$-length sequence $(\lambda_1, \ldots, \lambda_d)$ of non-negative integers such that $\lambda_1 + \cdots + \lambda_d = n$. Let $\lambda^{(n)} = (\lambda_1^{(n)}, \ldots, \lambda_d^{(n)})$ be a random partition in $\mathcal{P}_n(d)$ chosen with the Jack measure. Then, for each $1 \leq i \leq d$, the function $\lambda^{(n)} \mapsto \lambda_i^{(n)}$ defines a random variable on $\mathcal{P}_n(d)$. Śniady [Sn] proved that, if $\alpha = 1$ (the Plancherel case), the joint distribution of the random variables $\left( \sqrt{\frac{d}{n}} (\lambda_i^{(n)} - \frac{n}{d}) \right)_{1 \leq i \leq d}$ converges, as $n \to \infty$, to the joint distribution of the eigenvalue of a $d \times d$ traceless GUE matrix. (Note that our definition of the probability density function (1.2) with $\beta = 2$ is slightly different from Śniady’s one.) Here the traceless GUE matrix is a GUE matrix whose trace is zero.
Our goal in the present paper is to extend Śniady’s result to Jack measures with any parameter \( \alpha \). Specifically, let a random partition \( \lambda^{(n)} \in \mathcal{P}_n(d) \) to be chosen in the Jack measure. Then, we prove that the joint distribution of the random variables \( \left( \sqrt{\frac{\alpha d}{n}} (\lambda_i^{(n)} - \frac{n}{d}) \right)_{1 \leq i \leq d} \) converges to the joint distribution of eigenvalues in the traceless \( G_{\beta}E \) with \( \beta = 2/\alpha \). The explicit statement of our main result is given in §2 and its proof is given in §4.

In §3, we focus on Jack measures with \( \alpha = 2 \) and \( \alpha = \frac{1}{2} \). These are discrete analogues of GOE and GSE random matrices. Via the RSK correspondence between permutations and pairs of standard Young tableaux, we see connections with random involutions.

In the final section §5, we give a short proof of Regev’s asymptotic theorem. Regev \([\text{Re}]\) gave an asymptotic behavior for the sum \( \sum_{\lambda \in \mathcal{P}_n} (f^\lambda)^\beta \) in the limit \( n \to \infty \). In this limit value, the normalization constant of the traceless \( G_{\beta}E \) appears. Regev’s asymptotic theorem is an important classical result which indicates a connection between Plancherel random partitions and random matrix theory. Applying the technique used in the proof of our main result, we obtain a short proof of Regev’s asymptotic theorem.

Throughout this paper, we let \( d \) to be a fixed positive integer.

2 Main result

2.1 Jack measures with parameter \( \alpha > 0 \)

We review fundamental notations for partitions according to \([\text{Sa}, \text{Mac}]\). A partition \( \lambda = (\lambda_1, \lambda_2, \ldots) \) is a weakly decreasing sequence of non-negative integers such that \( \lambda_j = 0 \) for \( j \) sufficiently large. Put

\[
\ell(\lambda) = \# \{ j \geq 1 \mid \lambda_j > 0 \}, \quad |\lambda| = \sum_{j \geq 1} \lambda_j
\]

and call them the length and weight of \( \lambda \), respectively. If \(|\lambda| = n\), we say that \( \lambda \) is a partition of \( n \). We identify \( \lambda \) with the corresponding Young diagram \( \{(i, j) \in \mathbb{Z}^2 \mid 1 \leq i \leq \ell(\lambda), 1 \leq j \leq \lambda_i\} \).

We write \((i, j) \in \lambda \) if \((i, j)\) is contained in the Young diagram of \( \lambda \). Denote by \( \lambda' = (\lambda_1', \lambda_2', \ldots) \) the conjugate partition of \( \lambda \), i.e., \((i, j) \in \lambda' \) if and only if \((j, i) \in \lambda \).

Let \( \alpha \) be a positive real number. For each partition \( \lambda \), we put \((\text{Mac}, \text{VI}, (10.21))]\)

\[
c(\alpha) = \prod_{(i, j) \in \lambda} (\alpha(\lambda_i - j) + (\lambda_j' - i) + 1), \quad c'(\alpha) = \prod_{(i, j) \in \lambda} (\alpha(\lambda_i - j) + (\lambda_j' - i) + \alpha).
\]

Let \( \mathcal{P}_n \) be the set of all partitions of \( n \). Define

\[
\mathbb{P}^{\text{Jack}, \alpha}_n(\lambda) = \frac{\alpha^n n!}{c(\alpha)c'(\alpha)}
\]

for each \( \lambda \in \mathcal{P}_n \). This is a probability measure on \( \mathcal{P}_n \), i.e., \( \sum_{\lambda \in \mathcal{P}_n} \mathbb{P}^{\text{Jack}, \alpha}_n(\lambda) = 1 \), see \([\text{Mac}, \text{VI}, (10.32)]\). We call this the Jack measure with parameter \( \alpha \) \((\text{Fu1}, \text{Fu2})\). This is sometimes called
the Plancherel measure with parameter $\theta := \alpha^{-1}$ ([BO, St]). The terminology “Jack measure” is derived from Jack polynomials ([Mac, VI.10]).

When $\alpha = 1$, we have $c_\lambda(1) = c'_\lambda(1) = H_\lambda$, where

$$H_\lambda = \prod_{(i,j) \in \lambda} ((\lambda_i - j) + (\lambda'_j - i) + 1)$$

is the hook-length product. By the well-known hook formula (see e.g. [Sa, Theorem 3.10.2])

(2.3) $$f_\lambda = \frac{n!}{H_\lambda},$$

the measure $P_{\text{Jack}, 1}^n$ is just the ordinary Plancherel measure $P_{\text{Plan}}^n$ defined in (1.1). The measure $P_{\text{Jack}, 2}^n$ is the Plancherel measure associated with the Gelfand pair $(S_{2n}, K_n)$, where $K_n (\cong S_2 \wr S_n)$ is the hyperoctahedral group in $S_{2n}$, see [Fu2, §4.4]. From the equality $c'_\lambda(\alpha) = \alpha |\lambda| c_\lambda'(\alpha - 1)$,

we have the duality

$$P_{\text{Jack}, \alpha}^n(\lambda) = P_{\text{Jack}, \alpha - 1}^n(\lambda'),$$

for any $\lambda \in P_n$ and $\alpha > 0$.

Denote by $P_n(d)$ the set of partitions $\lambda$ in $P_n$ of length $\leq d$. We consider the restricted Jack measure with parameter $\alpha$ on $P_n(d)$:

(2.4) $$P_{\text{Jack}, \alpha}^n(d)(\lambda) = \frac{1}{C_{n,d}(\alpha) c_\lambda(\alpha) c'_\lambda(\alpha)}, \quad \lambda \in P_n(d),$$

where

(2.5) $$C_{n,d}(\alpha) = \sum_{\mu \in P_n(d)} \frac{1}{c_\mu(\alpha) c'_\mu(\alpha)}.$$

By the definition (2.2) of the Jack measure, $C_{n,d}(\alpha) = (\alpha^n n!)^{-1}$ if $d \geq n$.

### 2.2 Traceless Gaussian matrix ensembles

Let

$$\mathcal{S}_d = \{(x_1, \ldots, x_d) \in \mathbb{R}^d \mid x_1 \geq \cdots \geq x_d, \ x_1 + \cdots + x_d = 0\}.$$

and let $\beta$ be a positive real number. We equip the set $\mathcal{S}_d$ with the probability density function

(2.6) $$\frac{1}{Z_d(\beta)} e^{-\frac{\beta}{2} \sum_{j=1}^d x_j^2} \prod_{1 \leq j < k \leq d} (x_j - x_k)^\beta,$$

where the normalization constant $Z_d(\beta)$ is defined by

(2.7) $$Z_d(\beta) = \int_{\mathcal{S}_d} e^{-\frac{\beta}{2} \sum_{j=1}^d x_j^2} \prod_{1 \leq j < k \leq d} (x_j - x_k)^\beta dx_1 \cdots dx_{d-1}.$$

Here the integral runs over $(x_1, \ldots, x_{d-1}) \in \mathbb{R}^{d-1}$ such that $(x_1, \ldots, x_d) \in \mathcal{S}_d$ with $x_d := -(x_1 + \cdots + x_{d-1})$. The explicit expression of $Z_d(\beta)$ is obtained in [Re] but we do not need
We call the set $\mathcal{H}_d$ with probability density \( p_0(x) \) the traceless Gaussian $\beta$-ensemble (G$\beta$E$_0$).

If $\beta = 1, 2,$ or $4$, the G$\beta$E$_0$ gives the distribution of the eigenvalues of a traceless Gaussian random matrix $X$ as follows (see [Fo, Me]). Let $\beta = 1$. We equip the space of $d \times d$ symmetric real matrices $X$ such that $\text{tr} X = 0$ with the probability density function proportional to $e^{-\frac{1}{2} \text{tr}(X^2)}$. Then we call the random matrix $X$ a traceless Gaussian orthogonal ensemble (GOE$_0$) random matrix. Let $\beta = 2$. Then we consider the space of $d \times d$ Hermitian complex matrices $X$ such that $\text{tr} X = 0$ with the probability density function proportional to $e^{-\text{tr}(X^2)}$. We call $X$ a traceless Gaussian unitary ensemble (GUE$_0$) random matrix. Let $\beta = 4$. Then we consider the space of $d \times d$ Hermitian quaternion matrices $X$ such that $\text{tr} X = 0$ with the probability density function proportional to $e^{-\text{tr}(X^2)}$. We call $X$ a traceless Gaussian symplectic ensemble (GSE$_0$) random matrix.

The GOE$_0$, GUE$_0$, and GSE$_0$ matrices are the restriction of the ordinary GOE, GUE, GSE matrices to matrices whose trace is zero. From the well-known fact in random matrix theory, the probability density function of eigenvalues of $X$ is given by (2.6) with $\beta = 1$ (GOE$_0$), $\beta = 2$ (GUE$_0$), or $\beta = 4$ (GSE$_0$). We note that for general $\beta > 0$, Dumitriu and Edelman [DE] give tridiagonal matrix models for Gaussian $\beta$-ensembles.

### 2.3 Main theorem

Let $(x_{G\beta E_0}^1, x_{G\beta E_0}^2, \ldots, x_{G\beta E_0}^d)$ be a sequence of random variables according to the G$\beta$E$_0$. Equivalently, the joint probability density function for $(x_{G\beta E_0}^i)_{1 \leq i \leq d}$ is given by (2.6). Our main result is as follows.

**Theorem 2.1.** Let $\alpha$ be any positive real number and put $\beta = 2/\alpha$. Let $\lambda^{(n)} = (\lambda_1^{(n)}, \ldots, \lambda_d^{(n)})$ be a random partition in $P_n(d)$ chosen with probability $P_{\lambda^{(n)}}$. Then, as $n \to \infty$, the random variables

\[
\left( \sqrt{\frac{\alpha d}{n}} \left( \lambda_i^{(n)} - \frac{n}{d} \right) \right)_{1 \leq i \leq d}
\]

converge to $(x_{G\beta E_0}^i)_{1 \leq i \leq d}$ in joint distribution.

The case with $\alpha = 1$ (and so $\beta = 2$) of Theorem 2.1 is proved in [Sn]. (We remark that the definition of the density of a GUE$_0$ matrix in [Sn] is slightly different from us.)

We give the proof of Theorem 2.1 in Section 4.

### 3 Jack measures with $\alpha = 2$ or $\frac{1}{2}$ and RSK correspondences

In this section, we deal with Jack measures with parameter $\alpha = 2$ and $\alpha = \frac{1}{2}$. Our goal is to obtain a limit theorem for a random involutive permutation as a corollary of Theorem 2.1.

**Lemma 3.1.** For each $\lambda \in P_n$ we have

\[
c_{\lambda}(2)c'_{\lambda}(2) = H_{2\lambda}, \quad c_{\lambda}(1/2)c'_{\lambda}(1/2) = 2^{-2n}H_{\lambda \cup \lambda},
\]

where $2\lambda = (2\lambda_1, 2\lambda_2, \ldots)$ and $\lambda \cup \lambda = (\lambda_1, \lambda_2, \lambda_2, \ldots)$. 

Proof. Put $\mu = 2\lambda$. Then, since $\mu_i = 2\lambda_i$ and $\mu'_{2j-1} = \mu'_{2j} = \lambda'_j$ for any $i, j \geq 1$, we have
\[
H_{\mu} = \prod_{(i,j)\in \mu, \ j: \text{odd}} (\mu_i - j + \mu'_j - i + 1) \times \prod_{(i,j)\in \mu, \ j: \text{even}} (\mu_i - j + \mu'_j - i + 1)
\]
\[
= \prod_{(i,j)\in \lambda} (2\lambda_i - (2j - 1) + \lambda'_j - i + 1) \times \prod_{(i,j)\in \lambda} (2\lambda_i - 2j + \lambda'_j - i + 1)
\]
\[
= c'_\lambda(2)c_\lambda(2).
\]
Applying the equality $c'_\lambda(\alpha) = \alpha^n c_\lambda(\alpha^{-1})$ to the above identity, we see that $2^{2n}c_\lambda(1/2)c'_\lambda(1/2) = H_{\lambda_2} = H_{(\lambda_\lambda)'} = H_{\lambda_\lambda}$. \qed

By this lemma, the Jack measures with parameter $\alpha = 2$ and $\frac{1}{2}$ are expressed as follows.
\[
\mathbb{P}_{n,2}(\lambda) = \frac{f_{2\lambda}}{(2n-1)!!}, \quad \mathbb{P}_{n,\frac{1}{2}}(\lambda) = \frac{f_{\lambda_\lambda}}{(2n-1)!!}.
\]

Recall the Robinson-Schensted-Knuth (RSK) correspondence (see e.g. [Sa, Chapter 3]). There exists a one-to-one correspondence between elements in $\mathcal{S}_N$ and ordered pairs of standard Young tableaux of same shape whose size is $N$ ([Sa, Theorem 3.1.1]). Let $\sigma \in \mathcal{S}_N$ correspond to the ordered pair $(P, Q)$ of standard Young tableaux of shape $\mu \in P_N$. Then, the length $L_{in}(\sigma)$ of the longest increasing subsequence in $(\sigma(1), \ldots, \sigma(N))$ is equal to $\mu_1$. Similarly, the length $L_{de}(\sigma)$ of the longest decreasing subsequence in $\sigma$ is equal to $\mu'_1$ ([Sa, Theorem 3.3.2]). Furthermore, the permutation $\sigma^{-1}$ corresponds to the pair $(Q, P)$ ([Sa, Theorem 3.6.6]). In particular, there exists a one-to-one correspondence between involutions $\sigma$ (i.e. $\sigma = \sigma^{-1}$) in $\mathcal{S}_N$ and standard Young tableaux of size $N$.

Let $\sigma$ be an involution with $k$ fixed points. Then the standard Young tableau corresponding to $\sigma$ has exactly $k$ columns of odd length ([Sa, Exercises 3.12.7(b)]). Therefore, the number of fixed-point-free involutions $\sigma$ in $\mathcal{S}_{2n}$ such that $L_{in}(\sigma) \leq a$ and $L_{de}(\sigma) \leq b$ is equal to
\[
\sum_{\mu \in P_{2n}, \mu': \text{even}} \sum_{\mu_1 \leq a, \mu'_1 \leq 2b} f^\mu = \sum_{\lambda \in P_n, \lambda_1 \leq a, \ell(\lambda) \leq b} \sum_{\lambda \in P_n, \lambda_1 \leq b, \ell(\lambda) \leq a} f^{\lambda_\lambda},
\]
where the first sum runs over partitions $\mu$ in $P_{2n}$ whose conjugate partition $\mu'$ is even, (i.e. all $\mu'_j$ are even) satisfying $\mu_1 \leq a$ and $\mu'_1 \leq 2b$.

Note that the values $C_{n,d}(1/2)$ and $C_{n,d}(2)$ are expressed by a matrix integral. Using Rains' result [Ra], we have
\[
C_{n,d}(1/2) = \frac{2^{2n}}{(2n)!} \sum_{\lambda \in P_n(d)} f^{\lambda_\lambda} = \frac{2^{2n}}{(2n)!} \int_{Sp(2d)} \text{tr}(S)^{2n} dS,
\]
where the integral runs over the symplectic group with its normalized Haar measure. Similarly,
\[
C_{n,d}(2) = \frac{1}{(2n)!} \sum_{\lambda \in P_n(d)} f^{2\lambda} = \frac{1}{(2n)!} \int_{O(d)} \text{tr}(O)^{2n} dO,
\]
where the integral runs over the orthogonal group with its normalized Haar measure.

Let $S^0_{2n}$ be the subset in $S_{2n}$ of fixed-point-free involutions. Equivalently,

$$S^0_{2n} = \{ \sigma \in S_{2n} \mid \text{The cycle-type of } \sigma \text{ is } (2^n) \}.$$  

We pick $\sigma \in S^0_{2n}$ at random according to the uniformly distributed probability, i.e. the probability of all $\sigma \in S^0_{2n}$ are equal.

**Lemma 3.2.** 1. The distribution function $P_{\text{Jack},1/2,(\lambda_1 \leq h)}$ of the random variable $\lambda_1$ with respect to $P_{\text{Jack},1/2,(\lambda_1)}$ is equal to the ratio

$$\frac{\#\{ \sigma \in S^0_{2n} \mid L^{\text{de}}(\sigma) \leq 2d \text{ and } L^{\text{in}}(\sigma) \leq h \}}{\#\{ \sigma \in S^0_{2n} \mid L^{\text{de}}(\sigma) \leq 2d \}},$$

which is the distribution function of $L^{\text{in}}$ for a random involution $\sigma \in S^0_{2n}$ such that $L^{\text{de}}(\sigma) \leq 2d$.

2. The distribution function $P_{\text{Jack},2,(\lambda_1 \leq h)}$ of the random variable $\lambda_1$ with respect to $P_{\text{Jack},2,(\lambda)}$ is equal to the ratio

$$\frac{\#\{ \sigma \in S^0_{2n} \mid L^{\text{in}}(\sigma) \leq d \text{ and } L^{\text{de}}(\sigma) \leq 2h \}}{\#\{ \sigma \in S^0_{2n} \mid L^{\text{in}}(\sigma) \leq d \}},$$

which is the distribution function of $L^{\text{in}}/2$ for a random involution $\sigma \in S^0_{2n}$ such that $L^{\text{in}}(\sigma) \leq d$.

By the above lemma and Theorem 2.1, we obtain the following corollary.

**Corollary 3.3.** 1. (The $\alpha = 1/2$ case) Let $\sigma \in S^0_{2n}$ be a random fixed-point-free involution with the longest decreasing subsequence of length at most $2d$. Then, as $n \to \infty$, the distribution of $\sqrt{\frac{d}{2n}} (L^{\text{in}}(\sigma) - \frac{n}{2})$ converges to the distribution for the largest eigenvalue of a GSE$_0$ random matrix of size $d$.

2. (The $\alpha = 2$ case) Let $\sigma \in S^0_{2n}$ be a random fixed-point-free involution with the longest increasing subsequence of length at most $d$. Then, as $n \to \infty$, the distribution of $\sqrt{\frac{2d}{n}} \left( \frac{L^{\text{de}}(\sigma)}{2} - \frac{n}{3} \right)$ converges to the distribution for the largest eigenvalue of the GOE$_0$ random matrix of size $d$.

The $\alpha = 1$ version of this corollary appears in [Sn, Corollary 4].

## 4 Proof of Theorem 2.1

### 4.1 Step 1

The following explicit formula for $c_\lambda(\alpha)$ and $c'_\lambda(\alpha)$ appears in the proof of Lemma 3.5 in [BO].
Lemma 4.1. For any \( \alpha > 0 \) and \( \lambda \in \mathcal{P}_n(d) \),

\[
c_\lambda(\alpha) = \alpha^n \prod_{1 \leq i < j \leq d} \frac{\Gamma(\lambda_i - \lambda_j + (j - i)/\alpha)}{\Gamma((j - i)/\alpha)} \cdot \prod_{i=1}^{d} \frac{\Gamma(\lambda_i + (d - i + 1)/\alpha)}{\Gamma(1/\alpha)},
\]

\[
c'_\lambda(\alpha) = \alpha^n \prod_{1 \leq i < j \leq d} \frac{\Gamma(\lambda_i - \lambda_j + (j - i - 1)/\alpha + 1)}{\Gamma((j - i + 1)/\alpha)} \cdot \prod_{i=1}^{d} \Gamma(\lambda_i + (d - i)/\alpha + 1).
\]

Proof. For each \( i \geq 1 \), let \( m'_i = m_i(\lambda') \) be the multiplicity of \( i \) in \( \lambda' = (\lambda'_1, \lambda'_2, \ldots) \). Then one observes

\[
\prod_{i=1}^{r} \prod_{j : \lambda'_j = r} (\lambda_i - j + (\lambda'_j - i + 1)/\alpha) = \prod_{i=1}^{r} \prod_{p=1}^{m'_i} (m'_i + m'_{i+1} + \cdots + m'_{r-1} + p - 1 + (r - i + 1)/\alpha)
\]

for each \( 1 \leq r \leq d \). Since \( m'_1 = \lambda_i - \lambda_{i+1} \), we have

\[
c_\lambda(\alpha) = \alpha^n \prod_{(i,j) \in \lambda} (\lambda_i - j + (\lambda'_j - i + 1)/\alpha)
\]

\[
= \alpha^n \prod_{r=1}^{d} \prod_{i=1}^{r} \prod_{p=1}^{\lambda_{r-\lambda_{r+1}}} (\lambda_i - \lambda_r + p - 1 + (r - i + 1)/\alpha)
\]

\[
= \alpha^n \prod_{r=i}^{d} \prod_{j=1}^{\lambda_{r-\lambda_{r+1}}} ((r - i + 1/\alpha))_{\lambda_i - \lambda_{r+1}}.
\]

Here \( (a)_k = \Gamma(a + k)/\Gamma(a) \) is the Pochhammer symbol. We moreover see that

\[
\alpha^{-n} c_\lambda(\alpha) = \prod_{i=1}^{d} \frac{(1/\alpha)_{\lambda_i - \lambda_{i+1}} (2/\alpha)_{\lambda_i - \lambda_{i+2}} \cdots ((d - i + 1/\alpha))_{\lambda_i - \lambda_{d+1}}}{1 \cdots ((d - i + 1/\alpha))_{\lambda_i - \lambda_{d}}}. \prod_{i=1}^{d} ((d - i + 1/\alpha))_{\lambda_i}.
\]

Now the first product equals

\[
\prod_{1 \leq i < j \leq d} \frac{\Gamma(\lambda_i - \lambda_j + (j - i)/\alpha)}{\Gamma((j - i)/\alpha)} \cdot \prod_{i=1}^{d} \frac{\Gamma((j - i + 1)/\alpha)}{\Gamma(\lambda_i - \lambda_j + (j - i + 1)/\alpha)}
\]

\[
= \prod_{1 \leq i < j \leq d} \frac{\Gamma(\lambda_i - \lambda_j + (j - i)/\alpha)}{\Gamma(\lambda_i - \lambda_j + (j - i + 1)/\alpha)} \cdot \prod_{i=1}^{d-1} \frac{\Gamma((d - i + 1)/\alpha)}{\Gamma(1/\alpha)},
\]

and the second product equals

\[
\prod_{i=1}^{d} \frac{\Gamma(\lambda_i + (d - i + 1)/\alpha)}{\Gamma((d - i + 1)/\alpha)}.
\]

Thus we obtain the desired expression for \( c_\lambda(\alpha) \). Similarly for \( c'_\lambda(\alpha) \). \( \square \)
4.2 Step 2

The discussion in this subsection is a slight generalization of the one in [Sn].

We put

\[ \xi_r^{(n)} = \frac{r - \frac{n}{d}}{\sqrt{\frac{d}{n}}} \]

for each \( r \in \mathbb{Z} \). For any positive real number \( \theta > 0 \), we define the function \( \phi_{n,\theta} : \mathbb{R} \to \mathbb{R} \) which is constant on the interval of the form \( I_r^{(n)} = [\xi_r^{(n)}, \xi_{r+1}^{(n)}) \) for each integer \( r \), and such that

\[
\phi_{n,\theta}(\xi_r^{(n)}) = \begin{cases} 1 & \text{if } r \text{ is non-negative}, \\ \frac{1}{1F_1(1,\frac{n}{d};\theta, \frac{n}{d})} \Gamma(\theta) r + \frac{n}{d} & \text{if } r \text{ is negative}. \end{cases}
\]

Here \( 1F_1(a; b; x) = \sum_{r=0}^{\infty} \frac{(a)_r x^r}{(b)_r r!} \) is the hypergeometric function of type \((1, 1)\). The following asymptotics follows from [AAR, Corollary 4.2.3]:

\[
1F_1 \left( 1; \theta; \frac{n}{d} \right) \sim \frac{e^{\frac{n}{d} \Gamma(\theta)}}{\Gamma(\theta) \left( \frac{n}{d} \right)^{\theta-1}} \quad \text{as } n \to \infty.
\]

The function \( \phi_{n,\theta} \) is a probability density function on \( \mathbb{R} \). Indeed, since \( \mathbb{R} = \bigcup_{r \in \mathbb{Z}} I_r^{(n)} \) and since the volume of each \( I_r^{(n)} \) is \( \xi_r^{(n)} - \xi_r^{(n)} = \sqrt{\frac{d}{n}} \), we have

\[
\int_{\mathbb{R}} \phi_{n,\theta}(y) dy = \sum_{r=0}^{\infty} \sqrt{\frac{d}{n}} \phi_{n,\theta}(\xi_r^{(n)}) = \frac{1}{1F_1(1; \theta; \frac{n}{d})} \sum_{r=0}^{\infty} \frac{(\frac{n}{d})^r}{(\theta)_r} = 1.
\]

We often need the equation

\[
\frac{1}{\Gamma(r + \theta)} = \frac{1}{1F_1(1; \theta; \frac{n}{d})} \phi_{n,\theta}(\xi_r^{(n)}) \sim \frac{e^{\frac{n}{d} \Gamma(\theta)}}{\Gamma(\theta) \left( \frac{n}{d} \right)^{\theta-1}} \phi_{n,\theta}(\xi_r^{(n)}),
\]

as \( n \to \infty \), for any fixed \( \theta > 0 \) and a non-negative integer \( r \). Here we have used (4.1).

The following lemma generalizes [Sn, Lemma 5] slightly.

**Lemma 4.2.** For any \( \theta > 0 \) and \( y \in \mathbb{R} \), we have

\[
\lim_{n \to \infty} \phi_{n,\theta}(y) = \frac{1}{\sqrt{2\pi}} e^{-\frac{y^2}{2}}.
\]

Furthermore, there exists a constant \( C = C_\theta \) such that

\[
\phi_{n,\theta}(y) < Ce^{-|y|}
\]

holds true for all \( n \) and \( y \).
Proof. Fix $y \in \mathbb{R}$. Let $c = \frac{n}{a}$ and let $r = r(y, c)$ be an integer such that $y \in I_r^{(n)}$, i.e., $r = [c + y\sqrt{c}]$. We may suppose that $r$ is positive because $r$ is large when $n$ is large. By (4.2) and the asymptotics

\begin{equation}
\Gamma(r + \theta) \sim \Gamma(r)r^\theta \quad \text{for } \theta \text{ fixed and as } r \to \infty,
\end{equation}

we see that

\[
\phi_n;\theta(y) \sim c^{\theta-1} e^{-c y + \frac{1}{2}} \frac{1}{\Gamma(\theta + r)} \sim \left(\frac{c}{r}\right)^{\theta-1} e^{-c y + \frac{1}{2}} \frac{1}{r!} = \left(\frac{c}{r}\right)^{\theta-1} \phi_n;1(y) \sim \phi_n;1(y)
\]

as $n \to \infty$ (so $c \to \infty$). Therefore we may assume $\theta = 1$ in order to prove (4.3). Using Stirling’s formula $\log r! = (r + \frac{1}{2}) \log r - r + \frac{\log 2\pi}{2} + O(r^{-1})$, we have

\[
\log \phi_n;1(y) = \log \phi_n;1(\xi^{(n)}_r) = \left( r + \frac{1}{2} \right) \log c - c - \log r!
\]

\[
= - \left( c + \xi^{(n)}_r \sqrt{c} + \frac{1}{2} \right) \log \left( 1 + \frac{\xi^{(n)}_r}{\sqrt{c}} \right) + \xi^{(n)}_r \sqrt{c} - \log \frac{2\pi}{2} + O(c^{-1})
\]

\[
= - \left( c + \xi^{(n)}_r \sqrt{c} + \frac{1}{2} \right) \left( \frac{\xi^{(n)}_r}{\sqrt{c}} - \left( \frac{\xi^{(n)}_r}{\sqrt{c}} \right)^2 - \log 2 + O(c^{-1}) \right) + \xi^{(n)}_r \sqrt{c} - \log \frac{2\pi}{2} + O(c^{-1})
\]

\[
= - \left( \frac{\xi^{(n)}_r}{2} \right)^2 - \log \frac{2\pi}{2} + O(c^{-\frac{1}{2}})
\]

as $c \to \infty$. Since $y = \xi^{(n)}_r + O(c^{-\frac{1}{2}})$, we obtain (4.3).

In order to prove (4.1), we consider the function

\[
g_\theta(y, a) = -a \log \left( 1 + \frac{y}{a} + \frac{\theta - 1}{a^2} \right)
\]

for $(y, a) \in \mathbb{R} \times \mathbb{R}_{>0}$. Then, for each positive integer $r$,

\[
\frac{\log \phi_{n;\theta}(\xi^{(n)}_r)}{\xi^{(n)}_r - \xi^{(n)}_{r-1}} = -\sqrt{\frac{n}{d}} \log \left( 1 + \frac{\xi^{(n)}_r}{\sqrt{\frac{n}{d}}} + \frac{\theta - 1}{\sqrt{\frac{n}{d}}} \right) = g_\theta \left( \xi^{(n)}_r, \sqrt{\frac{n}{d}} \right).
\]

It is easy to see that $g_\theta(y, a) > 1 \iff y < a(e^{-1/a} - 1) - \frac{\theta-1}{a}$. Take a negative number $D_1$ such that $D_1 < -1 + \min\{0, -(\theta - 1)\sqrt{d}\}$. Since $a(e^{-1/a} - 1) > -1$ for all $a > 0$, if $\xi^{(n)}_r < D_1$, then we have $\xi^{(n)}_r < \sqrt{\frac{n}{d}}(e^{-\sqrt{\frac{n}{d}}} - 1) - \frac{\theta-1}{\sqrt{\frac{n}{d}}}$, which is equivalent to $g_\theta \left( \xi^{(n)}_r, \sqrt{\frac{n}{d}} \right) > 1$. Therefore

\begin{equation}
\phi_{n;\theta}(\xi^{(n)}_r)e^{-\xi^{(n)}_{r-1}} < \phi_{n;\theta}(\xi^{(n)}_r)e^{-\xi^{(n)}_r}.
\end{equation}

Similarly, we see that $g_\theta(y, a) < -1 \iff y > a(e^{1/a} - 1) - \frac{\theta-1}{a}$. Since the function $a(e^{1/a} - 1)$ in $a$ is monotonically decreasing on $(0, \infty)$ and $\lim_{a \to +0} a(e^{1/a} - 1) = +\infty$, we can take a large
positive constant $D'_2$ such that $\sqrt{\frac{n}{d}}(e^{\sqrt{\frac{n}{d}}} - 1) < D'_2$ for all $n$. Take a positive number $D_2$ such that $D_2 > D'_2 + \max\{0, -(\theta - 1)\sqrt{d}\}$. Then, if $\xi^{(n)}_r > D_2$, we have $\xi^{(n)}_r > \sqrt{\frac{n}{d}}(e^{\sqrt{\frac{n}{d}}} - 1) - \frac{\theta - 1}{\sqrt{d}}$ for any $n$, which is equivalent to $g_{\theta}\left(\xi^{(n)}_r, \sqrt{\frac{n}{d}}\right) < -1$. Therefore

\begin{equation}
(4.7) \quad \phi_{n, \theta}(\xi^{(n)}_r)e^{\xi^{(n)}_r} < \phi_{n, \theta}(\xi^{(n)}_{r-1})e^{\xi^{(n)}_{r-1}}.
\end{equation}

The equation (4.6) implies that there exists a constant $C_1$ such that $\phi_{n, \theta}(y)e^{\left|y\right|} < C_1$ for $y$ sufficiently smaller than $D_1$. Similarly, the equation (4.7) implies that there exists a constant $C_2$ such that $\phi_{n, \theta}(y)e^{\left|y\right|} < C_2$ for $y$ sufficiently bigger than $D_2$. When $y$ belongs to a neighborhood of the interval $[D_1, D_2]$, the inequality (4.4) holds from the convergence (4.3). Thus, there exists a constant $C$ such that $\phi_{n, \theta}(y) < Ce^{-\left|y\right|}$ for all $y$.

4.3 Step 3

By Lemma 4.1 we have

\[ \frac{1}{c\lambda(\alpha)c'_{\lambda}(\alpha)} = \alpha^{-2n}\Gamma(1/\alpha)^d \prod_{i=1}^{4} F_i(\lambda_1, \ldots, \lambda_d) \]

where the functions $F_i$ are defined by

\[ F_1(r_1, \ldots, r_d) = \prod_{1 \leq i < j \leq d} (r_i - r_j + (j - i)/\alpha), \]

\[ F_2(r_1, \ldots, r_d) = \prod_{1 \leq i < j \leq d} \frac{\Gamma(r_i - r_j + (j - i + 1)/\alpha)}{\Gamma(r_i - r_j + (j - i - 1)/\alpha + 1)}, \]

\[ F_3(r_1, \ldots, r_d) = \prod_{i=1}^{d} \frac{1}{\Gamma(r_i + (d - i + 1)/\alpha)}, \]

\[ F_4(r_1, \ldots, r_d) = \prod_{i=1}^{d} \frac{1}{\Gamma(r_i + (d - i)/\alpha + 1)}, \]

for real numbers $r_1 \geq \cdots \geq r_d \geq 0$.

Lemma 4.3. Let $(y_1, \ldots, y_d) \in \mathcal{S}_d$ be real numbers such that $y_1 > y_2 > \cdots > y_d$, and let
\[ r_i = \frac{n}{d} + y_i \sqrt{\frac{d}{n}} \text{ for } 1 \leq i \leq d. \] Then as \( n \to \infty \)

\[
F_1(r_1, \ldots, r_d) \sim \left( \frac{n}{d} \right)^{\frac{d(d-1)}{2}} \prod_{1 \leq i < j \leq d} (y_i - y_j),
\]

\[
F_2(r_1, \ldots, r_d) \sim \left( \frac{n}{d} \right)^{\frac{d(d-1)}{2} - \frac{d}{2}} \prod_{1 \leq i < j \leq d} (y_i - y_j)^{\frac{d}{2} - 1},
\]

\[
F_3(r_1, \ldots, r_d) \sim \frac{e^n}{\left( \frac{n}{d} \right)^{n+\frac{d(d-1)}{2}+\frac{d}{2}}} \prod_{i=1}^{d} e^{-\frac{y_i^2}{2}},
\]

\[
F_4(r_1, \ldots, r_d) \sim \frac{e^n}{\left( \frac{n}{d} \right)^{n+\frac{d(d-1)}{2}+\frac{d}{2}}} \prod_{i=1}^{d} e^{-\frac{y_i^2}{2}}.
\]

Moreover, there exists a function \( P \) in \( d \) variables such that

\[
\frac{\left( \frac{n}{d} \right)^{2n+\frac{d(d-1)}{2}}}{e^{2n}} \prod_{i=1}^{d} F_i(r_1, \ldots, r_d) < P(y_1, \ldots, y_d) \prod_{i=1}^{d} e^{-|y_i|}
\]

for all \( y_1, \ldots, y_d \) and \( n \), and such that

\[
P(y_1, \ldots, y_d) = O(|y_1|^{k_1} \ldots |y_d|^{k_d}) \quad \text{as } |y_1|, \ldots, |y_d| \to \infty
\]

with some positive real numbers \( k_1, \ldots, k_d \).

**Proof.** It is immediate to see that

\[
F_1(r_1, \ldots, r_d) = \left( \frac{n}{d} \right)^{\frac{d(d-1)}{4}} \prod_{1 \leq i < j \leq d} \left( y_i - y_j + \sqrt{\frac{d}{n}}(j - i)/\alpha \right)
\]

so that the desired asymptotics for \( F_1 \) follows. The asymptotics for \( F_2 \) also follows by \( (4.5) \).

Using \( (4.2) \), we have

\[
F_3(r_1, \ldots, r_d) \sim \prod_{i=1}^{d} \left( \frac{n}{d} \right)^{\frac{d}{2}} e^{\frac{y_i^2}{2}} \phi_n(d, d+1)/\alpha (y_i) = \frac{e^n}{\left( \frac{n}{d} \right)^{n+\frac{d(d+1)}{2}+\frac{d}{2}}} \prod_{i=1}^{d} \phi_n(d, d+1)/\alpha (y_i).
\]

The desired asymptotics for \( F_3 \) follows from \( (4.3) \). Similarly for \( F_4 \).

Observe that there exist positive constants \( c_{ij} \) and \( d_{ij} \) such that

\[
(r_i - r_j + (j - i)/\alpha) \frac{\Gamma(r_i - r_j + (j - i + 1)/\alpha)}{\Gamma(r_i - r_j + (j - i - 1)/\alpha + 1)} \leq c_{ij}(r_i - r_j)^{2/\alpha} + d_{ij}
\]

for any \( r_1 \geq \cdots \geq r_d \). This implies that there exists a function \( P' \) in \( d \) variables such that

\[
F_1(r_1, \ldots, r_d) F_2(r_1, \ldots, r_d) < \left( \frac{n}{d} \right)^{\frac{d(d-1)}{2\alpha}} P'(y_1, \ldots, y_d)
\]
for all $n$ and satisfying the asymptotics given in (4.9). On the other hand, by (4.2), we have

$$F_3(r_1,\ldots,r_d)F_4(r_1,\ldots,r_d) < C'' \frac{e^{2n}}{(\frac{n}{\alpha})^{2n+2d}} \prod_{i=1}^{d} \phi_{n:(d-i+1)/\alpha}(y_i) \phi_{n:(d-i)/\alpha+1}(y_i)$$

with some constant $C''$. Therefore (4.8) follows from (4.4).

We extend $\frac{1}{c_{\lambda}(\alpha)c_{\lambda}^{\prime}(\alpha)}$ as follows. For all real numbers $r_1,\ldots,r_d \in \mathbb{R}$ satisfying $r_1+\cdots+r_d = n$, we put

$$c_{\lambda}(r_1,\ldots,r_d) = \begin{cases} \alpha^{-2n} \Gamma(1/\alpha)^{d} \prod_{i=1}^{d} F_i(r_1,\ldots,r_d) & \text{if } r_1 \geq \cdots \geq r_d \geq 0, \\ 0 & \text{otherwise.} \end{cases}$$

It follows by the above discussions that, for each $(y_1,\ldots,y_d) \in \mathcal{S}_d$, putting $r_i = \frac{n}{d} + y_i \sqrt{\frac{d}{n}}$ (1 $\leq i \leq d$),

$$\lim_{n \to \infty} \frac{\alpha^{2n} (\frac{n}{\alpha})^{2n+\frac{d(d+1)}{2n}}}{\Gamma(1/\alpha)^{d} e^{2n}} c_{\lambda}(r_1,\ldots,r_d) = e^{-\frac{y_1^2}{\lambda_1} - \cdots - \frac{y_d^2}{\lambda_d}} \prod_{1 \leq i < j \leq d} (y_i - y_j)^{2/\alpha}.$$  

Also, there exists a function $P$ satisfying (4.9) such that

$$\alpha^{2n} (\frac{n}{\alpha})^{2n+\frac{d(d+1)}{2n}} c_{\lambda}(r_1,\ldots,r_d) < e^{-2(|y_1|+\cdots+|y_d|)} P(y_1,\ldots,y_d)$$

for all $n$ and $(y_1,\ldots,y_d) \in \mathcal{S}_d$.

### 4.4 Step 4

Lemma 4.4.

$$\lim_{n \to \infty} C_{n,d}(\alpha) \frac{\alpha^{2n} (\frac{n}{\alpha})^{2n+\frac{d(d+1)}{2n}}}{\Gamma(1/\alpha)^{d} e^{2n}} = \alpha^{-\frac{d(d-1)}{2n} - \frac{d}{2}} Z_d(2/\alpha),$$

where $C_{n,d}(\alpha)$ is given by (2.5) and $Z_d(\beta)$ is given by (2.7).

**Proof.** By (4.13), we see that

$$\frac{\alpha^{2n} (\frac{n}{\alpha})^{2n+\frac{d(d+1)}{2n}}}{\Gamma(1/\alpha)^{d} e^{2n}} C_{n,d}(\alpha)$$

$$< \sum_{\lambda_1 \geq \cdots \geq \lambda_{d-1} \geq \lambda_d \geq 0} \left( \sqrt{\frac{d}{n}} \right)^{d-1} e^{-2(|\lambda_1|+\cdots+|\lambda_d|)} P(\xi_{\lambda_1},\ldots,\xi_{\lambda_d}) \quad (4.14)$$
for all \( n \). Each \( \xi_r^{(n)} \) is picked up from the interval \( I_r^{(n)} = \{ \xi_r^{(n)}(n), \xi_r^{(n)}(n+1) \} \), whose volume is \( \sqrt{\frac{d}{n}} \). Therefore we regard the sum on (4.14) as a Riemann sum, and the sum converges to the integral

\[
\int_{\mathcal{S}_d} e^{-2(|y_1| + \cdots + |y_d|)} P(y_1, \ldots, y_d) dy_1 \cdots dy_{d-1},
\]

where the integral runs over \((y_1, \ldots, y_{d-1}) \in \mathbb{R}^{d-1}\) such that \((y_1, \ldots, y_d) \in \mathcal{S}_d\) for \( y_d := -(y_1 + \cdots + y_{d-1}) \). We can apply the dominated convergence theorem: by (4.12),

\[
\frac{\alpha^{2n}(2\pi)^d \left( \frac{n}{d} \right)^{2n} e^{d-n \frac{d-1}{2}}}{\Gamma(1/\alpha) d e^{2n}} C_{n,d}(\alpha)
\]

\[= \sum_{\lambda_1 \geq \cdots \geq \lambda_{d-1} \geq \lambda_d = 0} \left( \frac{d}{n} \right)^{d-1} c^{(\alpha)} \left( \frac{n}{d} + \xi^{(n)}_1 \sqrt{\frac{n}{d}} \cdots + \xi^{(n)}_d \sqrt{\frac{n}{d}} \right) \frac{\alpha^{2n}(2\pi)^d \left( \frac{n}{d} \right)^{2n} e^{d-n \frac{d-1}{2}}}{\Gamma(1/\alpha) d e^{2n}}
\]

\[
eq \lim_{n \to \infty} \int_{\mathcal{S}_d} e^{-2(y_1^2 + \cdots + y_d^2)} \prod_{1 \leq i < j \leq d} (y_i - y_j)^{2/\alpha} dy_1 \cdots dy_{d-1}.
\]

Changing variables as \( y_j = \alpha^{-1/2} x_j \), we obtain the lemma.

Our goal is to prove the following equation: for any \( 1 \leq k \leq d \) and any \( h_1, \ldots, h_k \in \mathbb{R} \),

\[
\lim_{n \to \infty} \frac{1}{C_{n,d}(\alpha)} \sum_{\lambda \in P_n(d)} \frac{1}{c_\lambda(\alpha)c'_\lambda(\alpha)} \frac{1}{\sqrt{\alpha^{(n)}_{\lambda_i} \leq h_i \ (1 \leq i \leq k)}}
\]

\[= \frac{1}{Z_d(2/\alpha)} \int_{x_{d-1} = -(x_1 + \cdots + x_{d-1})} e^{-\frac{1}{\alpha} (x_1^2 + \cdots + x_d^2)} \prod_{1 \leq i < j \leq d} (x_i - x_j)^{2/\alpha} dx_1 \cdots dx_{d-1}.
\]

Here the integral runs over \((x_1, \ldots, x_{d-1}) \in \mathbb{R}^{d-1}\) satisfying \( x_1 \geq \cdots \geq x_{d-1} \geq x_d \) and \( x_i \leq h_i \ (1 \leq i \leq k) \) for \( x_d := -(x_1 + \cdots + x_{d-1}) \).

The rest of the proof of the theorem is similar to the proof of Lemma 4.4. We write as

\[
\frac{1}{C_{n,d}(\alpha)} \sum_{\lambda \in P_n(d)} \frac{1}{c_\lambda(\alpha)c'_\lambda(\alpha)} \frac{1}{\sqrt{\alpha^{(n)}_{\lambda_i} \leq h_i \ (1 \leq i \leq k)}}
\]

\[= \frac{1}{C_{n,d}(\alpha)} \frac{\Gamma(1/\alpha) d e^{2n}}{\alpha^{2n}(2\pi)^d \left( \frac{n}{d} \right)^{2n} e^{d-n \frac{d-1}{2}}}
\]

\[\times \sum_{\lambda \in P_n(d)} \left( \frac{d}{n} \right)^{d-1} c^{(\alpha)} \left( \frac{n}{d} + \xi^{(n)}_1 \sqrt{\frac{n}{d}} \cdots + \xi^{(n)}_d \sqrt{\frac{n}{d}} \right) \frac{\alpha^{2n}(2\pi)^d \left( \frac{n}{d} \right)^{2n} e^{d-n \frac{d-1}{2}}}{\Gamma(1/\alpha) d e^{2n}}.
\]
Using (4.12) and Lemma 4.4 as \( n \to \infty \), it converges to
\[
\frac{\alpha^{d(d-1)/2} d^{-1/2}}{Z_d(2/\alpha)} \int_{y_d:=(y_1,\ldots,y_{d-1})} e^{-\frac{1}{\alpha}(y_1^2+\cdots+y_d^2)} \prod_{1\leq i<j\leq d} (y_i - y_j)^{2/\alpha} dy_1 \cdots dy_{d-1} = \frac{1}{Z_d(2/\alpha)} \int_{x_d:=(x_1,\ldots,x_{d-1}) \in \mathbb{R}^{d-1}} e^{-\frac{1}{\alpha}(x_1^2+\cdots+x_d^2)} \prod_{1\leq i<j\leq d} (x_i - x_j)^{2/\alpha} dx_1 \cdots dx_{d-1}. 
\]

Thus we have proved Theorem 2.1.

5 A short proof of Regev’s asymptotic theorem

Applying the technique used in the previous section, we give a simple proof of the following asymptotic theorem by Regev \cite{Re}.

Let \( f^\lambda \) be the degree of the irreducible representation of the symmetric group \( \mathfrak{S}_|\lambda| \) associated with \( \lambda \). Equivalently, \( f^\lambda \) is the number of standard Young tableaux of shape \( \lambda \).

**Theorem 5.1** (Regev). Let a positive real number \( \beta \) and a positive integer \( d \) be fixed. As \( n \to \infty \),
\[
\sum_{\lambda \in \mathcal{P}_n(d)} (f^\lambda)^\beta \sim \left( (2\pi)^{d/2} n^{d^2/2} n^{-(d-1)(d+2)/4} \right)^\beta n^{d-1/2} Z_d'(\beta),
\]
where
\[
Z_d'(\beta) = \int_{\mathbb{R}^d} e^{-\frac{d\beta}{2}(x_1^2+\cdots+x_d^2)} \prod_{1\leq i<j\leq d} (x_i - x_j)^{\beta} dx_1 \cdots dx_{d-1}.
\]

**Proof.** Recall the hook formula (2.3):
\[
f^\lambda = \frac{n!}{c_\lambda(1)} = n! \prod_{1 \leq i < j \leq d} (\lambda_i - \lambda_j + j - i) \prod_{i=1}^d \frac{1}{\Gamma(\lambda_i + d - i + 1)}.
\]
Replacing each \( \lambda_i \) by \( r_i \) in this identity, we can define the value \( f^{(r_1,\ldots,r_d)} \) for all non-negative real numbers \( r_1, \ldots, r_d \) such that \( r_1 \geq \cdots \geq r_d \geq 0 \) and \( r_1 + \cdots + r_d = n \). Applying Lemma 4.3, we see that for each \( (y_1,\ldots,y_d) \in \mathbb{R}^d \), putting \( r_i = \frac{n}{d} + y_i \sqrt{\frac{d}{2n}} \) (\( 1 \leq i \leq d \)),
\[
\lim_{n \to \infty} \frac{\left( \frac{n}{d} \right)^{n+d^2/2}}{n! e^n} f^{(r_1,\ldots,r_d)} = \prod_{1 \leq i < j \leq d} (y_i - y_j) \cdot \frac{d}{\sqrt{2\pi}} \cdot \prod_{i=1}^d e^{-\frac{1}{2} y_i^2}.
\]
Furthermore, by the Stirling formula \( n! \sim \sqrt{2\pi n^{n+\frac{1}{2}}} e^{-n} \), we have
\[
\lim_{n \to \infty} (2\pi)^{d-1} d^{-n-d^2/2} n^{d^2/4 - d/2} f^{(r_1,\ldots,r_d)} = \prod_{1 \leq i < j \leq d} (y_i - y_j) \cdot \prod_{i=1}^d e^{-\frac{1}{2} y_i^2}.
\]
On the other hand, as in the proof of (4.8), we can prove that there exists a polynomial $P$ such that
\[ d^{-n - \frac{d^2 + d}{4} n^{\frac{d+2}{4} - \frac{d}{2}}} f(r_1, \ldots, r_d) < P(y_1, \ldots, y_d)e^{-|y_1| - \cdots - |y_d|} \]
for all $n$ and $y_1, \ldots, y_d$.

Consider
\[ \left(\frac{2\pi}{d-1}\right)^{\frac{d-1}{2}} d^{-n - \frac{d^2 + d}{4} n^{\frac{d+2}{4} - \frac{d}{2}}} \sum_{\lambda \in \mathcal{P}_n(d)} (f^{\lambda})^\beta. \]

As in the proof of Lemma 4.4, we can apply the dominated convergence theorem with a dominated function of the form
\[ P(y_1, \ldots, y_d) e^{-\beta(|y_1| + \cdots + |y_d|)}. \]

Then
\[ \lim_{n \to \infty} \left(\frac{2\pi}{d-1}\right)^{\frac{d-1}{2}} d^{-n - \frac{d^2 + d}{4} n^{\frac{d+2}{4} - \frac{d}{2}}} \sum_{\lambda \in \mathcal{P}_n(d)} (f^{\lambda})^\beta = \int_{S_d} e^{-\beta(y_1^2 + \cdots + y_d^2)} \prod_{1 \leq i < j \leq d} (y_i - y_j)^\beta \, dy_1 \cdots dy_{d-1} = Z_d(\beta). \]

It is easy to see that $Z_d(\beta) = d^{d(d-1)\beta + \frac{d+1}{2}} Z'_d(\beta)$. Thus, we have proved the theorem.

Using Lemma 4.4 and the Stirling formula, we obtain the following.

**Proposition 5.2.** As $n \to \infty$,
\[ \sum_{\lambda \in \mathcal{P}_n(d)} \frac{n!}{c_\lambda(\alpha)} \frac{n!}{c'_\lambda(\alpha)} \sim \frac{\Gamma(1/\alpha)^d d^{2n + \frac{d^2}{2}}}{(2\pi)^{d-1} \alpha^{2n + 2^2 - d + \frac{d-1}{2}} n^{d^2 + d - \frac{d+1}{2}}} Z'_d(2/\alpha). \]

This proposition may be seen as a Jack analogue (of the $\beta = 2$ case) of Theorem 5.1.
