Role of DNA Methylation in the Regulation of Lipogenic Glycerol-3-Phosphate Acyltransferase 1 Gene Expression in the Mouse Neonatal Liver

Tatsuya Ehara,1,2 Yasutomi Kamei,1,3 Mayumi Takahashi,1 Xunmei Yuan,1 Sayaka Kanai,1 Erina Tamura,1 Miyako Tanaka,1,3 Tomomi Yamazaki,4 Shinji Miura,4 Osamu Ezaki,4 Tatsuya Ehara,1,2 Yasutomi Kamei,1,3 Mayumi Takahashi,1 Xunmei Yuan,1 Sayaka Kanai,1 Erina Tamura,1 Miyako Tanaka,1,3 Tomomi Yamazaki,4 Shinji Miura,4 Osamu Ezaki,4 Takayoshi Suganami,1 Masaki Okano,5 and Yoshihiro Ogawa1,6,7

The liver is a major organ of lipid metabolism, which is markedly changed in response to physiological nutritional demand; however, the regulation of hepatic lipogenic gene expression in early life is largely unknown. In this study, we show that expression of glycerol-3-phosphate acyltransferase 1 (GPAT1; Gpam), a rate-limiting enzyme of triglyceride biosynthesis, is regulated in the mouse liver by DNA methylation, an epigenetic modification involved in the regulation of a diverse range of biological processes in mammals. In the neonatal liver, DNA methylation of the Gpam promoter, which is likely to be induced by Dnmt3b, inhibited recruitment of the lipogenic transcription factor sterol regulatory element–binding protein-1c (SREBP-1c), whereas in the adult, decreased DNA methylation resulted in active chromatin conformation, allowing recruitment of SREBP-1c. Maternal overnutrition causes decreased Gpam promoter methylation with increased GPAT1 expression and triglyceride content in the pup liver, suggesting that environmental factors such as nutritional conditions can affect DNA methylation in the liver. This study is the first detailed analysis of the DNA-methylation–dependent regulation of the triglyceride biosynthesis gene Gpam, thereby providing new insight into the molecular mechanism underlying the epigenetic regulation of metabolic genes and thus metabolic diseases.

The liver is a major organ of lipid metabolism, which is physiologically changed during organ maturation (1,2). The rate of hepatic de novo lipogenesis (i.e., triglyceride [TG] biosynthesis) is very low during the suckling period, when fat intake is high from milk, but it rises with the onset of weaning, when glucose is used as a source of energy (1). Thus, hepatic gene expression may change markedly before and after weaning, which could be regulated in response to nutritional demand.

TG is the major storage form of energy in animals. TG biosynthesis begins with the acylation of glycerol-3-phosphate by glycerol-3-phosphate acyltransferase 1 (GPAT1; Gpam) to form lysophosphatidic acid; this is the rate-limiting step in the hepatic TG biosynthesis pathway (3). In the acylation process, fatty acids produced by stearoyl CoA desaturase 1 (SCD1; Scd1) and fatty acid synthase (FAS; Fasn) are used as acyl donors. Among the lipogenic enzymes, GPAT1 plays an important role in the regulation of hepatic TG biosynthesis (4,5). The lipogenic genes such as Gpam, SCD1, and FASN are activated by sterol regulatory element–binding protein-1c (SREBP-1c), which is a transcription factor and master regulator of lipogenesis. Indeed, their promoter regions contain the SREBP-responsive elements (SREs) (6–8). Aberrant lipogenic gene regulation can contribute to fatty liver, which is associated with obesity, type 2 diabetes, and insulin resistance (9). However, the molecular mechanism involved in the regulation of lipogenic genes during early life remains largely unclear.

The methylation of cytosine residues in DNA is a major epigenetic modification, and its role is well studied in organ development and cell differentiation (10–12). In most instances, DNA methylation of the promoter regions causes suppression of gene expression (13). In mammals, three CpG DNA methyltransferases (Dnmt1—Dnmt1, Dnmt3b, and Dnmt3a—coordinate regulation of DNA methylation in the genome. Dnmt1 promotes DNA methylation after DNA replication and plays a major role in the maintenance of methylation (14). Dnmt3a and Dnmt3b are required for the initiation of de novo DNA methylation (15).

DNA methylation may be affected by environmental factors, thereby regulating a variety of metabolic processes and diseases (15–18). Although the fetal and neonatal periods, which are highly plastic to environmental changes, should be under the epigenetic control, the role of DNA methylation in early life has not fully been addressed. This study is the first demonstration that the DNA methylation status of the Gpam promoter and its mRNA expression are inversely correlated during mouse liver maturation. This study highlights the role of DNA methylation in the regulation of lipogenic genes, thereby providing new insight into the molecular mechanism underlying epigenetic regulation of metabolic diseases.

RESEARCH DESIGN AND METHODS

Animals and the experiment with HF/HS diet-fed dams. Pregnant female C57BL/6 mice were obtained from Japan SLC (Hamamatsu, Japan). The mice were fed ad libitum a standard rodent chow, CRF1 (Charles River Japan, Tokyo, Japan). Offspring at the indicated ages were used for tissue sampling. They

were weaned at 25 days of age and thereafter fed CRF1 throughout the experiment.

The experiment with HF/HIS diet-fed dams was performed as follows. Six-week-old male and female C57BL/6j mice (Japan SLC) were crossed, and pregnancy was confirmed by treatment with a progesterone. Two weeks later, nuclear DNA of tail was isolated, and throughout the experiment, dams were fed ad libitum either CRF1 (standard) or HF/HIS diet (D12070B; Research Diets, New Brunswick, NJ). Schematic experimental design is shown in Supplementary Fig. 1. Five-day-old offspring were used for analysis. All animal experiments were approved by Institutional Animal Care and Use Committee of Tokyo Medical and Dental University (approval identification number 0000041).

Quantitative real-time PCR analysis. Gene expression levels were measured as described (19). The primers used are shown in Table 1.

Western blot analysis. The nuclear fraction of cell lysate was prepared using a ProteoJET Cytoplasmic and Nuclear Protein Extraction Kit (Fermentas, Glen Burnie, MD). Mitochondrial fraction of the liver was prepared as described (4). Western blot analysis was performed as described previously (19). Anti-GPAT1 (sc-161674; Santa Cruz Biotechnology; Santa Cruz, CA), anti-SCD1 (ab19862; Abcam, Cambridge, MA), anti-FAS (sc-48357; Santa Cruz Biotechnology), anti–SREBP-1 (ab12350; Abcam), anti-CoxIV (ab14774; Abcam), anti–α-tubulin (T9026; Sigma-Aldrich, St. Louis, MO), anti-Lamin a/c (sc-20681; Santa Cruz Biotechnology), anti-Dnmt3b (IMG184A; Imgenex, San Diego, CA), and histone H1 (sc-10806; Santa Cruz Biotechnology) was used as the primary antibody.

Bisulfite conversion and methylation analysis. Sodium bisulfite treatment of genomic DNA was performed with a BisuFast DNA modification kit (Toyobo, Tokyo, Japan) according to the manufacture’s instructions. Sequential PCR amplification of the fragments of interest was performed using specific primers (Supplementary Table 2). The PCR profile was as described in Supplementary Table 2. The amplified fragments were ligated into the vector pGEM-T-Easy (Promega KK, Tokyo, Japan) and sequenced. At least 16 bacterial colonies were picked up per PCR amplification. A web-based tool, quantification tool for quantitative PCR analysis, was used for bisulfite sequence analysis of CpG methylation (http://quma.cbh.riken.jp/) (20).

Quantification of DNA methylation of the Gpam promoter. DNA digestion with methylation-sensitive HpaII and quantitative real-time PCR were performed as described previously (21), with the following primers: forward primer 5'-CCCTAAAACGGTCCGGAGA-3' and reverse primer 5'-CATGACCAATGAGTCTCGAGA-3'. The forward primer contains the HpaII site of Gpam promoter (underlined).

Primary culture of mouse hepatocytes. Primary hepatocytes were isolated as described previously (22,23).

Preparation of recombinant adenosinevirus. The full-length mouse Dnm3b1 cDNA was subcloned into the pShuttle vector provided in the BD Adeno-X Expression System (BD Biosciences, Franklin Lakes, NJ). BD Adeno-X enhanced green fluorescent protein (GFP) was used as a control (Ad-GFP; BD Biosciences). Ad-SREBP-1c (active-nuclear form) (24) was kindly provided from Dr. Hitoshi Shimano (Tsukuba University). Each recombinant adenosinevirus (Ad-Dnm3b, Ad-SREBP-1c, or Ad-GFP) was added to the medium of primary cultured cells at an moi of 10. The Ad-Dnm3b or Ad-GFP was added to the medium of primary cultured hepatocytes to examine the effect of SREBP-1c on Gpam promoter activation. After a 30-min preincubation period, liver strips were transferred to vials containing 0.5 μM of 1-[14C]palmitate (GE Healthcare Life Sciences, Buckinghamshire, U.K.) for 60 min. For primary hepatocytes, cells were incubated with 1-[14C]palmitate in medium for 6 h. From the liver or cells, lipids were extracted with chloroform/methanol (2:1) and resolved by thin-layer chromatography (hexane/ethyl ether/acetic acid = 60:40:3) followed by phosphoimaging detection.

Transfection and luciferase assay with methylated plasmids. A luciferase gene construct containing the Gpam promoter fragment (from −489 to +79, taking the first nucleotide of exon 1 as +1) was prepared. For in vitro DNA methylation analysis, the construct was digested with Asp718/XhoII, and a fragment containing the Gpam promoter (−489 to +79) was purified, which was followed by treatment with SsoI (CpG methylase) as described previously (17). Methylating analysis was confirmed by digestion with a methylation-sensitive restriction enzyme, HpaII. The luciferase assay was performed as described in (19,24).

Chromatin immunoprecipitation analysis. Chromatin immunoprecipitation (ChIP) was performed using an assay kit (Upstate, Temecula, CA) (25). The lysate was incubated with Dynabeads protein G-conjugated (Life Technologies, Carlsbad, CA) anti–SREBP-1c (sc-8084X; Santa Cruz Biotechnology) and anti-Dnmt3a (ab-20701; Santa Cruz Biotechnology), anti-Dnmt3a (ab-2859; Abcam), anti-Dnmt3b (ab-2851; Abcam), anti-trimethyl-histone H3 (Lys4) (807-473; Upstate), anti-acetyl-histone H3 (Lys9) (806-011; Millipore, Temecula, CA), anti–dimethyl-histone H3 (Lys9) (97693; Cell Signaling Technology, Danvers, MA) or rabbit normal IgG (sc-2027; Santa Cruz Biotechnology). The ChIP-enriched DNA samples were analyzed by quantitative PCR. PCR primers were designed to locate SREs of the Gpam or Scd1 promoter (Supplementary Table 3).

Liver TG analysis. The liver TG levels were measured by enzymatic colorimetry as described (19).

Statistical analysis. Statistical analysis was performed using Student t test and ANOVA followed by Scheffe test. Data were expressed as the mean ± SE. A P value of <0.05 was considered statistically significant.

RESULTS

Lipogenic gene and SREBP-1c mRNA expression in the neonatal and adult livers. We examined lipogenic gene expression in the neonatal and adult livers before and after weaning. The GPAT1 mRNA was only slightly expressed in the neonatal liver (days 0, 5, and 9), but markedly increased (−40-fold) in the adult liver (10 weeks of age). Similar to GPAT1, both SCD1 and FAS mRNA levels, as well as protein levels of GPAT1, SCD1, and FAS, and GPAT-mediated TG/diacylglycerol (DG) biosynthesis were increased in the adult liver relative to the neonatal liver (Fig. 1A and Supplementary Fig. 2). There is a GPAT1 splicing-variant (GPAT1-variant) with an alternative first noncoding exon (GenBank accession number: NM_008149) using an alternative promoter that is −30 kb downstream from the Gpam promoter containing SREs, thus producing the identical coding GPAT1 protein. In this study, its mRNA expression showed a relatively small increase (approximately threefold) from neonates (day 0) to adults (Fig. 1A).

SREBP-1c mRNA was weakly expressed in the neonatal liver (day 0) and increased markedly (−100-fold) in the adult liver (10 weeks of age). At day 9, approximately half the level seen in the adults was observed (Fig. 1A). SREBP-1c protein level was very low on day 0 and modestly and markedly increased on day 9 and in adults, respectively (Fig. 1A). Namely, on day 9, SREBP-1c was expressed but its target genes were not; they showed delayed expression than SREBP-1c, suggesting that the activity of SREBP-1c is regulated posttranslationally.

DNA methylation of lipogenic gene promoters in neonatal and adult livers. The Gpam promoter region contains three SREs (Fig. 1B) (6). Bisulfite analysis revealed high DNA methylation levels of the Gpam promoter containing SREs in the neonatal liver (day 0) (Fig. 1C). By contrast, less DNA methylation levels were observed in the adult liver (Fig. 1C). We also confirmed the differential DNA methylation of the Gpam promoter in the neonatal and adult livers, based upon digestion with a methylation-sensitive enzyme, HpaII, for which the recognition site locates between the first and second SREs (Fig. 1B), and a subsequent quantitative real-time PCR analysis. Consistent with the data of bisulfite analysis, DNA methylation levels were high in the neonatal liver (day 0 and 5; −60%, day 9; −55%) relative to the adult liver (−15%) (Fig. 1D). By contrast, appreciable DNA methylation of the Scd1 and Fasn promoters, containing SREs, was not observed in both the neonatal (day 0) and adult (10 weeks of age) livers (Fig. 1E).

In a CpG island of the alternative promoter of the Gpam, there was also no significant DNA methylation in the neonatal (day 0) and adult (10 weeks of age) livers (Fig. 1E). In contrast, DNA methylation levels were high in the repetitive element of intracisternal A particle (IAP) (26), one of the markers of global DNA methylation, in both the neonatal and adult livers (Fig. 1E). It is therefore likely that DNA methylation differs in certain regions of the genome between neonatal and adult livers.

DNA methylation of the Gpam promoter in the adult skeletal muscle. In contrast to the liver, high DNA methylation levels in the Gpam promoter were observed in

DIABETES diabetes.diabetesjournals.org
FIG. 1. Lipogenic gene expression and DNA methylation in the neonatal and adult mice livers. A: Relative lipogenic gene and SREBP-1c mRNA levels in the neonatal (days after birth: 0, 5, and 9) and adult livers (after weaning, 10 weeks of age), examined by quantitative real-time PCR. Values for day 0 were set at 1. Western blot analysis of GPAT1, SCD1, FAS, and nuclear form of SREBP-1 (nSREBP1) in neonatal (days 0 and 9) and adult livers (10 weeks of age). For GPAT1, mitochondrial fraction was used. For FAS/SCD1 and SREBP-1, cytoplasmic and nuclear fractions were used, respectively. α-Tubulin and Lamin A/C are cytoplasmic and nuclear markers, respectively, used for loading controls. B: Schematic representation of the Gpam promoter region. The Gpam promoter contains three SREs (−186 to −178, −170 to −161, and −64 to −55, transcription start site counted as +1). Each circle denotes a CpG site, numbered 1–9. The HpaII site is indicated (arrow). Position of PCR primers for bisulfite PCR analysis (BS) and ChIP analysis are indicated. C: Bisulfite analysis of the Gpam promoter. PCR primers used in bisulfite analysis for the Gpam promoter are shown in B. Filled circles are methylated and open circles are unmethylated CpGs. The numbers beneath are as shown in B. The left panel is a neonatal liver sample (day 0), and the right panel is an adult liver sample (10 weeks of age). Representative results of three independent animals of each group with similar results are shown. D: DNA methylation of the Gpam promoter, estimated by HpaII digestion followed by quantitative real-time PCR. Genomic DNA treated with BamHI alone was prepared as an uncut control (i.e., a fully methylated control [100%]) and diluted as a standard dilution series. *P < 0.05, ***P < 0.001 compared with D0 sample; n = 3. E: Bisulfite analysis of the Scd1 and Fasn promoters and the alternative Gpam promoter, containing CpG island, and IAP in the neonatal and adult liver. Representative results of three independent animals of each group with similar results are shown. F: Bisulfite analysis and quantitative real-time PCR mRNA analysis of the Gpam promoter in the adult skeletal muscle (10 weeks of age). Values for the liver were set at 1. n = 3. G: Bisulfite analysis of the alternative Gpam promoter in the adult skeletal muscle and relative GPAT1-variant mRNA levels in the adult liver and skeletal muscle. n = 3. CoxIV, cytochrome oxidase IV, a mitochondrial marker.
the skeletal muscle of adult mice, where its mRNA expression was very low (Fig. 1F). DNA methylation levels of the alternative Gpam promoter were low in the skeletal muscle and liver, and GPAT1-variant expression levels were similar between the skeletal muscle and liver (Fig. 1G). These observations, taken together, suggest that DNA methylation of the Gpam promoter, containing SREs, and its mRNA expression are inversely correlated in the skeletal muscle.

**DNA methylation of the Gpam promoter in primary culture of neonatal mouse hepatocytes.** We next examined DNA methylation of the Gpam promoter in primary culture of neonatal mouse hepatocytes. In this study, the gene expression of albumin, a marker of mature hepatocytes, increased during the course of culture, suggesting the maturation of primary hepatocytes (Fig. 2A). The DNA methylation levels of the Gpam promoter was high at 0 h but gradually decreased at 48 and 96 h, and GPAT1 mRNA levels were low at 0 h and increased at 48 and 96 h (Fig. 2B). By contrast, DNA methylation levels of IAP remained high at both 0 and 96 h (Fig. 2B), suggesting that decreased methylation is not likely due to total demethylation of the whole genome. These observations also suggest an inverse correlation between DNA methylation of the Gpam promoter and its mRNA expression in primary culture of neonatal mouse hepatocytes.

**Reporter activity from the Gpam promoter with in vitro DNA methylation.** In an in vitro reporter assay, we examined whether DNA methylation of the Gpam promoter affects the SREBP-1c-induced transcriptional activity. Cotransfection of the Gpam promoter-Luc without DNA methylation and SREBP-1c expression plasmid in HEK293 cells caused increased reporter activity from the Gpam promoter (Fig. 2C). By contrast, upon methylation of the Gpam promoter, Luc activity was not increased above the basal level even in the presence of the SREBP-1c expression plasmid (Fig. 2C).

**Adenovirus-mediated SREBP-1c overexpression and ChIP analysis of the Gpam promoter in neonatal and adult primary hepatocytes.** To address whether DNA methylation of the Gpam promoter is critical for SREBP-1c-dependent GPAT1 expression, we overexpressed SREBP-1c in neonatal (high DNA methylation) and adult (low DNA methylation levels in the Gpam promoter) primary hepatocytes through the adenoviral technique. We observed similarly high expression of nuclear form of SREBP-1c protein in neonatal and adult primary hepatocytes (Fig. 2D). In this experiment, we observed less expression of GPAT1 with lower recruitment of SREBP-1 to the Gpam promoter in the neonatal primary hepatocytes relative to adult primary hepatocytes (Fig. 2D). The data indicated that GPAT1 expression is low even in the presence of considerable SREBP-1c expression, suggesting that DNA methylation of the Gpam promoter is critical for SREBP-1c-dependent GPAT1 expression.

**ChIP analysis of the Gpam promoter in neonatal and adult liver.** Dnmt1, -3a, and -3b mRNA expression was detected in the neonatal and adult livers, although the DNA METHYLATION OF THE Gpam PROMOTER IN LIVER...
hepatic Dnmt1 mRNA levels were lower in the adult liver than in the neonatal liver (Fig. 3A). Therefore, we performed ChIP analysis to compare the recruitment of SREBP-1 and Dnmts to the Gpam promoter between the neonatal and adult livers. In this study, SREBP-1 was not recruited to the Gpam promoter in the neonatal liver (day 0 after birth), although it was clearly recruited in the adult liver (Fig. 3B). Importantly, Dnmt3b was strongly recruited to the Gpam promoter in the neonatal liver, but not in the adult liver (Fig. 3B). Dnmt3a was also recruited, although weakly, to the Gpam promoter in the neonatal liver, but not in the adult liver (Fig. 3B). We also found that levels of histone H3 lysine-4-trimethylation (H3K4me3) and lysine-9-acetylation (H3K9Ac), two transcriptionally active histone codes, are increased and those of the repressive histone H3 lysine-9-di-methylation (H3K9me2) are decreased at the Gpam promoter in the adult liver relative to the neonatal liver (Fig. 3B). The recruitment of Dnmt3a and Dnmt3b to the Scd1 promoter did not differ significantly between the neonatal and adult livers (Fig. 3C). In this study, we observed that the recruitment of SREBP-1 and level of H3K9Ac are increased and that of H3K9me2 is decreased at the Scd1 promoter in the adult liver relative to the neonatal liver (Fig. 3C).

**DNA methylation of the Gpam promoter and GPAT-mediated TG/DG synthesis in primary hepatocytes with Dnmt3b overexpression.** With adenoviral transduction of Dnmt3b, which was strongly recruited to the Gpam promoter.

---

**FIG. 3.** Recruitment of SREBP-1c and Dnmts to the Gpam and Scd1 promoters containing SREs, with changes in histone modification. A: Relative Dnmt3a mRNA levels in the neonatal (days after birth: 0, 5, and 9) and adult livers (10 weeks of age) examined by quantitative real-time PCR. Values for day 0 were set at 1. n = 3 to 4. B: ChIP analysis. Neonatal (day 0) and adult (10 weeks) livers were used for ChIP analysis with the indicated antibodies. Amplified PCR primers are as shown in Fig. 1B. The top left panel is a representative gel electrophoresis photo. Input is a PCR product from the aliquot of liver lysate before immunoprecipitation (IP). The graphs demonstrate quantitative PCR analysis. The graph of Dnmt1 is not shown because signals from the neonatal and adult livers are lower than the negative control IgG signals. C: ChIP analysis in the Scd1 promoter in the samples used in B. Values of adult sample are set at 1. *P < 0.05, **P < 0.01, ***P < 0.001, n = 3 to 4.
in the neonatal liver (Fig. 3B), we next examined DNA methylation of the *Gpam* promoter, its mRNA expression, and TG/DG synthesis in primary hepatocytes, which were obtained from adult mice with low DNA methylation levels of the *Gpam* promoter. In this study, we confirmed Dnmt3b overexpression causes significant Dnmt3b protein expression (Fig. 4A). We found increased DNA methylation of the *Gpam* promoter (Fig. 4B), but not *Scd1* and *Fasn* promoters (Fig. 4C), in Dnmt3b-expressing hepatocytes relative to control GFP-expressing hepatocytes. The GPAT1 mRNA levels were markedly lower in hepatocytes with Dnmt3b overexpression than those with control GFP (Fig. 4D). In the *Gpam* promoter (Fig. 4E), but not the *Scd1* promoter (Fig. 4F), SREBP-1 was less recruited in Dnmt3b-expressing hepatocytes than in control GFP-expressing hepatocytes. In addition, TG/DG synthesis and TG contents were lower in Dnmt3b-expressing hepatocytes than in GFP-expressing hepatocytes (Fig. 4G). These data suggest that increased DNA methylation suppresses SREBP-1 recruitment in the *Gpam* promoter, decreased GPAT1 expression, and TG/DG synthesis.

**DNA methylation of the *Gpam* promoter in the neonatal offspring liver of the high-fat/high-sucrose diet-fed dams.** We next examined whether the observed DNA methylation of the *Gpam* promoter is affected by environmental factors in vivo. A high-fat or high-calorie diet fed to female animals during gestation and lactation has been reported to increase lipogenic gene expression and TG levels in the liver of offspring (27). In this study, we fed a high-calorie, lipogenic high-fat/high-sucrose (HF/HS) diet to dams and examined DNA methylation of the *Gpam* promoter in the offspring. In pups of the HF/HS diet-fed dams, DNA methylation levels of the *Gpam* promoter were lower, and GPAT1 mRNA levels and SREBP-1 recruitment, but not SREBP-1c mRNA levels, were higher than those in the pups of standard diet-fed dams (Fig. 5A–D). In this study, hepatic TG levels increased in the pups of the HF/HS diet-fed dams relative to those of the standard diet-fed dams (Fig. 5E).

**DISCUSSION**

The DNA methylation status has been considered to be relatively stable except during embryogenesis and carcinogenesis. However, recent studies showed that DNA methylation can be modulated in normal tissues even after birth (28). In this study, we show that expression of *Gpam*, which encodes a rate-limiting enzyme for TG biosynthesis, increases in the liver during weaning in response to the physiologic demand of TG biosynthesis. This may be related to the dynamic change in the DNA methylation status of the *Gpam* promoter during liver maturation. In the neonatal liver, the *Gpam* promoter region, containing three SREs, shows high DNA methylation levels with low *Gpam* expression, whereas in the adult liver, it shows low DNA methylation levels with high *Gpam* expression. Importantly, SREBP-1c is recruited to the promoter in the adult liver but not in the neonatal liver. In this study, in vitro analysis revealed that

![FIG. 4. DNA methylation level of the *Gpam* promoter and GPAT-mediated TG/DG synthesis in the adult primary hepatocytes overexpressing Dnmt3b. A: Protein expression levels of Dnmt3b in adult primary hepatocytes overexpressing Dnmt3b and control GFP. Endogenous Dnmt3b protein expression is known to be high in early embryo and embryonic stem cells, but very low in adult tissues (33) and was not detected in this experiment using adult primary hepatocyte samples. B: DNA methylation level of the *Gpam* promoter in adult primary hepatocytes overexpressing Dnmt3b and control GFP. Results of two independent dishes from each group are shown. C: DNA methylation level of the *Scd1* and *Fasn* promoters. D: Expression of GPAT1 mRNA levels and recruitment of SREBP-1 to the *Gpam* (E) and *Scd1* (F) promoters. Values of GFP cells are set at 1. G: TG/DG synthesis levels and TG contents. **P < 0.01, ***P < 0.001. n = 3.](image-url)
DNA methylation of the *Gpam* promoter can suppress the SREBP-1c-mediated transcriptional activation. Less SREBP-1 recruitment in the *Gpam* promoter in Dnmt3b-overexpressing hepatocytes suggests that DNA methylation of the *Gpam* promoter inhibited SREBP-1c recruitment. These observations, taken together, suggest the role of DNA methylation in the suppressed *Gpam* expression in the neonatal liver even in the presence of SREBP-1c. This above discussion is consistent with a previous observation that the extent of hepatic de novo lipogenesis in the neonatal liver is lower than that in the adult liver (1). Consistent with the decreased DNA methylation, transcriptionally active H3K4me3 and H3K9Ac are increased, whereas repressive H3K9me2 is decreased at the *Gpam* promoter in the adult liver. It is conceivable that in the neonatal liver, DNA methylation of the *Gpam* promoter plays roles in the formation and/or maintenance of transcriptionally repressive chromatin conformation, thereby inhibiting the recruitment of SREBP-1c. In contrast, in the adult liver, decreased DNA methylation and increased active histone modifications may lead to the recruitment of SREBP-1c to the *Gpam* promoter.

The mechanism underlying the altered DNA methylation of the genome has not been thoroughly investigated. In this study, we found that Dnmt3b, which is implicated in de novo DNA methylation, is strongly recruited to the *Gpam* promoter in the neonatal liver but not in the adult liver. Dnmt3b overexpression markedly increases DNA methylation levels of the *Gpam* promoter in primary adult hepatocytes. Dnmt3b plays important roles in embryogenesis (10). It has been recently reported to be involved in colon cancer (29) and hormonal gene regulation in renal tubular cells (30). Therefore, it is likely that the decreased recruitment of Dnmt3b plays a role in the decreased DNA methylation of the *Gpam* promoter, and additional mechanism(s) for DNA demethylation may be involved in the process.

The H3K4 methylation level is reported to be reciprocal with the DNA methylation level, and H3K4me2/3 and DNA methylation occur mutually exclusively (11,31). In the region of H3K4me2/3, the DNA methylation levels are generally low. Alternatively, Dnmt3 may preferentially bind to genomic DNA without H3K4 methylation. In this study, the H3K4me3 level in the *Gpam* promoter was low in the neonatal liver and high in adult liver, whereas the H3K4me3 level in the *Scd1* promoter was similar in neonatal and adult livers. Thus, it is possible that histone modification is involved in the regulation of specificity of DNA methylation in *Gpam* and *Scd1* promoters. In addition, because GPAT1 contributes to the transfer of fatty acid to glycerol, whereas SCD1 and FAS are involved in fatty acid biosynthesis (3), the differential positioning of GPAT1, SCD1, and FAS in the TG biosynthesis pathway may explain the different mechanisms of their gene expression. Further studies are required to elucidate how *Sed1* and *Fasn* transcription is regulated in the neonatal liver.

In this study, we also found that GPAT1 mRNA levels are much lower in the adult skeletal muscle than those in the adult liver, although SREBP-1c is highly expressed in
both tissues (19). This is consistent with a previous report that the GPAT1 enzymatic activity in the skeletal muscle is much lower than that in the liver (32). The low expression of Gpam in the adult skeletal muscle may be because the high DNA methylation of the Gpam promoter suppresses the SREBP-1c–mediated transcriptional activation. Therefore, it is conceivable that DNA methylation of the Gpam promoter is involved in the SREBP-1c–dependent tissue-specific regulation of Gpam expression. In contrast, the expression of the GPAT1-variant transcript from the alternative promoter without SRE in the neonatal liver is roughly comparable to that in the adult liver. This is consistent with our observation that the alternative promoter is unmethylated in both the neonatal and adult livers, thereby suggesting the role for DNA methylation in the promoter-specific regulation of Gpam in the liver.

The change in hepatic gene expression before and after weaning could be regulated in response to nutritional demand. Indeed, we demonstrated that the lipogenic HF/HS diet fed to female mice during pregnancy and lactation results in decreased DNA methylation of the Gpam promoter in the liver of offspring, suggesting that the DNA methylation status can be modulated, at least in part, by the nutritional factors. Thus, the change in DNA methylation of the Gpam promoter is likely to be affected by the fetal and neonatal environments, such as nutrition, and/or be a programmed process of liver maturation.

Whether DNA methylation would affect hepatic de novo lipogenesis later in life is an important issue to be addressed. Previous reports showed that maternal overnutrition in animals contributes to the development of nonalcoholic fatty liver disease in adult offspring (27), suggesting that hepatic lipid metabolism is nutritionally affected early in life. In this study, maternal overnutrition caused decreased Gpam promoter methylation with increased GPAT1 expression and TG level in the liver of the offspring; however, the possibility cannot be excluded that increased lipid flux from dam, as well as increased de novo TG biosynthesis, might have affected the liver TG content of offspring. Further studies are required to understand whether DNA methylation can affect hepatic de novo lipogenesis and susceptibility to fatty liver-related diseases in later life.

In conclusion, this is the first demonstration of reciprocal change in DNA methylation of the Gpam promoter and its mRNA expression in the mouse liver before and after weaning (Fig. 5F). Our data suggest that in the neonatal liver, DNA methylation of the Gpam promoter containing SREs, which is likely to be induced by Dnmt3b, inhibits the recruitment of SREBP-1c, whereas in the adult liver, the decreased DNA methylation may result in active chromatin conformational change, thereby allowing the recruitment of SREBP-1c. This is the first detailed analysis of the DNA methylation-dependent regulation of TG biosynthesis gene in the liver, thereby leading to the better understanding of the molecular mechanism underlying the epigenetic regulation of metabolic genes and thus metabolic diseases.

ACKNOWLEDGMENTS

This work was supported in part by Grants-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology of Japan and the Ministry of Health, Labour and Welfare of Japan and research grants from "To promote basic research by research personnel in private-sector business (Japan Science and Technology Agency)," Mitsukoshi Health and Welfare Foundation, The Danone Institute of Japan Foundation, Nestle Nutrition Council, Novo Nordisk Study Award for Growth and Development, Ono Medical Research Foundation, and The Morinaga Foundation for Health and Nutrition.
