Abstract

We investigate spin-dependent parton distributions in the polarized virtual photon target in perturbative QCD up to the next-to-leading order (NLO). In the case $\Lambda^2 \ll P^2 \ll Q^2$, where $-Q^2 (-P^2)$ is the mass squared of the probe (target) photon, parton distributions can be predicted completely up to NLO, but they are factorization-scheme-dependent. We analyze parton distributions in six different factorization schemes and discuss their scheme dependence. We study, in particular, the QCD and QED axial anomaly effects on the first moments of parton distributions to see the interplay between the axial anomalies and factorization schemes. We also show that the factorization-scheme dependence is characterized by the large-$x$ behaviors of quark distributions in the virtual photon. Gluon distribution is predicted to be the same up to NLO among the six factorization schemes examined. In particular, the first moment of gluon distribution is found to be factorization-scheme independent up to NLO.
1 Introduction

In the two-photon process of $e^+e^-$ collision experiments, we can measure the structure functions of the virtual photon (Fig.1). The advantage in studying the virtual photon target is that, in the case

$$\Lambda^2 \ll P^2 \ll Q^2$$

(1.1)

where $-Q^2$ ($-P^2$) is the mass squared of the probe (target) photon, and $\Lambda$ is the QCD scale parameter, we can calculate the whole structure function up to the next-to-leading order (NLO) in QCD by the perturbative method, in contrast to the case of the real photon target where in NLO there exist non-perturbative pieces [1, 2]. The spin-independent structure functions $F_2^\gamma(x, Q^2, P^2)$ and $F_L^\gamma(x, Q^2, P^2)$ as well as the parton contents were studied in the leading order (LO) [3] and in NLO [4]-[9]. The target mass effect of unpolarized and polarized virtual photon structure in LO was discussed in Ref.[10].

The information on the spin structure of the photon would be provided by the resolved photon process in polarized version of the DESY electron and proton collider HERA [11, 12]. More directly, polarized photon structure function can be measured by the polarized $e^+e^-$ collision in the future linear colliders. For the real photon ($P^2 = 0$) target, there exists only one spin-dependent structure function, $g_1^\gamma(x, Q^2)$, which is equivalent to the structure function $W_4^\gamma(x, Q^2)$ ($g_1^\gamma \equiv 2W_4^\gamma$) discussed some time ago in [13, 14]. The LO QCD corrections to $g_1^\gamma$ for the real photon target was first calculated by one of the authors [15] and later in Refs.[16, 17], while the NLO QCD analysis was performed by Stratmann and Vogelsang [18]. The first moment of the photon structure function $g_1^\gamma$ has recently attracted attention in the literature [17, 19, 20, 21, 22] in connection with its relevance for the axial anomaly. More recently the present authors investigated [23] the spin-dependent structure function $g_1^\gamma(x, Q^2, P^2)$ of the virtual photon up to NLO in QCD, where $P^2$ is in the above kinematical region (1.1). The analysis was made in the framework of the operator product expansion (OPE) supplemented by the renormalization group method and also in the framework of the QCD improved parton model [24] using the DGLAP parton evolution equations.
In the past few years, accuracy of the experimental data on the spin-dependent structure function $g_1$ of the nucleon has been significantly improved [25]. Using these experimental data together with the already existing world data, several groups [26]-[29] have carried out the NLO QCD analyses on the polarized parton distributions in the nucleon. These parton distributions may be used for predicting the behaviors of other processes such as polarized Drell-Yan reactions and polarized semi-inclusive deep inelastic scatterings, and etc. However, parton distributions obtained from the NLO analyses are dependent on the factorization scheme employed. It is possible that parton distributions obtained in one scheme may be more appropriate to use than those in other schemes. In the case of nucleon target, however, it may be difficult to examine the features of each factorization scheme, since for the moment it is inevitable to resort to some assumptions in order to extract parton distributions from the experimental data.

On the other hand, it is remarkable that, in the case of virtual photon target with a virtual mass $-P^2$ being in the kinematical region of Eq.(1.1), not only the photon structure functions but also the parton distributions in the target can be predicted entirely up to NLO in QCD. Thus, comparing the parton distributions predicted by one scheme with those by other schemes, we can easily examine the features of each factorization scheme. In consequence, the virtual photon target may serve as an optimal place to study the behaviors of parton distributions and their factorization-scheme dependence.

In this paper we examine in detail the polarized parton (i.e., quark and gluon) distributions in the virtual photon target. The polarized parton distributions are particularly interesting due to the fact that they have relevance to the axial anomaly [30]. The interplay between the QCD axial anomaly and factorization schemes has already been discussed for the spin-dependent structure function $g_1$ of the nucleon [31]-[37]. It was explained there that the QCD axial anomaly effect is retained in the flavor-singlet quark distribution in the nucleon in the standard $\overline{\text{MS}}$ scheme, but it is shifted to the gluon coefficient function in such a scheme called chirally-invariant (CI) factorization scheme. Now it should be pointed out that the polarized photon target is unique in the sense that not only QCD but also the OED axial anomaly takes
place. The QED axial anomaly, which is U(1) anomaly, emerges when a quark has an electromagnetic charge. Thus the flavor-non-singlet quark distribution is also relevant, besides the flavor-singlet one. Depending upon factorization schemes, the QED axial anomaly effect resides in both the flavor-singlet and non-singlet polarized quark distributions in the virtual photon, or it is shifted to the photon coefficient function, in which case we arrive at an interesting result: the first moments of the polarized quark distributions in the virtual photon, both flavor singlet and non-singlet, vanish in NLO. Also we find that the large $x$-behaviors of polarized quark distributions dramatically vary from one factorization scheme to another. Indeed, for $x \to 1$, the quark distributions positively diverge or negatively diverge or remain finite, depending on factorization schemes.

We perform our analyses in six different factorization schemes, (i) $\overline{\text{MS}}$, (ii) CI (chirally invariant) (it is also called as JET) [37, 38], (iii) AB (Adler-Bardeen) [36], (iv) OS (off-shell) [36], (v) AR (Altarelli-Ross) [39], and finally (vi) DIS schemes [39], and see how the parton distributions change in each scheme. In particular, we study the axial anomaly effects on the first moments and the large-$x$ behaviors of parton distributions. Gluon distribution in the virtual photon is found to be the same up to NLO, at least among the factorization schemes considered in this paper. Furthermore, the first moment of gluon distribution turns out to be factorization-scheme independent up to NLO. Part of the result has been briefly reported elsewhere [40].

In the next section we discuss the polarized parton distributions in the virtual photon. The explicit expressions for the flavor singlet-(non-singlet-)quark and gluon distributions predicted in QCD up to NLO are given in Appendix A. In Sec. 3, we derive the transformation rules for the relevant two-loop anomalous dimensions and one-loop photon matrix elements from the $\overline{\text{MS}}$ scheme to other factorization schemes and then explain particular factorization schemes we consider in this paper. In Sec. 4, we examine the first moments of parton distributions with emphasis on the interplay between the QCD and QED axial anomalies and the factorization schemes. The behaviors of parton distributions near $x = 1$ and their factorization-scheme dependence are discussed in Sec. 5. The numerical analyses of parton distributions predicted by different factorization schemes will be given in Sec. 6. The final section
is devoted to the conclusion and discussion.

2 Polarized parton distributions in photon

Let $q_i^\pm(x, Q^2, P^2)$, $G_i^\pm(x, Q^2, P^2)$, $\Gamma_i^\pm(x, Q^2, P^2)$ be quark with $i$-flavor, gluon, and photon distribution functions with $\pm$ helicities of the longitudinally polarized virtual photon with mass $-P^2$. Then the spin-dependent parton distributions are defined as

$$
\Delta q_i \equiv q_i^+ + \bar{q}_i^- - q_i^- - \bar{q}_i^+,
\Delta G_i \equiv G_i^+ - G_i^-,
\Delta \Gamma_i \equiv \Gamma_i^+ - \Gamma_i^-.
$$

In the leading order of the electromagnetic coupling constant, $\alpha = e^2/4\pi$, $\Delta \Gamma_i$ does not evolve with $Q^2$ and is set to be $\Delta \Gamma_i(x, Q^2, P^2) = \delta(1 - x)$. For later convenience we use, instead of $\Delta q_i$, the flavor singlet and non-singlet combinations of spin-dependent quark distributions as follows:

$$
\Delta q_i^S \equiv \sum_i \Delta q_i^i,
\Delta q_i^{NS} \equiv \sum_i e_i^2 \left( \Delta q_i^i - \frac{\Delta q_i^S}{N_f} \right).
$$

In terms of these parton distributions, the polarized virtual photon structure function $g_1^\gamma(x, Q^2, P^2)$ is expressed in the QCD improved parton model as

$$
g_1^\gamma(x, Q^2, P^2) = \int_x^1 \frac{dy}{y} \left\{ \Delta q_i^S(y, Q^2, P^2) \Delta C_i^S(y, Q^2) + \Delta G_i(y, Q^2, P^2) \Delta C_i^G(y, Q^2) 
+ \Delta q_i^{NS}(y, Q^2, P^2) \Delta C_i^{NS}(y, Q^2) \right\} + \Delta C_i^\gamma(x, Q^2).
$$

where $\Delta C_i^S(\Delta C_i^{NS})$, $\Delta C_i^G$, and $\Delta C_i^\gamma$ are the coefficient functions corresponding to singlet(non-singlet)-quark, gluon, and photon, respectively, and are independent of $P^2$. The Mellin moments of $g_1^\gamma$ is written as

$$
g_1^\gamma(n, Q^2, P^2) = \Delta \tilde{C}^\gamma(n, Q^2) \cdot \Delta \tilde{q}^\gamma(n, Q^2, P^2),
$$

where

$$
\Delta \tilde{C}^\gamma(n, Q^2) = (\Delta C_i^S, \Delta C_i^G, \Delta C_i^{NS}, \Delta C_i^\gamma),
\Delta \tilde{q}^\gamma(n, Q^2, P^2) = (\Delta q_i^S, \Delta G_i, \Delta q_i^{NS}, \Delta \Gamma_i).
$$
and the matrix notation is implicit.

The explicit expressions of $\Delta q^\gamma_S$, $\Delta G^\gamma$, and $\Delta q^\gamma_{NS}$ up to NLO can be derived from Eq.(4.46) of Ref.[23], which are given in Appendix A. They are written in terms of one-(two-) loop hadronic anomalous dimensions $\Delta \gamma^{0,n}_{ij}$ ($\gamma^{(1),n}_{ij}$) ($i, j = \psi, G$) and $\Delta \gamma^{0,n}_{NS}$ ($\gamma^{(1),n}_{NS}$), one-(two-) loop anomalous dimensions $\Delta K^{0,n}_i$ ($\Delta K^{(1),n}_i$) ($i = \psi, G, NS$) which represent the mixing between photon and three hadronic operators $R^n_i$ ($i = \psi, G, NS$), and finally $\Delta A^n_i$, the one-loop photon matrix elements of hadronic operators renormalized at $\mu^2 = P^2 (= -p^2)$,

$$\langle \gamma(p) | R^n_i \mu \rangle \gamma(p) \rangle_{\mu^2 = P^2} = \frac{\alpha}{4\pi} \Delta A^n_i \quad (i = \psi, G, NS) .$$

The photon matrix elements $\Delta A^n_i$ are scheme-dependent. In one-loop order, they are given, in the $\overline{\text{MS}}$ scheme, by [34]

$$\Delta A^n_{\psi, \overline{\text{MS}}} = \frac{\langle e^2 \rangle}{\langle e^4 \rangle - \langle e^2 \rangle^2} \Delta A^n_{\psi, \overline{\text{MS}}} \quad (3.1)$$

$$\Delta A^n_{G, \overline{\text{MS}}} = 0 ,$$

where $S_1(n) = \sum_{j=1}^{n} \frac{1}{j}$.

### 3 Factorization schemes

#### 3.1 Transformation rules from $\overline{\text{MS}}$ scheme to $a$-scheme

Although $g_1^\gamma$ is a physical quantity and thus unique, there remains a freedom in the factorization of $g_1^\gamma$ into $\Delta \tilde{C}^\gamma$ and $\Delta \tilde{q}^\gamma$. Given the formula Eq.(2.3), we can always redefine $\Delta \tilde{C}^\gamma$ and $\Delta \tilde{q}^\gamma$ as follows [42]:

$$\Delta \tilde{C}^\gamma(n, Q^2) \rightarrow \Delta \tilde{C}^\gamma(n, Q^2)|_a \equiv \Delta \tilde{C}^\gamma(n, Q^2)Z_a^{-1}(n, Q^2) , \quad (3.1)$$

$$\Delta \tilde{q}^\gamma(n, Q^2, P^2) \rightarrow \Delta \tilde{q}^\gamma(n, Q^2, P^2)|_a \equiv Z_a(n, Q^2) \Delta \tilde{q}^\gamma(n, Q^2, P^2) , \quad (3.2)$$

where $\Delta \tilde{C}^\gamma|_a$ and $\Delta \tilde{q}^\gamma|_a$ correspond to the quantities in a new factorization scheme-$a$. Note that the coefficient functions and anomalous dimensions are closely connected
under factorization. We will study the factorization scheme dependence of parton
distribution up to NLO, by which we mean that a scheme transformation for the
coefficient functions is considered up to the one-loop order, since a NLO prediction
for $g^2_1$ is given by the one-loop coefficient functions and anomalous dimensions up
to the two-loop order.

The most general form of a transformation for the coefficient functions in one-
loop order, from the $\overline{\text{MS}}$ scheme to a new factorization scheme-$a$, is given by

$$
\Delta C_{\gamma, n, a} = \Delta C_{\gamma, n, \overline{\text{MS}}} - \langle e^2 \rangle \frac{\alpha_s}{2\pi} \Delta w_S(n, a) ,
$$

$$
\Delta C_{G, n, a} = \Delta C_{G, n, \overline{\text{MS}}} - \langle e^2 \rangle \frac{\alpha_s}{2\pi} \Delta z(n, a) ,
$$

$$
\Delta C_{NS, n, a} = \Delta C_{NS, n, \overline{\text{MS}}} - \frac{\alpha_s}{2\pi} \Delta w_{NS}(n, a) ,
$$

$$
\Delta C_{\gamma, n, a} = \Delta C_{\gamma, n, \overline{\text{MS}}} - \frac{\alpha_s}{\pi} 3\langle e^4 \rangle \Delta \hat{z}(n, a) ,
$$

where $\langle e^4 \rangle = \sum_i e_i^4/N_f$. The flavor-singlet(nonsinglet) quark coefficient functions
are expanded up to the one-loop order as

$$
\Delta C_{S, n} = \langle e^2 \rangle \left(1 + \frac{\alpha_s}{4\pi} \Delta B^n_S + \mathcal{O}(\alpha_s^2) \right) ,
$$

$$
\Delta C_{NS, n} = 1 + \frac{\alpha_s}{4\pi} \Delta B^n_{NS} + \mathcal{O}(\alpha_s^2) ,
$$

with $\Delta B^n_S = \Delta B^n_{NS}$. The $\Delta z(n, a)$ ($\Delta \hat{z}(n, a)$) term tells how much of the QCD
(QED) axial anomaly effect is transferred to the coefficient function in the new
factorization scheme. The gluon and photon coefficient functions $\Delta C_{G, n}^\gamma$ and $\Delta C_{\gamma, n}^\gamma$
start from the one-loop order (i.e., from the NLO):

$$
\Delta C_{G, n}^\gamma = \langle e^2 \rangle \left(\frac{\alpha_s}{4\pi} \Delta B^n_G + \mathcal{O}(\alpha_s^2) \right) ,
$$

$$
\Delta C_{\gamma, n}^\gamma = \frac{\alpha}{4\pi} 3N_f \langle e^4 \rangle \left(\Delta B^n_G + \mathcal{O}(\alpha_s) \right) .
$$

In the $\overline{\text{MS}}$ scheme, $\Delta C_{\gamma, n}^\gamma_{\overline{\text{MS}}}$ has been obtained from $\Delta C_{G, n}^\gamma_{\overline{\text{MS}}}$, with changes: $\alpha_s/2\pi \rightarrow (2\alpha/\alpha_s) \times (\alpha_s/2\pi)$, $\langle e^2 \rangle \rightarrow 3\langle e^4 \rangle$, and 3 is the number of colors. Thus we have

$$
\Delta B^n_{\gamma, \overline{\text{MS}}} = \frac{2}{N_f} \Delta B^n_G_{\overline{\text{MS}}} .
$$
Since, in the leading order, coefficient functions are given by
\[
\Delta C_{\text{MS}}^{\gamma}|_{\text{LO}} = \Delta C_{a}^{\gamma}|_{\text{LO}} = ((e^2), 0, 1, 0)
\] (3.7)
the relations (3.3) between the coefficient functions in the \(a\)-scheme and \(\overline{\text{MS}}\) scheme lead to \(Z_{a}^{-1}(n, Q^2)\), which is expressed as
\[
Z_{a}^{-1}(n, Q^2) = I - \begin{pmatrix}
\frac{\alpha_s}{2\pi} \Delta w_S(n, a) & \frac{\alpha_s}{2\pi} \Delta z(n, a) & 0 & \frac{\alpha_s}{\pi} 3(e^2) \Delta \hat{z}(n, a) \\
0 & 0 & \frac{\alpha_s}{2\pi} \Delta w_N S(n, a) & \frac{\alpha_s}{\pi} 3(e^4 - (e^2)^2) \Delta \hat{z}(n, a) \\
0 & 0 & \frac{\alpha_s}{2\pi} \Delta w_N G(n, a) & \frac{\alpha_s}{\pi} 3(e^2) \Delta \hat{z}(n, a) \\
0 & 0 & 0 & 0
\end{pmatrix} ,
\] (3.8)
where \(I\) is a 4 \(\times\) 4 unit matrix.

Now we derive corresponding transformation rules from \(\overline{\text{MS}}\) scheme to \(a\)-scheme for the relevant two-loop anomalous dimensions. The parton distribution functions \(\Delta \tilde{q}^\gamma(n, Q^2, P^2)\) satisfy the following evolution equation [39, 42, 43, 44, 45]:
\[
\frac{d\Delta \tilde{q}^\gamma(n, Q^2, P^2)}{d \ln Q^2} = \Delta \tilde{P}(n, Q^2) \Delta \tilde{q}^\gamma(n, Q^2, P^2) ,
\] (3.9)
where
\[
\Delta \tilde{P}(n, Q^2) = \begin{pmatrix}
\Delta P_{\psi \psi}(n, Q^2) & \Delta P_{\psi G}(n, Q^2) & 0 & \Delta k_S(n, Q^2) \\
\Delta P_{G \psi}(n, Q^2) & \Delta P_{G G}(n, Q^2) & 0 & \Delta k_G(n, Q^2) \\
0 & 0 & \Delta P_{N S}(n, Q^2) & \Delta k_{N S}(n, Q^2) \\
0 & 0 & 0 & 0
\end{pmatrix} .
\] (3.10)
From Eq.(3.2), we obtain
\[
\frac{d\Delta \tilde{q}^\gamma(n, Q^2, P^2)}{d \ln Q^2} = \frac{dZ_a(n, Q^2)}{d \ln Q^2} \Delta \tilde{q}^\gamma(n, Q^2, P^2)|_\text{MS} + Z_a(n, Q^2) \frac{d\Delta \tilde{q}^\gamma(n, Q^2, P^2)}{d \ln Q^2} |_\text{MS}
\]
\[
= \Delta \tilde{P}(n, Q^2)|_a \Delta \tilde{q}^\gamma(n, Q^2, P^2)|_a ,
\] (3.11)
with
\[
\Delta \tilde{P}(n, Q^2)|_a = \left[ \frac{dZ_a(n, Q^2)}{d \ln Q^2} + Z_a(n, Q^2) \Delta \tilde{P}(n, Q^2)|_\text{MS} \right] Z_a^{-1}(n, Q^2) .
\] (3.12)
The splitting functions $\Delta P_i(n, Q^2)$ ($i = \psi\psi, \psi G, G\psi, GG,$ and $NS$) and $\Delta k_j(n, Q^2)$ ($j = S, G, NS$) are expanded as

$$\Delta P_i(n, Q^2) = \frac{\alpha_s(Q^2)}{2\pi} \Delta P^{(0)}_i(n) + \left[ \frac{\alpha_s(Q^2)}{2\pi} \right]^2 \Delta P^{(1)}_i(n) + \cdots,$$

(3.13)

$$\Delta k_j(n, Q^2) = \frac{\alpha}{2\pi} \Delta k^{(0)}_j(n) + \frac{\alpha \alpha_s(Q^2)}{(2\pi)^2} \Delta k^{(1)}_j(n) + \cdots,$$

(3.14)

Since the QCD effective coupling constant $\alpha_s(Q^2)$ satisfies

$$\frac{d \alpha_s(Q^2)}{d \ln Q^2} = -\beta_0 \frac{\alpha_s(Q^2)^2}{4\pi} + \cdots,$$

(3.15)

where $\beta_0 = 11 - \frac{2}{3} N_f$ is the one-loop coefficient of the QCD beta function, and the $n$-th anomalous dimensions are defined as

$$\Delta P^{(0)}_i(n) = \frac{1}{4} \Delta \gamma^0_{i,n}, \quad \Delta P^{(1)}_i(n) = -\frac{1}{8} \Delta \gamma^{(1),n}_{i,n},$$

(3.16)

$$\Delta k^{(0)}_j(n) = \frac{1}{4} \Delta K^0_{j,n}, \quad \Delta k^{(1)}_j(n) = \frac{1}{8} \Delta K^{(1),n}_{j,n},$$

(3.17)

we find for one-loop

$$\Delta \gamma^0_{i,n} = \Delta \gamma^0_{i,n, MS}, \quad \Delta K^0_{j,n} = \Delta K^0_{j,n, MS},$$

(3.18)

and for two-loop

$$\Delta \gamma^{(1),n}_{\psi\psi, a} = \Delta \gamma^{(1),n}_{\psi\psi, MS} + 2 \Delta z(n, a) \Delta \gamma^0_{\psi\psi} + 2 \beta_0 \Delta w_S(n, a) \Delta \gamma^0_{\psi\psi},$$

$$\Delta \gamma^{(1),n}_{\psi G, a} = \Delta \gamma^{(1),n}_{\psi G, MS} + 2 \Delta z(n, a) \left[ \Delta \gamma^0_{\psi G} - \Delta \gamma^0_{\psi\psi} + 2 \beta_0 \right] + 2 \Delta w_S(n, a) \Delta \gamma^0_{\psi\psi},$$

$$\Delta \gamma^{(1),n}_{G\psi, a} = \Delta \gamma^{(1),n}_{G\psi, MS} - 2 \Delta w_S(n, a) \Delta \gamma^0_{\psi G},$$

$$\Delta \gamma^{(1),n}_{GG, a} = \Delta \gamma^{(1),n}_{GG, MS} - 2 \Delta z(n, a) \Delta \gamma^0_{G\psi},$$

$$\Delta \gamma^{(1),n}_{NS, a} = \Delta \gamma^{(1),n}_{NS, MS} + 4 \beta_0 \Delta w_{NS}(n, a),$$

(3.19)

$$\Delta K^{(1),n}_{S, a} = \Delta K^{(1),n}_{S, MS} + 2 \Delta w_S(n, a) \Delta K^0_{S} + 4 \Delta \tilde{z}(n, a) 3(e^2) \Delta \gamma^0_{\psi\psi},$$

$$\Delta K^{(1),n}_{G, a} = \Delta K^{(1),n}_{G, MS} + 4 \Delta \tilde{z}(n, a) 3(e^2) \Delta \gamma^0_{G\psi},$$

$$\Delta K^{(1),n}_{NS, a} = \Delta K^{(1),n}_{NS, MS} + 2 \Delta w_{NS}(n, a) \Delta K^0_{NS} + 4 \Delta \tilde{z}(n, a) 3(\langle e^4 \rangle - \langle e^2 \rangle^2) \Delta \gamma^0_{NS}.$$
The one-loop photon matrix elements of the hadronic operators, $\Delta A^n_\psi$ and $\Delta A^n_{NS}$ in Eq.(2.4), are related to each other as

$$\Delta A^n_{NS} = \Delta A^n_\psi \frac{\langle e^4 \rangle - \langle e^2 \rangle^2}{\langle e^2 \rangle},$$

(3.20)

and the sum

$$\left( \Delta C_{\gamma^n} \frac{\alpha}{4\pi} + \langle e^2 \rangle \Delta A^n_\psi + \Delta A^n_{NS} \right)$$

(3.21)

is factorization-scheme-independent in one-loop order [23]. Thus we obtain from Eq.(3.3)

$$\Delta A^n_{\psi,a} = \Delta A^n_{\psi,\overline{\text{MS}}} + 12 \langle e^2 \rangle \hat{\Delta}z(n,a),$$

$$\Delta A^n_{G,a} = \Delta A^n_{G,\overline{\text{MS}}} = 0,$$

$$\Delta A^n_{NS,a} = \Delta A^n_{NS,\overline{\text{MS}}} + 12(\langle e^4 \rangle - \langle e^2 \rangle^2) \hat{\Delta}z(n,a).$$

(3.22)

Note that $\Delta A^n_G = 0$ in one-loop order.

It is possible to choose $\Delta z(n,a)$ and $\hat{\Delta}z(n,a)$ arbitrarily. In the following, we take $\hat{\Delta}z(n,a) = \Delta z(n,a)$ in the CI-like schemes and $\hat{\Delta}z(n,\text{DIS}_\gamma) \neq \Delta z(n,\text{DIS}_\gamma) = 0$ in the DIS scheme. In one-loop order we have $\Delta w_S(n,a) = \Delta w_{NS}(n,a)$. Thus from now on, we set $\Delta w_S(n,a) = \Delta w_{NS}(n,a) \equiv \Delta w(n,a)$. Let us now discuss the features of several factorization schemes.

### 3.2 The $\overline{\text{MS}}$ scheme

This is the only scheme in which both relevant one-loop coefficient functions and two-loop anomalous dimensions were actually calculated [34, 46, 47, 48]. In fact there still remain ambiguities in the $\overline{\text{MS}}$ scheme, depending on how to handle $\gamma_5$ in $n$ dimensions. The $\overline{\text{MS}}$ scheme we call here is the one due to Mertig and van Neerven [47] and Vogelsang [48], in which the first moment of the non-singlet quark operator vanishes, corresponding to the conservation of the non-singlet axial current. Indeed we have $\Delta \gamma^{(1)}_{\overline{\text{MS}},n=1} = 0$. Explicit expressions of the relevant one-loop coefficient functions and two-loop anomalous dimensions can be found, for example, in Appendix of Ref. [23]. It is noted that, in the $\overline{\text{MS}}$ scheme, both the QCD and
QED axial anomalies reside in the quark distributions and not in the gluon and photon coefficient functions. In fact we observe
\begin{align*}
\Delta \gamma_{\psi, \text{MS}}^{(1), n=1} &= 0, \\
\Delta B_{G, \text{MS}}^{n=1} &= 0.
\end{align*}
(3.23)
(3.24)
where $C_F = \frac{4}{3}$ and $T_f = \frac{N_f}{2}$. Also we find from Eq.(2.3) that the first moments of the one-loop photon matrix elements of quark operators gain the non-zero values, i.e.,
\begin{equation}
\Delta A_{\psi, \text{MS}}^{n=1} = \frac{\langle e^2 \rangle}{\langle e^4 \rangle - \langle e^2 \rangle^2} \Delta A_{\psi, \text{NS, MS}}^{n=1} = -12\langle e^2 \rangle N_f,
\end{equation}
(3.25)
which is due to the QED axial anomaly.

### 3.3 The CI-like schemes

The EMC measurement \cite{49} of the first moment of the proton spin structure function $g_1^p(x, Q^2)$ presented us with an issue called “proton spin crisis”. Since then many ideas have been proposed as solutions. One simple and plausible explanation was that there exists an anomalous gluon contribution to the first moment \cite{31}-\cite{33} originating from the QCD axial anomaly. This explanation was later \cite{34} supported with a notion of the factorization-scheme dependence. There is a set of the factorization schemes in which we obtain
\begin{equation}
\Delta B_{G, \text{CI-like}}^{n=1} = -2N_f, \quad \Delta \gamma_{\psi, \text{CI-like}}^{(1), n=1} = 0.
\end{equation}
(3.26)
Let us call them CI-like schemes. In this paper we consider four CI-like schemes, in which we take $\Delta z(n, a) = \Delta \hat{z}(n, a)$, since both QCD and QED anomalies originate from the similar triangle diagrams. With this choice, the relation between the one-loop gluon and photon coefficient functions, which holds in the $\overline{\text{MS}}$ scheme, also holds in the CI-like schemes,
\begin{equation}
\Delta B_{\gamma, \text{CI-like}}^{n} = \frac{2}{N_f} \Delta B_{G, \text{CI-like}}^{n}.
\end{equation}
(3.27)
Thus, in addition to the relations in Eq.(3.26), we obtain in the CI-like schemes
\begin{align*}
\Delta B_{\gamma, \text{CI-like}}^{n=1} &= -4, \\
\Delta A_{\psi, \text{CI-like}}^{n=1} &= \Delta A_{\psi, \text{NS, CI-like}}^{n=1} = 0.
\end{align*}
(3.28)
(i) [The chirally invariant (CI) scheme] In this scheme the factorization of the photon-gluon (phototon-phototon) cross section into the hard and soft parts is made so that chiral symmetry is respected \cite{37, 38} and the QCD and QED anomaly effects are absorbed into the gluon and photon coefficient functions. Thus the spin-dependent quark distributions in the CI scheme are anomaly-free. The transformation from the \( \overline{\text{MS}} \) scheme to the CI scheme is achieved by

\[
\Delta w(n, a = \text{CI}) = 0, \quad \Delta z(n, a = \text{CI}) = \Delta \hat{z}(n, a = \text{CI}) = 2N_f \frac{1}{n(n + 1)}. \tag{3.29}
\]

It has been argued by Cheng \cite{37} and Müller and Teryaev \cite{38} that the \( x \)-dependence of the axial-anomaly effect is uniquely fixed and that its \( x \)-behavior leads to the transformation rule (3.29) and thus to the CI scheme.

(ii) [The Adler-Bardeen (AB) scheme] Ball, Forte and Ridolfi \cite{36} proposed several CI-like schemes for the analysis of the nucleon spin structure function \( g_1(x, Q^2) \). One of them is the Adler-Bardeen (AB) scheme which was introduced by requiring that the change from the \( \overline{\text{MS}} \) scheme to this scheme be independent of \( x \), so that the large and small \( x \) behavior of the gluon coefficient function is unchanged. In our case, we have in momentum space

\[
\Delta w(n, a = \text{AB}) = 0, \quad \Delta z(n, a = \text{AB}) = \Delta \hat{z}(n, a = \text{AB}) = N_f \frac{1}{n}. \tag{3.30}
\]

(iii) [The off-shell (OS) scheme] In this scheme \cite{36} we renormalize operators while keeping the incoming particle off-shell, \( p^2 \neq 0 \), so that at renormalization (factorization) point \( \mu^2 = -p^2 \), the finite terms vanish. This is exactly the same as “the momentum subtraction scheme” which was used some time ago to calculate, for instance, the polarized quark and gluon coefficient functions \cite{50, 30}. The CI-relations in Eqs. (3.26) and (3.28) also hold in the OS scheme \cite{51}, since the axial anomaly appears as a finite term in the calculation of the triangle graph for \( j_5^5 \) between external gluons (photons) and the finite term is thrown away in this scheme. The transformation from the \( \overline{\text{MS}} \) scheme to the OS scheme is made by choosing

\[
\Delta w(n, a = \text{OS}) = C_F \left[ \left[ S_1(n) \right]^2 + 3S_2(n) - S_1(n) \left( \frac{1}{n} - \frac{1}{n+1} \right) \right].
\]
\[
\Delta z(n, a = \text{OS}) = \Delta \hat{z}(n, a = \text{OS}) = \frac{n - 1}{n(n + 1)} S_1(n) + \frac{1}{n} + \frac{1 + 2}{n(n + 1)^2} \].
\]

\[
\Delta A_{\psi, \text{OS}}^n = \Delta A_{NS, \text{OS}}^n = 0 \text{ not only for } n = 1 \text{ but also for all } n.
\]

(iv) [The Altarelli-Ross (AR) scheme] Using massive quark as a regulator for collinear divergence, Altarelli and Ross \cite{31, 52} derived the same one-loop gluon coefficient function \( \Delta C_G^\gamma \) as in the case of CI scheme. In order to obtain the one-loop quark coefficient function in this scheme, however, we need to do an extra subtraction so that the conservation of the nonsinglet axial currents is secured \cite{53}.

The transformation rule is

\[
\Delta w_S(n, a = \text{AR}) = C_F \left\{ 2 \left[ S_1(n) \right]^2 + 2 S_2(n) - S_1(n) \left( \frac{2}{n} - \frac{2}{n + 1} + 2 \right) - 2 + \frac{1}{n} - \frac{1 + 2}{n(n + 1)^2} \right\},
\]

\[
\Delta z(n, a = \text{AR}) = \Delta \hat{z}(n, a = \text{AR}) = 2 N_f \frac{1}{n(n + 1)}. \]

### 3.4 The DIS_\gamma scheme

An interesting factorization scheme, which is called DIS_\gamma, was introduced some time ago into the NLO analysis of the unpolarized real photon structure function \( F_2^\gamma(x, Q^2) \). Glück, Reya and Vogt \cite{39} observed that, in the \( \overline{\text{MS}} \) scheme, the \( \ln(1-x) \) term in the photonic coefficient function \( C_2^\gamma(x) \) for \( F_2^\gamma \), which becomes negative and divergent for \( x \to 1 \), drives the ‘pointlike’ part of \( F_2^\gamma \) to large negative values as \( x \to 1 \), leading to a strong difference between the LO and the NLO results for \( F_2^\gamma, \text{pointlike} \) in the large-\( x \) region. They introduced the DIS_\gamma scheme in which the photonic coefficient function \( C_2^\gamma \), i.e., the direct-photon contribution to \( F_2^\gamma \), is absorbed into the photonic quark distributions. It is noted that, for the real photon target, the structure function \( F_2^\gamma \) is decomposed into a ‘pointlike’ and a ‘hadronic’ part, the former being perturbatively calculable but not the latter. And beyond the
LO both the ‘pointlike’ and the ‘hadronic’ parts depend on the factorization scheme employed. A similar situation occurs in the polarized case, and the DIS$_\gamma$ scheme was applied to the NLO analysis for the spin-dependent structure function $g_1^\gamma(x, Q^2)$ of the real photon target by Stratmann and Vogelsang [18].

In the polarized version of DIS$_\gamma$ scheme we take

$$
\Delta w_S(n, \text{DIS}_\gamma) = \Delta w_{NS}(n, \text{DIS}_\gamma) = \Delta z(n, \text{DIS}_\gamma) = 0 , \quad (3.34)
$$

$$
\Delta \hat{z}(n, \text{DIS}_\gamma) = \frac{N_f}{4} \Delta B_n^\gamma, \text{MS} \\
= N_f \left\{ \frac{n - 1}{n(n + 1)} S_1(n) + \frac{3}{n} - \frac{4}{n + 1} - \frac{1}{n^2} \right\} , \quad (3.35)
$$

so that

$$
\Delta B_n^\gamma, \text{DIS}_\gamma = \Delta B_n^\gamma, \text{MS} - \frac{4}{N_f} \Delta \hat{z}(n, \text{DIS}_\gamma) \\
= 0 . \quad (3.36)
$$

Note that the relation à la Eqs.(3.6) and (3.27) in the $\overline{\text{MS}}$ and CI-like factorization schemes does not hold anymore in this scheme, i.e.,

$$
\Delta B_n^\gamma, \text{DIS}_\gamma \neq \frac{2}{N_f} \Delta B_n^\gamma, \text{DIS}_\gamma \left( = \frac{2}{N_f} \Delta B_n^\gamma, \overline{\text{MS}} \right) . \quad (3.37)
$$

For $n = 1$, we have

$$
\Delta \hat{z}(n = 1, \text{DIS}_\gamma) = 0 , \quad (3.38)
$$

and thus, together with Eq.(3.34), we observe that as far as the first moments are concerned, DIS$_\gamma$ scheme gives the same results with $\overline{\text{MS}}$. In other words, in the DIS$_\gamma$ scheme, both the QCD and QED axial anomaly effects are retained in the quark distributions.

With these preparations, we now examine the factorization scheme dependence of the polarized parton distributions in the virtual photon. The two-loop anomalous dimensions of the spin-dependent operators and one-loop photon matrix elements of the hadronic operators in the $\overline{\text{MS}}$ scheme are already known. Corresponding quantities in a particular scheme are obtained through the transformation rules given in Eq.(3.19). Inserting these quantities into the formulas given in Appendix A, we get the NLO predictions for the moments of polarized parton distributions in a particular factorization scheme.
3.5 Gluon distribution in the virtual photon

Let us start with the gluon distribution. We find that all the factorization schemes which we consider in this paper predict the same behavior for the gluon distribution up to NLO:

$$\Delta G^\gamma(n, Q^2, P^2)|_a = \Delta G^\gamma(n, Q^2, P^2)|_{\text{MS}},$$

(3.39)

where $a$ means factorization schemes of CI, AB, OS, AR and DIS. This can be seen from the direct calculation or from the notion that, up to NLO, $\Delta G^\gamma|_a$ satisfies the same evolution equation as $\Delta G^\gamma|_{\text{MS}}$ with the same initial condition at $Q^2 = P^2$, namely, $\Delta G^\gamma(n, P^2, P^2)|_a = \Delta G^\gamma(n, P^2, P^2)|_{\text{MS}} = 0$.

If we consider a more general factorization scheme in which the hadronic part of $Z^{-1}_a(n, Q^2)$ in Eq.(3.8) is replaced with a new one as follows,

$$(1 - \frac{\alpha_s}{2\pi}\Delta w_S - \frac{\alpha_s}{2\pi}\Delta z) \rightarrow (1 - \frac{\alpha_s}{2\pi}\Delta w_S - \frac{\alpha_s}{2\pi}\Delta z - \frac{\alpha_s}{2\pi}\Delta u),$$

(3.40)

then, in this new factorization scheme, the predicted gluon distribution is not the same with $\Delta G^\gamma(n, Q^2, P^2)|_{\text{MS}}$ in NLO. However, the first moment is found to be still the same. In other words, the first moment of the gluon distribution in the virtual photon, $\Delta G^\gamma(n = 1, Q^2, P^2)$, is factorization-scheme independent up to NLO. This is due to the fact that the new terms, which appear by the inclusion of $\Delta u$ and $\Delta v$, will be proportional to $\Delta K_{\psi}^{0,n}$ and that $\Delta K_{\psi}^{0,n=1} = 0$. Also inclusion of $\Delta u$ and $\Delta v$ terms in $Z_a^{-1}$ does not modify the photon structure function $g_1^\gamma(x, Q^2, P^2)$ itself up to NLO, since the gluon coefficient function starts in the order $\alpha_s$. Moreover, the quark distributions in the virtual photon do not change by the inclusion of $\Delta u$ and $\Delta v$ terms.

4 The $n = 1$ moments of parton distributions

The first moments of polarized parton distributions in the virtual photon are particularly interesting since they have relevance to the QCD and QED axial anomalies. The explicit expressions for the moments of $\Delta q_3^\gamma$, $\Delta G^\gamma$, and $\Delta q_{NS}^\gamma$ up to NLO are given in Appendix A. We take the $n \rightarrow 1$ limit in these expressions. Useful $n = 1$ moments of one- and two-loop anomalous dimensions, photon matrix elements, and
coefficient functions both in the $\overline{\text{MS}}$ and CI-like schemes are enumerated in Appendix B. As far as the first moments are concerned, DIS scheme gives the same results with $\overline{\text{MS}}$. Note that we have

$$\lambda_{+}^{n=1} = 0, \quad \lambda_{-}^{n=1} = -2\beta_{0}, \quad \lambda_{NS}^{n=1} (= \Delta \gamma_{NS}^{0,n=1}) = 0,$$

where $\lambda_{\pm}^{n=1}$ are eigenvalues of the one-loop hadronic anomalous dimension matrix $\Delta \gamma_{ij}^{0,n=1}$. The zero eigenvalues $\lambda_{+}^{n=1} = \lambda_{NS}^{n=1} = 0$ correspond to the conservation of the axial-vector current at one-loop order.

### 4.1 The $n = 1$ moment of gluon distribution

The expressions for the moments of gluon distribution are given in Appendix A.2. In these expressions the factors

$$\frac{1}{\lambda_{+}^{n}}, \quad \frac{1}{2\beta_{0} + \lambda_{-}^{n}}, \quad \frac{1}{2\beta_{0} + \lambda_{-}^{n} - \lambda_{+}^{n}},$$

may develop singularities at $n = 1$ and so we need a little care when we deal with them. Taking the limit of $n$ going to 1, we find

$$\hat{L}_{G}^{+n} \to 0, \quad \hat{L}_{G}^{-n} \to \text{finite}, \quad \hat{A}_{G}^{+n} \to \text{finite}, \quad \hat{B}_{G}^{+n} \to 0, \quad \hat{B}_{G}^{-n} \to \text{finite}, \quad \hat{A}_{G}^{-n} \to 72\langle e^{2}\rangle N_{f}C_{F}.$$ (4.3)

The terms proportional to $\hat{L}_{G}^{-n}, \hat{B}_{G}^{-n},$ and $\hat{A}_{G}^{+n}$ all vanish in the $n = 1$ limit, since they are multiplied by the following vanishing factors:

$$\left\{ 1 - \frac{\alpha_{s}(Q^{2})}{\alpha_{s}(P^{2})} \frac{\lambda_{-}^{n}/2\beta_{0} + 1}{\lambda_{+}^{n}/2\beta_{0}} \right\}, \quad \left\{ 1 - \frac{\alpha_{s}(Q^{2})}{\alpha_{s}(P^{2})} \frac{\lambda_{+}^{n}/2\beta_{0}}{\lambda_{-}^{n}/2\beta_{0}} \right\}. \quad (4.4)$$

Only exception is the term proportional to $\hat{A}_{G}^{-n}$. We find for $n \to 1$

$$\hat{A}_{G}^{-n} \left\{ 1 - \frac{\alpha_{s}(Q^{2})}{\alpha_{s}(P^{2})} \frac{\lambda_{-}^{n}/2\beta_{0}}{\lambda_{+}^{n}/2\beta_{0}} \right\} \to 72\langle e^{2}\rangle N_{f}C_{F} \frac{\alpha_{s}(Q^{2}) - \alpha_{s}(P^{2})}{\alpha_{s}(Q^{2})}. \quad (4.5)$$

Thus we obtain

$$\Delta G^{n}(n = 1, Q^{2}, P^{2}) = \frac{12\alpha}{\pi\beta_{0}} \langle e^{2}\rangle N_{f} \frac{\alpha_{s}(Q^{2}) - \alpha_{s}(P^{2})}{\alpha_{s}(Q^{2})}. \quad (4.6)$$

for the first moment of the gluon distribution in the virtual photon. It should be emphasized that the result is factorization-scheme independent.
4.2 The $n = 1$ moment of quark distributions

The expressions for the moments of quark distributions are given in Appendix A.1 and A.3. In all the factorization schemes under study, i.e., $\overline{\text{MS}}$, DIS, and CI-like schemes, we find for $n \to 1$,

\[
\hat{L}_S^n \to 0, \quad \hat{L}_S^{-n} \to 0, \quad \hat{L}_{NS}^n \to 0, \\
\hat{A}_S^n \to \text{finite}, \quad \hat{A}_S^{-n} \to 0, \quad \hat{A}_{NS}^n \to \text{finite} \\
\hat{B}_S^n \to 0, \quad \hat{B}_S^{-n} \to \text{finite}, \quad \hat{B}_{NS}^n \to 0.
\]

(4.7)

The terms proportional to $\hat{A}_S^n$ and $\hat{B}_S^{-n}$ are multiplied by the vanishing factors in Eq. (4.4), and the $\hat{A}_{NS}^n$ term multiplied by \[
\left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_{NS}/2\beta_0} \right\},
\]

(4.8)

and, therefore, the $\hat{L}_S^n$, $\hat{L}_S^{-n}$, $\hat{L}_{NS}^n$, $\hat{A}_S^n$, $\hat{A}_S^{-n}$, $\hat{A}_{NS}^n$, $\hat{B}_S^n$, $\hat{B}_S^{-n}$, and $\hat{B}_{NS}^n$ terms in Eqs. (A.1) and (A.17) all vanish in the $n = 1$ limit. Then the first moments of quark distributions are given by

\[
\Delta q_S^\gamma(n = 1, Q^2, P^2) = \frac{\alpha}{8\pi\beta_0} \hat{C}_{S}^{n=1} = \frac{\alpha}{4\pi} \Delta A_{\psi}^{n=1}, \\
\Delta q_{NS}^\gamma(n = 1, Q^2, P^2) = \frac{\alpha}{8\pi\beta_0} \hat{C}_{NS}^{n=1} = \frac{\alpha}{4\pi} \Delta A_{NS}^{n=1}.
\]

(4.9) (4.10)

We now see that scheme dependence for the first moments of quark distributions is coming from the photon matrix elements $\Delta A_{\psi}^n$ and $\Delta A_{NS}^n$.

In the case of CI-like factorization schemes, $a = \text{CI, AB, OS, AR}$, we have

\[
\Delta w(n = 1, a) = 0, \\
\Delta z(n = 1, a) = \Delta \hat{z}(n = 1, a) = N_f \quad \text{for } a = \text{CI, AB, OS, AR}.
\]

(4.11)

We find from Eqs. (3.22) and (3.23) that these schemes give \[
\Delta A_{\psi, a}^{n=1} = \Delta A_{NS, a}^{n=1} = 0.
\]

(4.12)
This leads to an interesting result: The first moment of spin-dependent quark distributions in the virtual photon vanish in NLO for \( a = \text{CI}, \text{AB}, \text{OS}, \text{AR} \).

\[
\Delta q^\gamma_S(n = 1, Q^2, P^2)|_a = \Delta q^\gamma_N S(n = 1, Q^2, P^2)|_a = 0 \quad (4.13)
\]

The vanishing first moments imply that the axial anomaly effects do not reside in the quark distributions. In these CI-like schemes, the QCD and QED axial anomalies are transferred to the gluon and photon coefficient functions, respectively, and their first moments do not vanish. Indeed we obtain from Eqs.\((3.1)\) and\((3.8)\)

\[
\Delta C^\gamma_{G, n=1, a} = -\langle e^2 \rangle \frac{\alpha_s(Q^2)}{2\pi} N_f \quad (4.14)
\]

\[
\Delta C^\gamma_{\gamma, n=1, a} = -\frac{3\alpha}{\pi} \langle e^4 \rangle N_f \left( 1 - \frac{\alpha_s(Q^2)}{\pi} \right) \quad \text{for } a = \text{CI}, \text{AB}, \text{OS}, \text{AR} \quad (4.15)
\]

where we have used the fact \([46, 54, 23]\)

\[
\Delta q^\gamma_S(n = 1) \bigg|_{\text{MS}} = \Delta q^\gamma_N S(n = 1) \bigg|_{\text{MS}} = \left[ -\frac{\alpha}{\pi} \right] N_f \left( 1 - \frac{2\alpha_s(P^2)}{\beta_0} \right) \quad (4.16)
\]

\[
\Delta q^\gamma_{NS, n=1} \bigg|_{\text{MS}} = \left[ -\frac{\alpha}{\pi} \right] \left( 3\langle e^4 \rangle - \langle e^2 \rangle^2 \right) N_f \quad (4.17)
\]

On the other hand, in the \( \overline{\text{MS}} \) (and also in DIS) we obtain from Eq.\((2.5)\)

\[
\Delta A_{\psi, n=1}^{\psi, a} = -12\langle e^2 \rangle N_f \quad (4.18)
\]

\[
\Delta A_{NS, n=1}^{\psi, a} = -12\left( \langle e^4 \rangle - \langle e^2 \rangle^2 \right) N_f \quad (4.19)
\]

and thus \( \Delta q^\gamma_S(n=1) \bigg|_{\text{MS}} \) and \( \Delta q^\gamma_{NS, n=1} \bigg|_{\text{MS}} \) are non-zero constant. Actually we can go one step further to the order of \( \alpha_s \) QCD corrections. This is due to the fact that, in the \( \overline{\text{MS}} \) scheme, the parton distribution \( \Delta q^\gamma_S(n=1) \bigg|_{\text{MS}} = (\Delta g^\gamma_S, \Delta G^\gamma, \Delta q^\gamma_{NS}) \bigg|_{\text{MS}} \) satisfies a homogeneous differential equation without inhomogeneous LO and NLO \( \Delta K \) terms. Indeed we find

\[
\Delta q_S^\gamma(n = 1, Q^2, P^2) \bigg|_{\overline{\text{MS}}} = \left[ -\frac{\alpha}{\pi} \right] \left( 3\langle e^2 \rangle N_f \right) \left\{ 1 - \frac{2\alpha_s(P^2) - \alpha_s(Q^2)}{\beta_0} \right\} N_f \quad (4.20)
\]

\[
\Delta q_{NS}^\gamma(n = 1, Q^2, P^2) \bigg|_{\overline{\text{MS}}} = \left[ -\frac{\alpha}{\pi} \right] \left( 3\langle e^4 \rangle - \langle e^2 \rangle^2 \right) N_f \left\{ 1 + \mathcal{O}(\alpha_s^2) \right\} \quad (4.21)
\]

the derivation of which is shown in Appendix C. In the \( \overline{\text{MS}} \) scheme, the axial anomaly effects are retained in the quark distributions. The factors \( \left[ -\frac{\alpha}{\pi} \right] \left( 3\langle e^2 \rangle N_f \right) \) and \( \left[ -\frac{\alpha}{\pi} \right] \left( 3\langle e^4 \rangle - \langle e^2 \rangle^2 \right) N_f \) are related to the QED axial anomaly and a term \( \frac{2}{\beta_0} \frac{\alpha_s(P^2) - \alpha_s(Q^2)}{\pi} N_f \) in \( \Delta q^\gamma_S(n=1) \bigg|_{\text{MS}} \) is coming from the QCD axial anomaly.
4.3 The $n = 1$ moment of $g_1^\gamma(x, Q^2, P^2)$

The polarized structure function $g_1^\gamma(x, Q^2, P^2)$ of the virtual photon satisfies the following sum rule\[20, 23\]:

$$\int_0^1 dx g_1^\gamma(x, Q^2, P^2) = -\frac{3\alpha}{\pi} \langle e^4 \rangle N_f \left( 1 - \frac{\alpha_s(Q^2)}{\pi} \right)$$

$$+ \frac{6\alpha}{\pi \beta_0} \left[ \langle e^2 \rangle N_f \right]^2 \frac{\alpha_s(P^2) - \alpha_s(Q^2)}{\pi} + O(\alpha_s^2).$$

This sum rule is of course the factorization-scheme independent. Now we examine how the scheme-dependent parton distributions contribute to this sum rule. In the CI-like schemes ($a = CI, AB, OS, AR$), the first moment of the quark distributions vanish in NLO, and thus the contribution to the sum rule comes from the gluon and photon distributions. Equations (4.6) and (4.15) show that

$$\Delta C_{\gamma, n=1}^{G, a} \Delta G(n = 1, Q^2, P^2)|_a + \Delta C_{\gamma, n=1}^{\gamma, a}$$

leads to the result (4.22). On the other hand, in the $\overline{\text{MS}}$ scheme (and also in DIS), the one-loop gluon and photon coefficient functions vanish, $\Delta B_{\gamma, n=1}^{G, \overline{\text{MS}}} = \Delta B_{\gamma, n=1}^{\overline{\text{MS}}}$ = 0 and, therefore, the sum rule is derived from the quark contributions. Indeed we find from Eqs.(4.16), (4.20-4.21)

$$\Delta C_{\gamma, n=1}^{\gamma, S, \overline{\text{MS}}} \Delta q_\gamma(n = 1, Q^2, P^2)|_{\overline{\text{MS}}} + \Delta C_{\gamma, n=1}^{\gamma, N, S, \overline{\text{MS}}} \Delta q_{\gamma, N, S}(n = 1, Q^2, P^2)|_{\overline{\text{MS}}}$$

leads to the same result.

It is interesting to note that the sum rule (4.22) is the consequence of the QCD and QED axial anomalies and that in the CI-like schemes the anomaly effect resides in the gluon contribution while, in $\overline{\text{MS}}$, in the quark contributions. Furthermore, the first term of the sum rule (4.22) is coming from the QED axial anomaly and the second is from the QCD axial anomaly\[1\].

5 Behaviors of parton distributions near $x = 1$

The behaviors of parton distributions near $x = 1$ are governed by the large-$n$ limit of those moments. In the leading order, parton distributions are factorization-scheme

---

1

This notion was first pointed out by the authors of Ref.\[20\]
independent. For large \( n \), \( \Delta q_S^\gamma(n, Q^2, P^2)|_{LO} \) and \( \Delta q_S^{\gamma S}(n, Q^2, P^2)|_{LO} \) behave as \( 1/(n \ln n) \), while \( \Delta G^\gamma(n, Q^2, P^2)|_{LO} \propto 1/(n \ln n)^2 \). Thus in \( x \) space, the parton distributions vanish for \( x \to 1 \). In fact, we find
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{LO} \approx \frac{\alpha}{4\pi} \frac{4\pi}{\alpha_s(Q^2)} N_f \langle e^2 \rangle \frac{9}{4} \frac{-1}{\ln (1-x)}, \quad (5.1)
\]
\[
\Delta G^\gamma(x, Q^2, P^2)|_{LO} \approx \frac{\alpha}{4\pi} \frac{4\pi}{\alpha_s(Q^2)} N_f \langle e^2 \rangle \frac{1}{2} \frac{-\ln x}{\ln^2 (1-x)}. \quad (5.2)
\]
The behaviors of \( \Delta q_S^{\gamma S}(x, Q^2, P^2) \) for \( x \to 1 \), both in LO and NLO, are always given by the corresponding expressions for \( \Delta q_S^\gamma(x, Q^2, P^2) \) with replacement of the charge factor \( \langle e^2 \rangle \) with \( \langle \langle e^4 \rangle - \langle e^2 \rangle^2 \rangle \).

In the \( \overline{\text{MS}} \) scheme, the moments of the NLO parton distributions are written in large \( n \) limit as
\[
\Delta q_S^\gamma(n, Q^2, P^2)|_{NLO, \overline{\text{MS}}} \rightarrow \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 6 \frac{\ln n}{n}, \quad (5.3)
\]
\[
\Delta G^\gamma(n, Q^2, P^2)|_{NLO, \overline{\text{MS}}} \rightarrow \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 3 \frac{1}{n^2}. \quad (5.4)
\]
So we have near \( x = 1 \)
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{NLO, \overline{\text{MS}}} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 6 \left[ -\ln(1-x) \right], \quad (5.5)
\]
\[
\Delta G^\gamma(x, Q^2, P^2)|_{NLO, \overline{\text{MS}}} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 3 \left[ -\ln x \right]. \quad (5.6)
\]
It is remarkable that, in the \( \overline{\text{MS}} \) scheme, quark parton distributions, \( \Delta q_S^\gamma(x)|_{NLO, \overline{\text{MS}}} \) and \( \Delta q_S^{\gamma S}(x)|_{NLO, \overline{\text{MS}}} \) positively diverge as \( [-\ln(1-x)] \) for \( x \to 1 \). Recall that \( \Delta G^\gamma(x, Q^2, P^2)|_{NLO} \) is the same among the schemes which we consider in this paper.

The NLO quark distributions in the CI, AB, AR and DIS\( ^\gamma \) schemes also diverge as \( x \to 1 \), since their moments behave as \( \ln n/n \) in the large \( n \)-limit. We find for large \( x \),
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{NLO, CI} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 6 \left[ -\ln(1-x) \right], \quad (5.7)
\]
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{NLO, AB} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 6 \left[ -\ln(1-x) + 2 \right], \quad (5.8)
\]
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{NLO, AR} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 18 \left[ -\ln(1-x) \right], \quad (5.9)
\]
\[
\Delta q_S^\gamma(x, Q^2, P^2)|_{NLO, DIS\gamma} \approx \frac{\alpha}{4\pi} N_f \langle e^2 \rangle 6 \ln(1-x). \quad (5.10)
\]
It is noted that $\Delta q^\gamma_S(x, Q^2, P^2)|_{\text{NLO, DIS}, \overline{\text{MS}}}$, negatively diverges as $x \to 1$. This is due to the fact that the photonic coefficient function $\Delta C^\gamma_{\gamma}(x)$, which in $\overline{\text{MS}}$ becomes negative and divergent for $x \to 1$, is absorbed into the quark distributions in the DIS$_\gamma$ scheme.

On the other hand, the OS scheme gives quite different behaviors near $x = 1$ for the quark distributions. Since the typical two-loop anomalous dimensions in the OS scheme behave in the large $n$-limit as

$$\Delta \gamma_{\text{NS, OS}}^{(1), n} \sim \Delta \gamma_{\text{qq, OS}}^{(1), n} \propto \ln^2 n, \quad \Delta K_{S, \text{OS}}^{(1), n} \propto \frac{\ln n}{n},$$

(5.11)

while in the $\overline{\text{MS}}$ scheme

$$\Delta \gamma_{\text{NS, MS}}^{(1), n} \sim \Delta \gamma_{\text{qq, MS}}^{(1), n} \propto \ln n, \quad \Delta K_{S, \text{MS}}^{(1), n} \propto \frac{\ln^2 n}{n},$$

(5.12)

we find that the moment of $\Delta q^\gamma_S(n, Q^2, P^2)|_{\text{NLO}}$ in the OS scheme is expressed in the large $n$-limit as

$$\Delta q^\gamma_S(n, Q^2, P^2)|_{\text{NLO, OS}} \rightarrow \frac{\alpha}{4\pi} N_f \left\langle e^2 \right\rangle \left[ \frac{69}{8} + \frac{3}{4} N_f \right] \frac{1}{n}$$

(5.13)

In $x$ space, $\Delta q^\gamma_S(x, Q^2, P^2)|_{\text{NLO, OS}}$ does not diverge for $x \to 1$ but approaches a constant value:

$$\Delta q^\gamma_S(x, Q^2, P^2)|_{\text{NLO, OS}} \rightarrow \frac{\alpha}{4\pi} N_f \left\langle e^2 \right\rangle \left[ \frac{69}{8} + \frac{3}{4} N_f \right].$$

(5.14)

Therefore, as far as the large $x$-behaviors of quark distributions, and gluon and photon coefficient functions (see Eqs. (5.18-5.19) below) are concerned, the OS scheme is more appropriate than other schemes in the sense that they remain finite. Also the quark coefficient function in the OS scheme has a milder divergence for $x \to 1$ than those predicted in other schemes (see Eq. (5.17)).

Before ending this section, we now show that, as $x \to 1$, the polarized virtual photon structure function $g_1^\gamma(x, Q^2, P^2)$ approaches a constant value

$$\kappa = \frac{\alpha}{4\pi} N_f \left\langle e^4 \right\rangle \left[ -\frac{51}{8} + \frac{3}{4} N_f \right],$$

(5.15)

in NLO. The result is, of course, factorization-scheme independent. It is interesting to note that the constant value $\kappa$ coincides exactly with the one given in Eq. (4.39)
of Ref.\[55\], which was derived as the large $n$ limit of the moment of the NLO term $b_2(x)$ for the unpolarized structure function $F_2^\gamma$. In the leading order, Eq.(5.1) tells us that

$$g_1^\gamma(x, Q^2, P^2)|_{\text{LO}} = \langle e^2 \rangle \Delta q_5^\gamma(x, Q^2, P^2)|_{\text{LO}} + \Delta q_{NS}^\gamma(x, Q^2, P^2)|_{\text{LO}}$$

and thus $g_1^\gamma(x, Q^2, P^2)|_{\text{LO}}$ vanishes as $x \to 1$.

In order to analyze the large $x$-behavior of the next-leading order $g_1^\gamma(x, Q^2, P^2)|_{\text{NLO}}$, we need information on the coefficient functions. Note that $\Delta B_n^\gamma|_{a} = \Delta B_n^\gamma|_{a}$. They behave, as $x \to 1$,

$$\Delta B_S(x)|_a \to \begin{cases} 
2C_F \left[ \frac{2 \ln(1-x)}{1-x} \right] & \text{for } a = \overline{\text{MS}}, \text{ CI, AB, DIS}_\gamma , \\
-2C_F \left[ \frac{2 \ln(1-x)}{1-x} \right] & \text{for } a = \text{AR} , \\
3C_F \left[ \frac{1}{(1-x)^2} \right] & \text{for } a = \text{OS} ,
\end{cases} \tag{5.17}
$$

$$\Delta B_G(x)|_a \to \begin{cases} 
2N_f \ln(1-x) & \text{for } a = \overline{\text{MS}}, \text{ CI, AB, AR, DIS}_\gamma , \\
-4N_f & \text{for } a = \text{OS} , \\
\frac{\alpha}{4 \pi} \langle e^4 \rangle 12N_f \ln(1-x) & \text{for } a = \overline{\text{MS}}, \text{ CI, AB, AR} , \\
-\frac{\alpha}{4 \pi} \langle e^4 \rangle 24N_f & \text{for } a = \text{OS} , \\
0 & \text{for } a = \text{DIS}_\gamma .
\end{cases} \tag{5.18}
$$

The coefficient functions $\Delta B_S(x)$ and $\Delta B_G(x)$ are the same that appear in the polarized nucleon structure function $g_1(x, Q^2)$. The $\Delta B_S(x)$ in all schemes considered here diverges as $x \to 1$, but OS scheme gives a milder divergence for $\Delta B_S(x)$ than other schemes. Also note that $\Delta B_G(x)|_{\text{OS}}$ remains finite as $x \to 1$, but $\Delta B_G(x)$ in other schemes negatively diverge.

Let us write $g_1^\gamma(x, Q^2, P^2)|_{\text{NLO}}$ in terms of partonic contributions as follows:

$$g_1^\gamma(x, Q^2, P^2)|_{\text{NLO}} = g_1^\gamma(x)|_{\text{NLO}}^{\text{quark}} + g_1^\gamma(x)|_{\text{NLO}}^{\text{gluon}} + \Delta C_\gamma^\gamma(x) , \tag{5.20}$$

21
where
\[
\begin{align*}
g_1^\gamma(x)|_{\text{NLO}}^{\text{quark}} & = \langle e^2 \rangle \Delta q_S^\gamma(x, Q^2, P^2)_{\text{NLO}} + \Delta q_{NS}^\gamma(x, Q^2, P^2)_{\text{NLO}} \\
& + \langle e^2 \rangle \frac{\alpha_s(Q^2)}{4\pi} \Delta B_S(x) \otimes \Delta q_S^\gamma(x, Q^2, P^2)_{\text{LO}} \\
& + \frac{\alpha_s(Q^2)}{4\pi} \Delta B_{NS}(x) \otimes \Delta q_{NS}^\gamma(x, Q^2, P^2)_{\text{LO}}, \\
g_1^\gamma(x)|_{\text{NLO}}^{\text{gluon}} & = \langle e^2 \rangle \frac{\alpha_s(Q^2)}{4\pi} \Delta B_G(x) \otimes \Delta G^\gamma(x, Q^2, P^2)_{\text{LO}}.
\end{align*}
\]

Then we find, for \( x \rightarrow 1, \)
\[
g_1^\gamma(x)|_{\text{NLO}}^{\text{quark}} \rightarrow \begin{cases} -\frac{\alpha_s(Q^2)}{4\pi} \langle e^4 \rangle 12N_f \ln(1-x) & \text{for } a = \overline{\text{MS}}, \text{ CI, AB, AR} , \\ \frac{\alpha_s(Q^2)}{4\pi} \langle e^4 \rangle N_f \left[ \frac{111}{8} + \frac{3}{4}N_f \right] & \text{for } a = \text{OS} , \\ \frac{\alpha_s(Q^2)}{4\pi} \langle e^4 \rangle N_f \left[ -\frac{51}{8} + \frac{3}{4}N_f \right] & \text{for } a = \text{DIS}_\gamma , \\ \end{cases}
\]

The NLO gluon contribution \( g_1^\gamma(x, Q^2, P^2)|_{\text{NLO}}^{\text{gluon}} \) vanishes faster than \((\ln x)^2\) in any scheme under consideration. As for the NLO quark contribution, \( g_1^\gamma(x, Q^2, P^2)|_{\text{NLO}}^{\text{quark}} \) in \( \overline{\text{MS}}, \text{ CI, AB, AR} \) schemes, diverges as \([-\ln(1-x)]\) for \( x \rightarrow 1 \). However, Eq.(5.19) shows that the one-loop photon coefficient function \( \Delta C_\gamma^\gamma(x) \) in these schemes also diverges as \([-\ln(1-x)]\) with the opposite sign and the sum becomes finite. On the other hand, in the OS scheme, we observe from Eqs.(5.23) and (5.19) that both the quark contribution and photon coefficient function remain finite as \( x \rightarrow 1 \), and it is easily seen that the sum
\[
g_1^\gamma(x)|_{\text{NLO}, \text{OS}}^{\text{quark}} + \Delta C(x)|_{\gamma, \text{OS}}^\gamma
\]
approaches the constant value \( \kappa \) given in Eq.(5.15). In the DIS\(_\gamma\) scheme, the NLO quark contribution \( g_1^\gamma(x)|_{\text{NLO, DIS}}^{\text{quark}} \) reaches the finite value \( \kappa \) as \( x \rightarrow 1 \), since \( \Delta C(x)|_{\gamma, \text{DIS}_\gamma}^\gamma \equiv 0 \). In fact, as we see from Eq.(5.24), \( g_1^\gamma(x)|_{\text{NLO}}^{\text{quark}} \) is made up of two parts, the one from \( \Delta q_S^\gamma(x, Q^2, P^2)|_{\text{NLO}} \) and the other from \( \Delta B_S(x) \otimes \Delta q_S^\gamma(x, Q^2, P^2)|_{\text{LO}} \), plus their non-singlet quark counterparts. In DIS\(_\gamma\), both contributions diverge as \( x \rightarrow 1 \), but with the opposite sign, and the sum remains finite.

The constant value \( \kappa \) in Eq.(5.15) is negative unless \( N_f \geq 9 \). Consequently, it seems superficially that QCD with 8 flavors or less predicts that the structure...
function $g_\gamma^1(x, Q^2, P^2)$ turns out to be negative for $x$ very close to 1, since the leading term $g_\gamma^1(x, Q^2, P^2)|_{LO}$ vanishes as $x \to 1$. But the fact is that $x$ cannot reach exactly one. The constraint $(p+q)^2 \geq 0$ gives

$$x \leq x_{\max} = \frac{Q^2}{Q^2 + P^2},$$

(5.25)

and we find

$$g_\gamma^1(x = x_{\max}, Q^2, P^2)|_{LO} > \frac{\alpha}{4\pi} N_f \langle e^4 \rangle \frac{3}{C_F} \beta_0$$

(5.26)

and the sum $g_\gamma^1(x = x_{\max}, Q^2, P^2)|_{LO+NLO}$ is indeed positive.

6 Numerical analysis

The parton distribution functions are recovered from the moments by the inverse Mellin transformation. In Fig. 2 we plot the factorization scheme dependence of the singlet quark distribution $\Delta q_S^\gamma(x, Q^2, P^2)$ beyond the LO in units of $(3N_f \langle e^2 \rangle \alpha/\pi) \ln(Q^2/P^2)$. We have taken $N_f = 3$, $Q^2 = 30$ GeV$^2$, $P^2 = 1$ GeV$^2$, and the QCD scale parameter $\Lambda = 0.2$ GeV. All four CI-like (i.e., CI, AB, OS and AR) curves cross the $x$-axis nearly at the same point, just below $x = 0.5$, while the $\overline{\text{MS}}$ curve crosses at above $x = 0.5$. This is understandable since we saw from Eqs.(4.13, 4.20) that the first moment of $\Delta q_S^\gamma$ vanishes in the CI-like schemes while it is negative in the $\overline{\text{MS}}$ scheme. The DIS$^\gamma$ curve crosses the $x$-axis below $x = 0.5$, though the first moment of $\Delta q_S^\gamma|_{DIS}$ is negative, taking the same value with the one in the $\overline{\text{MS}}$ scheme. Comparing the DIS$^\gamma$ curve at large $x$ with the $\overline{\text{MS}}$ one, we will see that rapid dropping of the DIS$^\gamma$ curve as $x \to 1$ drives the crossing point below $x = 0.5$.

As $x \to 1$, we observe that the $\overline{\text{MS}}$, CI, AB, and AR curves continue to increase. In fact we see that the $\overline{\text{MS}}$ and CI curves tend to merge, the AB curve comes above those two curves and the AR curve diverges more rapidly than the other three. On the other hand, the OS and DIS$^\gamma$ curves start to drop at large $x$. The OS curve continues to increase till near $x = 1$, and then starts to drop to reach a finite positive value. The DIS$^\gamma$ curve reaches maximum at $x \approx 0.8$ and drops to negative values. These behaviors are inferred from Eqs.(5.5, 5.7-5.10, 5.14).
Concerning the non-singlet quark distribution $\Delta q_{NS}(x,Q^2,P^2)$, we find that when we take into account the charge factors, it falls on the singlet quark distribution in almost all $x$ region; namely two “normalized” distributions $\Delta \tilde{q}^\gamma_S \equiv \Delta q^\gamma_S / \langle e^2 \rangle$ and $\Delta \tilde{q}^\gamma_{NS} \equiv \Delta q^\gamma_{NS} / (\langle e^4 \rangle - \langle e^2 \rangle^2)$ mostly overlap except at very small $x$ region. The situation is the same in all factorization schemes we have studied in this paper. This is attributable to the fact that once the charge factors are taken into account, the evolution equations for both $\Delta \tilde{q}^\gamma_S$ and $\Delta \tilde{q}^\gamma_{NS}$ have the same inhomogeneous LO and NLO $\Delta K$ terms and the same initial conditions at $Q^2 = P^2$ (see Eq.(3.20)).

In Fig. 3 we plot again the OS and DIS$\gamma$ predictions for $\Delta q^\gamma_S(x,Q^2,P^2)$ together with the LO result. The motivation of having introduced DIS$\gamma$ scheme into the analysis of the unpolarized (polarized) real photon structure function $F^\gamma_2(g^\gamma_1)$ was to reduce the discrepancies at large-$x$ region between the LO and the NLO results for the ‘pointlike’ part of $F^\gamma_2(g^\gamma_1)$. When applied to the polarized virtual photon case, it is seen from Fig. 2 and 3 that DIS$\gamma$ scheme gives a better behavior for $\Delta q^\gamma_S(x,Q^2,P^2)$ at large $x$ than $\overline{\text{MS}}$ in the sense that DIS$\gamma$ curve is closer to the LO result. However, we observe that absorbing the photonic coefficient function $\Delta C^\gamma_2$ into the quark distributions in the DIS$\gamma$ scheme has too much effect on their large-$x$ behaviors: The DIS$\gamma$ curve for $\Delta q^\gamma_S(x,Q^2,P^2)$ goes under the LO one at $x \approx 0.6$ and the difference between the two grows as $x \to 1$. In fact the DIS$\gamma$ curve drops to negative values near at $x = 1$.

From the viewpoint of ‘perturbative stabilities’ we find that the OS curve shows more appropriate behavior than the others. We see from Fig. 3 that the differences between the OS and LO curves are very small for the range $0.05 < x < 0.7$. And the OS curve comes above the LO for $x > 0.7$.

Fig. 4 shows the $Q^2$-dependence of $\Delta q^\gamma_S(x,Q^2,P^2)$ in the OS scheme in units of $(3N_f(e^2)\alpha/\pi)\ln(Q^2/P^2)$. Three curves with $Q^2 = 30$, 50 and 100 GeV$^2$ almost overlap in whole $x$ region except in the vicinity of $x = 1$. We see from Fig. 4 that, in the OS scheme, $\Delta q^\gamma_S$ beyond the LO behaves approximately as the one obtained from the box (tree) diagram calculation,

$$\Delta q^\gamma_S^{(\text{Box})}(x,Q^2,P^2) = (2x - 1)3N_f(e^2)\frac{\alpha}{\pi} \ln \frac{Q^2}{P^2}.$$  \hspace{1cm} (6.1)

The gluon distribution $\Delta G^\gamma(x,Q^2,P^2)$ beyond the LO is shown in Fig. 5 in units
of \((3N_f(e^2)\alpha/\pi)\ln(Q^2/P^2)\), with three different \(Q^2\) values. Recall that every scheme considered in this paper predicts the same behavior for the gluon distribution up to NLO. We do not see much difference in three curves with different \(Q^2\). This means the \(\Delta G^\gamma\) is approximately proportional to \(\ln(Q^2/P^2)\). But, compared with quark distributions, \(\Delta G^\gamma\) is very much small in absolute value except at the small \(x\) region.

In Fig. 6 we plot the virtual photon structure function \(g_1^\gamma(x, Q^2, P^2)\) in the NLO for \(N_f = 3, Q^2 = 30\text{ GeV}^2\) and \(P^2 = 1\text{ GeV}^2\) and the QCD scale parameter \(\Lambda = 0.2\text{ GeV}^2\). The vertical axis corresponds to

\[
g_1^\gamma(x, Q^2, P^2)\frac{3\alpha}{\pi} N_f < e^4 > \ln \frac{Q^2}{P^2}. \tag{6.2}
\]

Also shown are the LO result, the Box (tree) diagram contribution,

\[
g_1^{\text{Box}}(x, Q^2, P^2) = (2x - 1)\frac{3\alpha}{\pi} N_f < e^4 > \ln \frac{Q^2}{P^2} , \tag{6.3}
\]

and the Box diagram contribution including non-leading (NL) correction with mass being ignored

\[
g_1^{\text{Box(NL)}}(x, Q^2, P^2) = \frac{3\alpha}{\pi} N_f < e^4 > \left[ (2x - 1) \ln \frac{Q^2}{P^2} - 2(2x - 1)(\ln x + 1) \right]. \tag{6.4}
\]

In our previous paper [23], there was an error in the program for numerical evaluation of the NLO \(g_1^\gamma(x, Q^2, P^2)\). The corrected graph (NLO curve) here is different from the corresponding one in Fig.2 of Ref. [23]. The new NLO curve appears lower than the previous one for \(x < 0.7\) and rather enhanced above \(x = 0.7\). We observe that the corrected NLO curve remains below the LO one, and that the NLO QCD corrections are significant at large \(x\) as well as at low \(x\).

For the case of the real photon target, \(P^2 = 0\), the structure function can be decomposed as

\[
g_1^\gamma(x, Q^2) = g_1^\gamma(x, Q^2)|_{\text{pert.}} + g_1^\gamma(x, Q^2)|_{\text{non-pert.}} . \tag{6.5}
\]

The first term, the point-like piece, can be calculated in a perturbative method. Actually, it can be obtained by setting \(P^2 = \Lambda^2\) in the expressions of parton distributions in Eq.(2.2) or (2.3). The second term can only be computed by some
non-perturbative methods. In Fig. 7, we plot the point-like piece of the real photon $g_1^\gamma(x, Q^2)$ in the NLO, together with the LO result and the Box (tree) diagram contribution. The NLO curve, which is calculated by the corrected computer program, is different from the previous one in Fig. 6 in ref. [23]. The new NLO curve appears lower than the previous one for $x < 0.6$ and enhanced above $x = 0.6$. Also it remains below the LO curve. The NLO result qualitatively consistent with the analysis by Stratmann and Vogelsang [18]. In the unpolarized case, the moment of $F_2^\gamma$ has a singularity at $n = 2$ which leads to the negative structure function at low $x$. Thus we need some regularization prescription to recover positive structure function as discussed in Refs. [56, 57, 58]. Note that we do not have such complication at $n = 1$ for the polarized case.

Finally, in our numerical analysis, we took $P^2 = 1\text{GeV}^2$, which may not be necessarily large enough for the non-perturbative effects to be dying away. For our normalized parton distributions, however, the larger values of $P^2$ would not give any sizable change in shape and magnitude.

7 Conclusion

In the present paper, we have studied in detail the spin-dependent parton distributions inside the virtual photon, which can be predicted entirely up to NLO in perturbative QCD. The virtual photon target provides a good testing ground for examining the factorization scheme dependence of the quark and gluon distributions. We have investigated the polarized parton distributions in several different factorization schemes. We derived the explicit transformation rules from one scheme to another for the coefficient functions, the finite photon matrix elements and the two-loop anomalous dimensions or parton splitting functions.

In particular, we studied the QCD and QED axial anomaly effects on the first moments of quark distributions to see the interplay between the axial anomalies and factorization schemes. We find that, in the CI-like schemes, the first moments of polarized quark distributions, both flavor singlet and non-singlet, vanish in NLO while the standard $\overline{\text{MS}}$ scheme gives the non-zero value. Also we find that the large $x$-behaviors of polarized quark distributions dramatically vary from one factorization
scheme to another. Indeed, for $x \to 1$, the quark distributions positively diverge or negatively diverge or remain finite, depending on factorization schemes. The numerical analyses performed for the parton distributions reassures the above observations. From the viewpoint of ‘perturbative stabilities’ the OS scheme gives more appropriate behaviors for the quark distributions than the others. The gluon distribution turns out to be the same up to NLO among the six factorization schemes examined. Furthermore, its first moment is found to be factorization-scheme independent up to NLO.

The same analysis on the factorization scheme dependence of the unpolarized parton distributions of the virtual photon can be carried out and will be discussed elsewhere.

Riemann for the hospitality extended to him at the 5th Zeuthen Workshop “Loops and Legs 2000”. Some of the results in this paper have been reported at the workshop. We also thank E. Reya and C. Sieg for the communication regarding the numerical evaluation of the structure function. This work is partially supported by the Monbusho Grant-in-Aid for Scientific Research NO.(C)(2)-12640266.
Appendix

A NLO expressions for polarized parton distributions in the virtual photon

We give the explicit expressions of $\Delta q_S^2$, $\Delta G^\gamma$, and $\Delta q_{NS}^2$ up to NLO. They are written in terms of one-(two-) loop anomalous dimensions $\Delta \gamma_{ij}^{0,n}$ ($\Delta \gamma_{ij}^{(1),n}$) ($i,j = \psi, G$), $\Delta \gamma_{NS}^{0,n}$ ($\Delta \gamma_{NS}^{(1),n}$), $\Delta K_l^{0,n}$ ($\Delta K_l^{(1),n}$) ($l = \psi, G, NS$), and the one-loop photon matrix elements of hadronic operators, $\Delta A_{\psi}^n$. The expressions of one-loop and $\overline{\text{MS}}$ scheme-two-loop anomalous dimensions are found, for example, in Appendix of Ref. [23].

A.1 Singlet quark distribution

$$
\Delta q_S^2(n, Q^2, P^2) = \frac{\alpha}{8\pi\beta_0} \cdot \hat{L}_S^{\pm n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_+^n/2\beta_0 + 1} \right\} + \frac{4\pi}{\alpha_s(Q^2)} \hat{L}_S^{-n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_-^n/2\beta_0 + 1} \right\}
$$

$$
\hat{A}_S^{+ n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_+^n/2\beta_0} \right\} + \hat{A}_S^{- n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_-^n/2\beta_0} \right\}
$$

$$
\hat{B}_S^{+ n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_+^n/2\beta_0 + 1} \right\} + \hat{B}_S^{- n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_-^n/2\beta_0 + 1} \right\}
$$

$$
\hat{C}_S^n
$$

A.2 Gluon distribution

\[ \Delta G^\gamma(n, Q^2, P^2) / \frac{\alpha}{8\pi\beta_0} \]

\[ = \frac{4\pi}{\alpha_s(Q^2)} \hat{L}^+_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} + \frac{4\pi}{\alpha_s(Q^2)} \hat{L}^-_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} \]

\[ + \hat{A}^+_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} + \hat{A}^-_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} \]

\[ + \hat{B}^+_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} + \hat{B}^-_{G^n} \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda^n_n/2\beta_0 + 1} \right\} \]

where

\[ \hat{L}^+_{G^n} = \frac{\Delta K^0, n}{\lambda^n_+ - \lambda^n_n} / \frac{1}{1 + \lambda^n_+/2\beta_0} \]

\[ \hat{L}^-_{G^n} = \frac{\Delta K^0, n}{\lambda^n_n - \lambda^n_+} / \frac{1}{1 + \lambda^n_/2\beta_0} \]

and

\[ \hat{A}^+_{G^n} = \frac{1}{\lambda^n_+(\lambda^n_+ - \lambda^n_n)(2\beta_0 + \lambda^n_n - \lambda^n_+)} \]

\[ \times \left( \Delta K^0, n \left\{ (\Delta \gamma^0, n - 2\beta_0 - \lambda^n_n) \Delta \gamma^{(1), n} + \Delta \gamma^0, n \Delta \gamma^{(1), n}_G \right\} \Delta \gamma^0, n \right. \]

\[ + \Delta K^0, n \left\{ (\Delta \gamma^0, n - 2\beta_0 - \lambda^n_n) \Delta \gamma^{(1), n} + \Delta \gamma^0, n \Delta \gamma^{(1), n}_G \right\} (\Delta \gamma^0, n - \lambda^n_-) \]

\[ + 2\beta_0(2\beta_0 + \lambda^n_n - \lambda^n_+) \left\{ \Delta K^{(1), n}_G \Delta \gamma^0, n + \Delta K^{(1), n}_G (\Delta \gamma^0, n - \lambda^n_-) \right\} \]

\[ - 2\beta_0(2\beta_0 + \lambda^n_n - \lambda^n_+) \lambda^n_+ \Delta A^0, n \Delta \gamma^0, n \]

\[ \left. - \frac{\beta_1}{\beta_0} \Delta K^0, n (2\beta_0 + \lambda^n_n - \lambda^n_+) (2\beta_0 - \lambda^n_+) \Delta \gamma^0, n \right) \]

(A.12)

\[ \hat{B}^+_{G^n} \]
\[ \hat{A}_{G}^{-n} = \frac{1}{\lambda^n - \lambda_+^n}(2\beta_0 + \lambda_+^n - \lambda^n) \times \frac{1}{\lambda^n - \lambda_+^n}(2\beta_0 + \lambda_+^n - \lambda^n) \times \left\{ \begin{array}{l} (\Delta \gamma_{G\psi}^{-1}, n) \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \end{array} \right\} \Delta \gamma_{G\psi}^{-1} \\
+ \Delta K^0_n \left\{ (\Delta \gamma_{G\psi}^{-1} - 2\beta_0 - \lambda_n^+ \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \right\} (\Delta \gamma_{G\psi}^{-1} - \lambda_+^n) \\
+ 2\beta_0 (2\beta_0 + \lambda_+^n - \lambda_-^n) \left\{ \Delta K^0_n + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} (\Delta \gamma_{G\psi}^{-1} - \lambda_+^n) \right\} \\
- \frac{\beta_1}{\beta_0} \Delta \gamma_{G\psi}^{-1} (2\beta_0 + \lambda_+^n - \lambda_-^n)(2\beta_0 - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} \right\} \] (A.14)

\[ \hat{B}_{G}^{+n} = \Delta K^0_n \times \frac{1}{(2\beta_0 + \lambda_+^n)(2\beta_0 + \lambda_+^n - \lambda^n)} \times \left\{ \begin{array}{l} (\Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \end{array} \right\} (2\beta_0 + \Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \\
+ \left\{ (\Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \right\} \Delta \gamma_{G\psi}^{-1} \\
- \frac{\beta_1}{\beta_0} (2\beta_0 + \lambda_+^n - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} \right\} \] (A.15)

\[ \hat{B}_{G}^{-n} = \Delta K^0_n \times \frac{1}{(2\beta_0 + \lambda_+^n)(2\beta_0 + \lambda_+^n - \lambda_-^n)} \times \left\{ \begin{array}{l} (\Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \end{array} \right\} (2\beta_0 + \Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \\
+ \left\{ (\Delta \gamma_{G\psi}^{-1} - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} + \Delta \gamma_{G\psi}^{-1} \Delta \gamma_{G\psi}^{-1} \right\} \Delta \gamma_{G\psi}^{-1} \\
- \frac{\beta_1}{\beta_0} (2\beta_0 + \lambda_+^n - \lambda_-^n) \Delta \gamma_{G\psi}^{-1} \right\} \] (A.16)

### A.3 Non-singlet quark

\[ \Delta q_{NS}^n(n, Q^2, P^2)/{\alpha \over 8\pi \beta_0} = \frac{4\pi}{\alpha_s(Q^2)} \hat{L}_{NS}^n \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_n^\psi/2\beta_0 + 1} \right\} \\
+ \hat{A}_{NS}^n \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_n^\psi/2\beta_0} \right\} \]
\begin{align*}
+ \hat{B}^n_{NS} & \left\{ 1 - \left[ \frac{\alpha_s(Q^2)}{\alpha_s(P^2)} \right]^{\lambda_{NS}^n/2\beta_0 + 1} \right\} \\
+ \hat{C}^n_{NS}
\end{align*}

(\text{A.17})

where

\begin{align*}
\hat{L}^n_{NS} & = \Delta K^{0,n}_{NS} \cdot \frac{1}{1 + \lambda_{NS}^n/2\beta_0} \\
\hat{A}^n_{NS} & = \frac{1}{\lambda_{NS}} \left\{ -\Delta K^{0,n}_{NS} \Delta \gamma^{(1),n}_{NS} + 2\beta_0 \Delta K^{(1),n}_{NS} - 2\beta_0 \lambda_{NS}^n \Delta A_{NS}^n \right. \\
& \quad \left. - \frac{\beta_1}{\beta_0} \Delta K^{0,n}_{NS} (2\beta_0 - \lambda_{NS}^n) \right\} \\
\hat{B}^n_{NS} & = \Delta K^{0,n}_{NS} \frac{1}{2\beta_0 + \lambda_{NS}^n} \left( \Delta \gamma^{(1),n}_{NS} - \frac{\beta_1}{\beta_0} \lambda_{NS}^n \right) \\
\hat{C}^n_{NS} & = 2\beta_0 \Delta A_{NS}^n \\
\end{align*}

(A.18) - (A.21)

with

\begin{align*}
\lambda_{NS}^n & = \Delta \gamma_{NS}^0
\end{align*}

(A.22)

\section{The first moments}

\subsection{One-loop order}

\begin{align*}
\Delta \gamma_{NS}^{0,n=1} & = \Delta \gamma_{\psi\psi}^{0,n=1} = 0 \\
\Delta \gamma_{G\psi}^{0,n=1} & = 0, \quad \Delta \gamma_{G\psi}^{0,n=1} = -6C_F \\
\Delta \gamma_{GG}^{0,n=1} & = -\frac{22}{3}C_A + \frac{8}{3}T_f = -2\beta_0 \\
\lambda_{+}^{n=1} & = 0, \quad \lambda_{-}^{n=1} = -2\beta_0 \\
\Delta K_{NS}^{0,n=1} & = \Delta K_{\psi\psi}^{0,n=1} = 0
\end{align*}

(B.1) - (B.5)

where

\begin{align*}
C_A & = 3, \quad C_F = \frac{4}{3}, \quad T_f = \frac{N_f}{2}
\end{align*}

(B.6)

with \(N_f\) being the number of flavors.
B.2 MS scheme

\[ \Delta \gamma_{NS, \overline{MS}}^{(1), n=1} = 0 \] (B.7)

\[ \Delta \gamma_{\psi\psi, \overline{MS}}^{(1), n=1} = 24 C_F T_f \] (B.8)

\[ \Delta \gamma_{\psi G, \overline{MS}}^{(1), n=1} = 0 \] (B.9)

\[ \Delta \gamma_{G\psi, \overline{MS}}^{(1), n=1} = 18 C_F^2 - \frac{142}{3} C_A C_F + \frac{8}{3} C_F T_f \] (B.10)

\[ \Delta \gamma_{GG, \overline{MS}}^{(1), n=1} = 8 C_F T_f + \frac{40}{3} C_A T_f - \frac{68}{3} C_A^2 = -2 \beta_1 \] (B.11)

\[ \Delta \gamma_{\gamma, \overline{MS}}^{(1), n=1} = \Delta K_{G, \overline{MS}}^{(1), n=1} = \Delta K_{NS, \overline{MS}}^{(1), n=1} = 0 \] (B.12)

\[ \Delta A_{\psi, \overline{MS}}^{n=1} = -12 \langle e^2 \rangle N_f \] (B.13)

\[ \Delta A_{G, \overline{MS}}^{n=1} = 0 \] (B.14)

\[ \Delta A_{NS, \overline{MS}}^{n=1} = -12(\langle e^4 \rangle - \langle e^2 \rangle^2) N_f \] (B.15)

\[ \Delta B_{\psi, \overline{MS}}^{n=1} = \Delta B_{NS, \overline{MS}}^{n=1} = -3 C_F \] (B.16)

\[ \Delta B_{G, \overline{MS}}^{n=1} = \frac{N_f}{2} \Delta B_{\gamma, \overline{MS}}^{n=1} = 0 \] (B.17)

\[ \Delta B_{\psi, \overline{MS}}^{n=1} = \Delta B_{NS, \overline{MS}}^{n=1} = \Delta B_{\gamma, \overline{MS}}^{n=1} = 0 \] (B.18)

B.3 CI-like schemes (CI, AB, OS, AR)

\[ \Delta \gamma_{NS, a}^{(1), n=1} = 0 \] (B.19)

\[ \Delta \gamma_{\psi\psi, a}^{(1), n=1} = 0 \] (B.20)

\[ \Delta \gamma_{\psi G, a}^{(1), n=1} = \Delta \gamma_{\psi G, \overline{MS}}^{(1), n=1} = 0 \] (B.21)

\[ \Delta \gamma_{G\psi, a}^{(1), n=1} = \Delta \gamma_{G\psi, \overline{MS}}^{(1), n=1} = 18 C_F^2 - \frac{142}{3} C_A C_F + \frac{8}{3} C_F T_f \] (B.22)

\[ \Delta \gamma_{GG, a}^{(1), n=1} = 32 C_F T_f + \frac{40}{3} C_A T_f - \frac{68}{3} C_A^2 = -2 \beta_1 + 12 N_f C_F \] (B.23)
\[ \Delta K_{\psi, a}^{(1), n=1} = \Delta K_{NS, a}^{(1), n=1} = 0 \quad (B.24) \]
\[ \Delta K_{G, a}^{(1), n=1} = -72 \langle e^2 \rangle N_f C_F \quad (B.25) \]
\[ \Delta A_{\psi, a}^{n=1} = \Delta A_{G, a}^{n=1} = \Delta A_{NS, a}^{n=1} = 0 \quad (B.26) \]
\[ \Delta B_{\psi, a}^{n=1} = \Delta B_{NS, a}^{n=1} = -3 C_F \quad (B.27) \]
\[ \Delta B_{G, a}^{n=1} = \frac{N_f}{2} \Delta B_{\gamma, a}^{n=1} = -2 N_f \quad (B.28) \]

C Derivation of Eqs.(4.20) and (4.21)

We observe that, in the MS scheme, we have \( \Delta K^{0, n=1} = \Delta K^{(1), n=1} = 0 \), where \( \Delta K^n = (\Delta K_{\psi}^n, \Delta K_{G}^n, \Delta K_{NS}^n) \). (Note \( \Delta K_{G, c_{1\text{-like}}}^{(1), n=1} \neq 0 \). See Eq. (B.24).) Then, up to NLO, the parton distributions \( \Delta q^\gamma(n=1)|_{\overline{\text{MS}}} = (\Delta q_S^\gamma, \Delta G^\gamma, \Delta q_{\gamma NS}^\gamma)|_{\overline{\text{MS}}} \) satisfy a homogeneous differential equation instead of an inhomogenous one:

\[
\frac{d}{d \ln Q^2} \Delta q^\gamma(n=1, Q^2, P^2)|_{\overline{\text{MS}}} = \Delta q^\gamma(n=1, Q^2, P^2)|_{\overline{\text{MS}}} \Delta P(n=1, Q^2)|_{\overline{\text{MS}}} \quad (C.1)
\]

where the 3 \times 3 splitting function matrix \( \Delta P \) is the hadronic part of \( \Delta \tilde{P} \) given in Eq.(3.10). Expanding \( \Delta P(n=1, Q^2)|_{\overline{\text{MS}}} \) as

\[
\Delta P(n=1, Q^2)|_{\overline{\text{MS}}} = \frac{\alpha_s(Q^2)}{2\pi} \Delta P_{n=1}^{(0)} + \left[ \frac{\alpha_s(Q^2)}{2\pi} \right]^2 \Delta P_{n=1}^{(1)}|_{\overline{\text{MS}}} + \cdots, \quad (C.2)
\]

and introducing \( t \) instead of \( Q^2 \) as the evolution variable

\[
t \equiv \frac{2}{\beta_0} \ln \frac{\alpha_s(P^2)}{\alpha_s(Q^2)}, \quad (C.3)
\]

we find that Eq.(C.1) is rewritten as

\[
\frac{d}{dt} \Delta q^\gamma_{n=1}(t)|_{\overline{\text{MS}}} = \Delta q^\gamma_{n=1}(t)|_{\overline{\text{MS}}} \left\{ \Delta P_{n=1}^{(0)} + \frac{\alpha_s(t)}{2\pi} \left[ \Delta P_{n=1}^{(1)}|_{\overline{\text{MS}}} - \frac{\beta_1}{2\beta_0} \Delta P_{n=1}^{(0)} \right] + \mathcal{O}(\alpha_s^2) \right\}. \quad (C.4)
\]
We look for the solution in the following form:

\[ \Delta q_{n=1}^{\gamma}(t)_{\text{MS}} = \Delta q_{n=1}^{\gamma(0)}(t) + \Delta q_{n=1}^{\gamma(1)}(t)_{\text{MS}} \]  

with the initial condition (see Eq. (2.5)),

\[ \Delta q_{n=1}^{\gamma(0)}(0) = 0 \]  

\[ \Delta q_{n=1}^{\gamma(1)}(0)_{\text{MS}} = \frac{\alpha_s}{4\pi} \Delta A_{n=1|\text{MS}} \]

\[ = -\frac{3\alpha_s}{\pi} N_f \left( \langle e^2 \rangle , 0 , \langle e^4 \rangle - \langle e^2 \rangle^2 \right) \]

In the LO, we easily find that \( \Delta q_{n=1}^{\gamma(0)}(t) = 0 \) due to the initial condition (C.6).

The evolution equation in the NLO is written as

\[ \frac{d \Delta q_{n=1}^{\gamma(1)}(t)_{\text{MS}}}{dt} = \Delta q_{n=1}^{\gamma(1)}(t)_{\text{MS}} \left\{ \Delta P_{n=1}^{(0)} \left[ \Delta P_{n=1}^{(1)} - \frac{\beta_1}{2\beta_0} \Delta P_{n=1}^{(0)} \right] \right\}, \]  

and we obtain for the solution

\[ \Delta q_{n=1}^{\gamma(1)}(t)_{\text{MS}} = \Delta q_{n=1}^{\gamma(1)}(0)_{\text{MS}} \exp \left( M \right), \]  

where

\[ M = \Delta P_{n=1}^{(0)} t + \frac{1}{\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \left[ \Delta P_{n=1}^{(1)} - \frac{\beta_1}{2\beta_0} \Delta P_{n=1}^{(0)} \right] \]

Since

\[ \Delta P_{n=1}^{(0)} = -\frac{1}{4} \Delta \gamma_{\psi}^{0}, \quad \Delta P_{n=1}^{(1)}_{\text{MS}} = -\frac{1}{8} \Delta \gamma_{\psi, \text{MS}}^{(1)} \],

and using the information on the first moments of anomalous dimensions which are listed in Appendices B.1 and B.2, we find that \( M \) turns out to be a triangular matrix in the following form:

\[ M = \begin{pmatrix} a & b & 0 \\ 0 & c & 0 \\ 0 & 0 & d \end{pmatrix} \]

with

\[ a = \frac{1}{\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \left( -\frac{1}{8} \gamma_{\psi, \text{MS}}^{(1), n=1} \right) \]  

35
\[ b = \frac{3}{2} C_F t + \frac{1}{\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \left( -\frac{1}{8} \gamma_{\psi, \overline{\text{MS}}}^{(1), n=1} - \frac{3\beta_1}{4\beta_0} C_F \right) \]  
(C.14)

\[ c = \frac{1}{2} \beta_0 t \]  
(C.15)

\[ d = \frac{1}{\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \left( -\frac{1}{8} \gamma_{\text{NS}, \overline{\text{MS}}}^{(1), n=1} \right) \]  
(C.16)

The matrix \( \exp(M) \) is, therefore, written in the form
\[
\exp(M) = \begin{pmatrix}
e^a & B & 0 \\
0 & e^c & 0 \\
0 & 0 & e^d
\end{pmatrix}
\]  
(C.17)

and thus we obtain from Eqs. (C.7) and (C.9),

\[
\Delta q_\gamma(1, Q^2, P^2)_{\text{MS}} = -\frac{3\alpha}{\pi} N_f < e^2 > \exp \left\{ -\frac{1}{8\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \Delta \gamma_{\psi, \overline{\text{MS}}}^{(1), n=1} \right\} 
\]

\[
\approx -\frac{3\alpha}{\pi} N_f < e^2 > \left\{ 1 - \frac{2}{\beta_0} \left[ \frac{\alpha_s(P^2)}{\pi} - \frac{\alpha_s(Q^2)}{\pi} \right] N_f \right\} 
\]  
(C.18)

\[
\Delta q_{\text{NS}}(1, Q^2, P^2)_{\text{MS}} = -\frac{3\alpha}{\pi} N_f (< e^4 > - < e^2 >) 
\times \exp \left\{ -\frac{1}{8\beta_0} \left[ \frac{\alpha_s(0)}{\pi} - \frac{\alpha_s(t)}{\pi} \right] \Delta \gamma_{\text{NS}, \overline{\text{MS}}}^{(1), n=1} \right\} 
\]

\[
= -\frac{3\alpha}{\pi} N_f (< e^4 > - < e^2 >) 
\]  
(C.19)

where in the last line we use the fact \( \Delta \gamma_{\text{NS}, \overline{\text{MS}}}^{(1), n=1} = 0 \).

Incidentally, under the following approximtion,

\[ b \approx \frac{3}{2} C_F t , \quad a + c \approx c , \]  
(C.20)

\( B \) is evaluated as

\[
B \approx b \left\{ 1 + \frac{1}{2} c + \frac{1}{3!} c^2 + \frac{1}{4!} c^3 + \cdots \right\} = \frac{b}{c} [ e^c - 1 ] 
\]

\[
\approx \frac{3C_F}{\beta_0} \left[ \frac{\alpha_s(P^2)}{\alpha_s(Q^2)} - 1 \right]. 
\]  
(C.21)

This leads to the expression for the first moment of gluon distribution \( \Delta G^\gamma(n = 1, Q^2, P^2)_{\text{MS}} \) given in Eq. (4.6).

[41] We use the same notations as in Ref.[23], except that the symbol $\Delta$ has been appended to all the spin-dependent anomalous dimensions, coefficient functions and photon matrix elements.

Figure Captions

Fig. 1 Deep inelastic scattering on a polarized virtual photon in polarized $e^+e^-$ collision, $e^+e^- \to e^+e^- +$ hadrons (quarks and gluons). The arrows indicate the polarizations of the $e^+$, $e^-$ and virtual photons. The mass squared of the ‘probe’ (‘target’) photon is $-Q^2(-P^2)$ ($\Lambda^2 \ll P^2 \ll Q^2$).

Fig. 2 Factorization scheme dependence of the polarized singlet quark distribution $\Delta q^S_\gamma(x,Q^2,P^2)$ up to NLO in units of $(3N_f\langle e^2\rangle\alpha/\pi)\ln(Q^2/P^2)$ with $N_f=3$, $Q^2=30$ GeV$^2$, $P^2=1$ GeV$^2$, and the QCD scale parameter $\Lambda=0.2$ GeV, for $\overline{\text{MS}}$ (dash-dotted line), CI (solid line), AB (short-dashed line), OS (long-dashed line), AR (dashed line) and DIS$\gamma$ (dash-2dotted line) schemes.

Fig. 3 The polarized singlet quark distribution $\Delta q^S_\gamma(x,Q^2,P^2)$ up to NLO predicted by the OS and DIS$\gamma$ schemes in units of $(3N_f\langle e^2\rangle\alpha/\pi)\ln(Q^2/P^2)$ for $N_f=3$, $Q^2=30$ GeV$^2$, $P^2=1$ GeV$^2$, and $\Lambda=0.2$ GeV, together with the LO result.

Fig. 4 The polarized singlet quark distribution $\Delta q^S_\gamma(x,Q^2,P^2)$ up to NLO in the OS scheme in units of $(3N_f\langle e^2\rangle\alpha/\pi)\ln(Q^2/P^2)$ with three different $Q^2$ values, for $N_f=3$, $P^2=1$ GeV$^2$, and $\Lambda=0.2$ GeV.

Fig. 5 The polarized gluon distribution $\Delta G^\gamma(x,Q^2,P^2)$ beyond the LO in units of $(3N_f\langle e^4\rangle\alpha/\pi)\ln(Q^2/P^2)$ with three different $Q^2$ values, for $N_f=3$, $P^2=1$ GeV$^2$, and $\Lambda=0.2$ GeV.

Fig. 6 Polarized virtual photon structure function $g^\gamma_1(x,Q^2,P^2)$ up to NLO in units of $(3N_f\alpha\langle e^4\rangle/\pi)\ln(Q^2/P^2)$ for $Q^2=30$ GeV$^2$, and $P^2=1$ GeV$^2$ and the QCD scale parameter $\Lambda=0.2$ GeV with $N_f=3$ (solid line). We also plot the LO result (long-dashed line), the Box (tree) diagram (2dash-dotted line) and the Box including non-leading contribution, Box (NL) (short-dashed line).

Fig. 7 Point-like piece of the real photon structure function $g^\gamma_1(x,Q^2)$ in NLO in units of $(3N_f\alpha\langle e^4\rangle/\pi)\ln(Q^2/\Lambda^2)$ for $Q^2=30$ GeV$^2$ with $\Lambda=0.2$ GeV, $N_f=3$ (solid line). Also plotted are the LO result (long-dashed line) and the Box (tree) diagram contribution (short-dashed line).
