Spin-orbit coupling induced enhancement of superconductivity in a two-dimensional repulsive gas of fermions

(Dated: January 20, 2013)

We study a model of a two-dimensional repulsive Fermi gas with Rashba spin-orbit coupling $\alpha_R$, and investigate the superconducting instability using renormalization group approach. We find that in general superconductivity is enhanced as the dimensionless ratio $\frac{1}{2} m \alpha_R^2 / E_F$ increases, resulting in unconventional superconducting states which break time reversal symmetry.

There is a growing interest in materials whose interfaces support a two-dimensional (2D) electron gas and display superconductivity, because of their novel, and potentially technologically useful properties such as electronic transport, magnetism and interplay between structural instabilities\textsuperscript{1,2}. Due to the intrinsic breaking of the inversion symmetry, spin-orbit coupling is expected to play a role in determining the nature of the superconducting state. For example, experimentally the enhancement of transition temperature at LaAlO$_3$/SrTiO$_3$ interfaces\textsuperscript{3} tracks the enhancement of Rashba spin-orbit coupling\textsuperscript{3}. And while the mechanism of superconductivity here is likely related to the electron-phonon mechanism of the bulk materials\textsuperscript{4}, such considerations motivate us to investigate the effect of spin-orbit coupling on the superconducting transition.

For attractive interactions the question has been addressed in Refs\textsuperscript{5,6,7}. In contrast, here we consider a model of repulsive fermions moving in 2D and analyze the nature of the unconventional superconducting state in weak coupling. For a strictly parabolic dispersion in 2D, without spin-orbit coupling, it is known that repulsive interactions do not induce superconductivity to second order in the interaction, unlike in 3D where $p$-wave superconductivity is found at this order. In 2D one has to go to third order\textsuperscript{7} for the Kohn-Luttinger effects to appear. Our motivation is to understand the role of the spin-orbit coupling in this process, to determine whether it can enhance superconductivity, and to study the nature of the superconducting state. Since we treat the Rashba spin-orbit coupling $\alpha_R$ non-perturbatively, we can analyze the relative values of the mean-field transition temperatures $T_c$ for an arbitrary value of the dimensionless ratio $\Theta = \frac{1}{2} m \alpha_R^2 / E_F$, where $m$ is the (bare) fermion mass and $E_F$ is the Fermi energy, measured from the Dirac point (see Fig. 1). In the strictest sense the transition in 2D is of Kosterlitz-Thouless type and at $T_{KT} < T_c$. However, since we are working in the weak coupling limit, the pairing energy scale is much smaller than the zero temperature phase stiffness energy and $1 - T_{KT} / T_c \approx T_c / E_F (1 + \Theta) \ll 1$, justifying the approach presented here.

Due to the spin-orbit interaction, the pair states cannot be chosen to be pure spin singlet or triplet, but appear as linear superposition thereof\textsuperscript{7}. Nevertheless, since the Rashba model\textsuperscript{2}, as well as the short range repulsion\textsuperscript{8}, commute with the $z$-component of the total angular momentum $J_z = L_z + S_z$, we can label the pair states according to $\ell$, the eigenvalue of $J_z$. For small values of $\Theta$ we find that states with high values of relative angular momentum $\ell$ condense first, with $\ell$ decreasing as $\Theta$ increases. For intermediate values of $\Theta$ we find broad regions of stability for $\ell = 4$, with dome-like dependence of $T_c$ on $\Theta$, while in the limit of large $\Theta$, we find $\ell = 2$. In weak coupling we show that all of these states spontaneously break time-reversal symmetry. While we formulate our calculation within more modern renormalization group (RG) approach, our results can be rederived diagrammatically by summing the leading logarithms to all orders in perturbation theory, as has been done traditionally in treating Kohn-Luttinger effect\textsuperscript{9,10,11}. Also, while our approach is similar to that of Ref\textsuperscript{12} (see also\textsuperscript{13,14}), we use a single step RG instead of a two step RG, which we find more economical.

Our starting point is the Hamiltonian for Fermions moving in 2D

$$\mathcal{H} = \mathcal{H}_{\text{kin}} + \mathcal{H}_{\text{int}}$$

(1)

where in momentum representation the kinetic energy (including spin-orbit coupling) is

$$\mathcal{H}_{\text{kin}} = \sum_{\mathbf{k},\alpha} c_{\mathbf{k}\alpha}^\dagger \left( \frac{k^2}{2m} \delta_{\alpha\beta} + \alpha_R (\sigma_{\alpha\beta} \times \mathbf{k}) \cdot \mathbf{n} \right) c_{\mathbf{k}\beta}$$

(2)

and the short-range interaction energy term is

$$\mathcal{H}_{\text{int}} = \frac{u}{2 L^2} \sum_{\mathbf{k}_{1,2,3,4}} \delta_{\mathbf{k}_{1} + \mathbf{k}_{2} + \mathbf{k}_{3} + \mathbf{k}_{4}} c_{\mathbf{k}_{1}\sigma}^\dagger c_{\mathbf{k}_{2}\sigma'}^\dagger c_{\mathbf{k}_{3}\sigma'} c_{\mathbf{k}_{4}\sigma}$$

(3)

As usual, the components of $\mathbf{k}$ belong to the Born-von Karman set $\{2\pi n / L\}$ where $n$ is an integer and $L$ is the linear size of the system. Unlike in Ref\textsuperscript{7}, we consider superconductivity for repulsive interactions, i.e. for $u > 0$, in the weak coupling limit $u_{2D} \ll 1$, where the density of states per spin in 2D for $\alpha_R = 0$ is $\nu_{2D} = \frac{m}{2\pi}$. 

arXiv:1105.2041v2 [cond-mat.supr-con] 4 Nov 2011
The kinetic energy term is diagonalized using the following transformation
\[
\begin{pmatrix}
c_{k\uparrow} \\
c_{k\downarrow}
\end{pmatrix}
= \frac{1}{\sqrt{2}}
\begin{pmatrix}
1 & 1 \text{ie}^{i\phi_k} \\
1 \text{ie}^{-i\phi_k} & -1
\end{pmatrix}
\begin{pmatrix}
a_{k+} \\
a_{k-}
\end{pmatrix},
\]
(4)

Next, we rewrite the Hamiltonian in terms of these helicity eigenmodes. The partition function associated with the path integral over Grassman variables is
\[
S = \int \mathcal{D}[a^\dagger_\lambda(\tau)a_\lambda(\tau)] e^{-S_0 - S_{int}}
\]
(5)

where
\[
S_0 = \int_0^\beta d\tau \sum_{k,\lambda=\pm} a^*_\lambda(\tau) \left( \frac{\partial}{\partial \tau} + \epsilon_{k\lambda} - \mu_F \right) a_\lambda(\tau),
\]
\[
S_{int} = \sum_{1,2,3,4} U(1,2,3,4) a^*_\lambda(1)a^*_\mu(2)a_\mu(3)a_\lambda(4),
\]
(6)

where the single particle energies are (see Fig.1)
\[
\epsilon_{k\lambda} = \frac{k^2}{2m} - \lambda \alpha_R k.
\]
(7)

In the above expressions \(\beta = 1/(k_BT)\), \(\mu_F\) is the exact chemical potential whose value depends on temperature \(T\) and interaction \(u\), in such a way as to preserve average particle density. We adopt a shorthand expression for the multiple summations
\[
\sum_{1,2,3,4,\ldots} \equiv \int_0^\beta d\tau_1 \ldots d\tau_4 \sum_{k_1,\ldots,k_4} \sum_{\mu,\nu,\lambda}(\ldots),
\]
\[
U(1,2,3,4) = -\frac{u}{16L^2} \int_0^\beta d\tau \prod_{j=1}^4 \delta(\tau - \tau_j) \delta_{k_1+k_2+k_3+k_4} \times \left( \mu e^{-i\phi_{k_1}} - \mu e^{-i\phi_{k_2}} \right) \left( \lambda e^{i\phi_{k_3}} - \lambda e^{i\phi_{k_4}} \right),
\]
(8)

and \(a(j) = a_{k_1,\alpha_j}(\tau_j)\) where \(\alpha_j = \{\mu, \nu, \lambda, \rho\}\) and \(\phi_k\) is an azimuthal angle in the momentum plane.

We proceed by integrating out the high energy modes between the energy cutoff \(A\) and \(\Omega \ll A\) about the two Fermi surfaces at \(T = 0\). The expansion is organized by the powers of the dimensionless parameters \(u\nu_D\) and \(\Omega/A\). At first order in the cumulant expansion, we find a correction to the chemical potential \(\mu_F\) from the tadpole diagram shown in Fig.1. This correction is \(\delta \mu_F = -\frac{u}{2} \left( \langle \hat{\rho}_+ \rangle + \langle \hat{\rho}_- \rangle \right)\), where \(\hat{\rho}_\pm = \int \frac{d^Dk}{(2\pi)^D} a^\dagger_{k\pm}a_{k\pm}\). Such a correction to the chemical potential \(\mu\) is restricted to a small window near the Fermi surfaces defined by indices \(\mu\) and \(\lambda\) within the energy \(\Omega\) above and below \(\mu_F\). We write
\[
V_{\mu\lambda}(k, k') = V_{\mu\lambda}^{pp}(k, k') + V_{\mu\lambda}^{ph}(k, k'),
\]
(9)

where the two qualitatively different contributions, arising from the two 2\(^{nd}\) order diagrams shown in Fig.2 are
\[
V_{\mu\lambda}^{pp}(k, k') = -8\mu\lambda(N_+ + N_-)e^{-i\phi_k}e^{i\phi_{k'}} \ln \frac{\Omega}{A},
\]
\[
V_{\mu\lambda}^{ph}(k, k') = \Pi_{\mu\lambda}(k, k') - \Pi_{\mu\lambda}(-k, k'),
\]
(10)

(11)

The density of states on the two Fermi surfaces are
\[
N_{\pm} = \nu_{2D} \left( 1 \pm \sqrt{\frac{\Omega}{\Omega + \Delta}} \right).
\]

In the second "particle-hole"
as the combination $\Lambda$.

Inspecting the form of the remaining terms in (10) as well as the combination $\Lambda^{(S)}(\cos\phi, \cos\phi')$ is real. Note that under time reversal the helicity basis creation and annihilation operators transform as $\tilde{K}_0k = \mp i e^{-i\phi_k} a_k - k$ and $\tilde{K}_0'k = \mp i e^{-i\phi_k} a_k + k$ respectively, where we used $\phi_k = \phi_k + \pi$. The above relation means that the Cooper channel potential $V_{\mu\lambda}(k, k')$ pairs time reversed states, as it should. Inspecting the form of the remaining terms in (10) as well as the combination $\Lambda^{(S)}(\cos\phi, \cos\phi') = \frac{1}{2} \Lambda_{\mu\lambda}(\cos\phi) + \frac{1}{2} \Lambda_{\mu\lambda}(\cos\phi')$ appearing in (11), shows that they are invariant under operations of the 2D rotation group. Additionally, since the remaining terms in the scattering amplitude are even under $k \rightarrow -k$, and independently under $k' \rightarrow -k'$, they can be decomposed into sum over even angular momentum channels

$$V^{(\ell)}_{\mu\lambda}(k, k') = 2m e^{-i\phi_k e^{i\phi_k'}} \Lambda_{\mu\lambda}(\Omega, \cos(\phi_k - \phi_k'))$$

where the dimensionless Fourier coefficients $V^{(\ell)}_{\mu\lambda}$ are functions of $\Theta$ and represent intra- and inter-band pairing amplitudes. In order to determine $V^{(\ell)}_{\mu\lambda}$ we need to evaluate $\Lambda_{\mu\lambda}(\cos\phi)$ in Eq. (13) from Eq. (12). We shift $p \rightarrow p - \frac{1}{2} Q$, where $Q = k - k'$, and transform from the polar coordinates to elliptical coordinates $x \in [1, \infty)$, $\psi \in [0, 2\pi)$ by substituting $p_\parallel = \frac{1}{2} (Q x \cos \psi)$ and $p_\perp = \frac{1}{2} |Q| \sqrt{x^2 - 1} \sin \psi$. In the resulting expression $\psi$ appears only in $\cos \psi$, so we can substitute $y = \cos \psi$. For $\alpha = \beta$ we then perform the integral over $y$ first, which can be done in terms of elementary functions. Similarly, for $\alpha = -\beta$ we perform the integral over $x$ first. Our analysis is based on numerical integration of the remaining integral, which can be done quite fast to any desired accuracy. The final result for the antisymmetrized combination $\Lambda^{(S)}_{\mu\lambda}(\cos\phi)$ is shown in the Fig. 3.

Next, we consider 3rd and 4th order terms in $u$ which renormalize the Cooper channel. These terms can be represented by diagrams shown in Fig. 2 and used to derive the RG equations governing the flows of Cooper channel couplings, which decouple in the angular momentum basis. For $\ell \neq 0$ we find that the renormalized coupling

$$V^{(\ell)}_{\mu\lambda}(k, k') = \frac{u^2 m^{2\ell}}{2\pi} V^{(\ell)}_{\mu\lambda} - \frac{u^4 m^2}{2^\ell} \sum_{\alpha = \pm} N_{\alpha} V^{(\ell)}_{\mu\alpha} V^{(\ell)}_{\mu\alpha} \ln \frac{\Lambda}{\Omega} + \ldots (15)$$

where $\ldots$ represents term of order $u^4$ which do not contain (large) logarithm as well as terms of higher order in $u$. If we define a dimensionless coupling matrix $g^{(\ell)}_{\mu\lambda} = \frac{1}{\Lambda_{\mu\lambda}} u^2 m \sqrt{N_{\mu} N_{\lambda}} V^{(\ell)}_{\mu\lambda}$ and take the logarithmic derivative of the right hand side in (15), then to, and including, $O(u^4)$, we find

$$\frac{dg^{(\ell)}_{\mu\lambda}}{d\ln \Omega} = 2 \sum_{\alpha = \pm} g^{(\ell)}_{\mu\alpha} g^{(\ell)}_{\alpha\lambda}. \quad (16)$$

As usual, we have replaced the bare couplings by renormalized couplings to the order we are working. For $\ell \neq 0$, the initial condition for the above (matrix) differential equation is $g^{(\ell)}_{\mu\lambda}|_{\Omega = A} = \frac{1}{\Lambda_{\mu\lambda}} u^2 m \sqrt{N_{\mu} N_{\lambda}} V^{(\ell)}_{\mu\lambda}$. This equation can be readily integrated by transforming into the orthonormalized basis for $g^{(\ell)}_{\mu\lambda}(\Omega)$ with eigenvalues

$$g^{(\ell)}_{\mu\lambda}(\Omega) = \frac{g^{(\ell)}_{\mu\lambda}}{1 + 2 g^{(\ell)}_{\mu\lambda} \ln \frac{A}{\Omega}}. \quad (17)$$
equation (16) holds as well, provided that we modify the dashed line at \( \Theta = 0 \) and with gap nodes. Comparing their condensation energies we find that the time reversal breaking solution is lower by a factor of 1.5 just below \( T_c \) and by \( e/2 \approx 1.36 \) at \( T = 0 \). For values of \( \Theta \gtrsim 0.005 \), the gap on the larger Fermi surface is much larger than the gap on the smaller one due to the smallness of ratio \( V_+ / V_{++} \). For smaller value of \( \Theta \) the two gaps may be comparable.

In summary, we have studied the superconducting instability of a 2D repulsive Fermi gas with Rashba spin-orbit coupling. We find that due to the polarizable fermion background, the repulsion turns into attraction on the large Fermi surface but not on the small one, giving rise to pairing there. Additional Josephson tunneling, \( V_{++}^{(f)} \), induces pairing on the small Fermi surface by (weak) proximity effect. The resulting unconventional superconducting states are found to break time reversal symmetry. While the transition temperature is not strictly monotonic in the dimensionless ratio \( \Theta = \frac{1}{2} \mu_0 c / E_F \), the general trend is that it grows with increasing \( \Theta \). This experimentally falsifiable feature, may provide means for enhancement of superconductivity in a larger class of 2D electron systems.

Acknowledgements: We wish to thank Prof. L. P. Gor’kov for useful discussions. This work is supported in part by NSF CAREER award under Grant No. DMR-0955561.

FIG. 4: The effective coupling appearing in the expression for \( T_c \approx A e^{-1/|g^{(f)}|} \) as a function of \( \Theta = \frac{1}{2} m_0 c^2 / E_F \). The dashed line at 0.0187 is the \( \Theta \to \infty \) asymptote.

where the initial eigenvalues of \( g_{\mu \lambda}^{(f)}|_{\Theta = 0} \), for \( \ell \neq 0 \), are

\[
\begin{align*}
g_{\pm}^{(f)} &= \frac{u^2}{2} \left( \frac{1}{2} (N_+ V_{++}^{(f)} + N_- V_{--}^{(f)}) \right. \\
&\left. \pm \sqrt{\frac{1}{4} (N_+ V_{++}^{(f)} - N_- V_{--}^{(f)})^2 + N_+ N_- V_{\pm}^{(f)} \Omega^{2}} \right) \quad (18)
\end{align*}
\]

If \( g_{\pm}^{(f)} < 0 \) for some \( \ell \) or \( \Theta \), then the associated renormalized coupling (17) diverges at a scale

\[
T_c^{(f)} \sim \Omega^{(f)} = A e^{-1/|g^{(f)}|} \quad (19)
\]

where \( g^{(f)}_{\mu \lambda} = 2 g_{\mu \lambda}^{(f)} \). While the assignment between \( T_c \) and \( \Omega^{(f)} \) cannot reliably determine the prefactor of the exponential term, the relative dependence on \( a_R \) is in the exponential factor, which we can determine. This allows us to compare the dependence of the ratio of (mean-field) transition temperatures on \( a_R \). For \( \ell = 0 \) the equation (10) holds as well, provided that we modify the initial condition by \( g_{\mu \lambda}^{(f)}|_{\Theta = 0} = \frac{u}{2} \mu \lambda \sqrt{\frac{N_+ N_-}{N_{\mu \lambda} + \frac{1}{2} u^2 \sqrt{N_+ N_-} V_{\pm}^{(f)}(\ell = 0)}} \), and use the eigenvalues of this matrix in the Eq.(17).

To within our numerical accuracy, we find that \( V_{--}^{(f)} = \frac{4}{7} \), while \( V_{--}^{(f)} = 0 \), for any \( \Theta \). In addition, for \( \Theta > O(0.01) \) most dominant angle dependence is in \( V_{++} \), while there is only very weak angle dependence in \( V_{+-} < 0 \). To \( O(u) \), \( g_{++}^{(f)} > 0 \), meaning no pairing instability, and \( g_{--}^{(f)} = 0 \). To \( O(u^2) \) we find that \( g_{\pm}^{(f)} > 0 \) for any \( \Theta > 0 \), due to increase in both \( V_{++}^{(f)} \) and \( V_{--}^{(f)} \), latter of which becomes less negative. This means that superconductivity resides predominantly on the large Fermi surface and is determined by some \( V_{++}^{(f)} \) turning negative (meaning we select – in Eq.(15)). In Fig[4] we show the \( \Theta \) dependence of the couplings for the \( g^{(f)} \)-channel which has the highest \( T_c \). At small value of \( \Theta \), \( \ell \) is very high (see inset of Fig[4]). For the intermediate values of \( \Theta \), starting with \( \approx 0.005 \), we find the sequence \( \ell = 6, 4, 6, 2 \), the last value of which continues to \( \Theta \to \infty \).
