Abstract

A subfamily \( \{F_1, F_2, \ldots, F_{|P|}\} \subseteq \mathcal{F} \) of sets is a copy of a poset \( P \) in \( \mathcal{F} \) if there exists a bijection \( \phi : P \rightarrow \{F_1, F_2, \ldots, F_{|P|}\} \) such that whenever \( x \leq_P x' \) holds, then so does \( \phi(x) \subseteq \phi(x') \). For a family \( \mathcal{F} \) of sets, let \( c(P, \mathcal{F}) \) denote the number of copies of \( P \) in \( \mathcal{F} \), and we say that \( \mathcal{F} \) is \( P \)-free if \( c(P, \mathcal{F}) = 0 \) holds. For any two posets \( P, Q \) let us denote by \( \text{La}(n, P, Q) \) the maximum number of copies of \( Q \) over all \( P \)-free families \( \mathcal{F} \subseteq 2^{[n]} \), i.e. \( \max\{c(Q, \mathcal{F}) : \mathcal{F} \subseteq 2^{[n]}, c(P, \mathcal{F}) = 0\} \).

This generalizes the well-studied parameter \( \text{La}(n, P) = \text{La}(n, P, P_1) \) where \( P_1 \) is the one element poset, i.e. \( \text{La}(n, P) \) is the largest possible size of a \( P \)-free family. The quantity \( \text{La}(n, P) \) has been determined (precisely or asymptotically) for many posets \( P \), and in all known cases an asymptotically best construction can be obtained by taking as many middle levels as possible without creating a copy of \( P \).

In this paper we consider the first instances of the problem of determining \( \text{La}(n, P, Q) \). We find its value when \( P \) and \( Q \) are small posets, like chains, forks, the \( N \) poset and diamonds. Already these special cases show that the extremal families are completely different from those in the original \( P \)-free cases: sometimes not middle or consecutive levels maximize \( \text{La}(n, P, Q) \) and sometimes no asymptotically extremal family is the union of levels.

Finally, we determine (up to a polynomial factor) the maximum number of copies of complete multi-level posets in \( k \)-Sperner families. The main tools for this are the

profile polytope method and two extremal set system problems that are of independent interest: we maximize the number of $r$-tuples $A_1, A_2, \ldots, A_r \in \mathcal{A}$ over all antichains $\mathcal{A} \subseteq 2^{[n]}$ such that (i) $\cap_{i=1}^r A_i = \emptyset$, (ii) $\cap_{i=1}^r A_i = \emptyset$ and $\cup_{i=1}^r A_i = [n]$.

1 Introduction

The very first theorem of extremal finite set theory is due to Sperner [22] and states that if $\mathcal{F}$ is a family of subsets of $[n] = \{1, 2, \ldots, n\}$ such that no two sets in $\mathcal{F}$ are in inclusion, then $|\mathcal{F}| \leq \left(\begin{array}{c} n \\ \lceil n/2 \rceil \end{array}\right)$ holds, and equality is achieved if and only if $\mathcal{F}$ consists of all the $\lceil n/2 \rceil$-element or all the $\lfloor n/2 \rfloor$-element subsets of $[n]$. Families consisting of all the $k$-element subsets of $[n]$ are called (full) levels and we introduce the notation $(\begin{array}{c} n \\ k \end{array}) = \{F \subseteq [n] : |F| = k\}$ for them. Sperner’s theorem was generalized by Erdős [3] to the case when $\mathcal{F}$ is not allowed to contain $k + 1$ mutually inclusive sets, i.e. a $(k + 1)$-chain. He showed that among such families the ones consisting of $k$ middle levels are the largest. In the early eighties, Katona and Tarján [18] introduced a generalization of the problem and started to consider determining the size of the largest family of subsets of $[n]$ that does not contain a configuration defined by inclusions. Such problems are known as forbidden subposet problems and are widely studied (see the recent survey [12]).

In this paper, we propose even further generalizations: we are interested in the maximum number of copies of a given configuration $Q$ in families that do not contain a forbidden subposet $P$. Before giving the precise definitions, let us mention that similar problems were studied by Alon and Shikhelman [1] in the context of graphs when they considered the problem of finding the most number of copies of a graph $T$ that an $H$-free graph can contain.

Definition. Let $P$ be an arbitrary poset and $\mathcal{F}$ a family of sets. We say that $\mathcal{G} \subseteq \mathcal{F}$ is a copy of $P$ in $\mathcal{F}$ if there exists a bijection $\phi : P \rightarrow \mathcal{G}$ such that whenever $x \leq_P x'$ holds, then so does $\phi(x) \subseteq \phi(x')$. Let $\lambda(P, \mathcal{F})$ denote the number of copies of $P$ in $\mathcal{F}$ and for any pair of posets $P, Q$, let us define

$$La(n, P, Q) = \max\{c(Q, \mathcal{F}) : \mathcal{F} \subseteq 2^{[n]}, c(P, \mathcal{F}) = 0\},$$

and for families of posets $\mathcal{P}, \mathcal{Q}$ let us define

$$La(n, \mathcal{P}, \mathcal{Q}) = \max \left\{ \sum_{Q \in \mathcal{Q}} c(Q, \mathcal{F}) : \mathcal{F} \subseteq 2^{[n]}, \forall P \in \mathcal{P} \ c(P, \mathcal{F}) = 0 \right\}.$$

We denote by $P_k$ the chain of length $k$, i.e. the completely ordered poset on $k$ elements. In particular, $P_1$ is the poset with one element. Let us state Erdős’s above mentioned result with our notation.
Theorem 1.1 (Sperner [22] for \( k = 1 \), Erdős [5] for general \( k \)). For every positive integer \( k \) the following holds:

\[
La(n, P_{k+1}, P_1) = \sum_{i=1}^{k} \left( \left\lfloor \frac{n-k}{2} \right\rfloor + i \right).
\]

The area of forbidden subposet problems deals with determining \( La(n, P) = La(n, P, P_1) \) the maximum size of a \( P \)-free family. There are not many results in the literature where other posets are counted. Katona [16] determined the maximum number of 2-chains (copies of \( P_2 \)) in a 2-Sperner (\( P_3 \)-free) family \( F \subseteq 2^n \). This was reproved in [21] and generalized by Gerbner and Patkós in [11].

Theorem 1.2 ([11]). For any \( l > k \) the quantity \( La(n, P_l, P_k) \) is attained for some family \( F \) that is the union of \( l-1 \) levels. Moreover, \( La(n, P_{k+1}, P_k) = \binom{n}{i_1} \cdot \binom{i_1}{i_2-1} \cdot \cdots \cdot \binom{i_k}{n-i_k} \), where \( i_1 < i_2 < \cdots < i_k < n \) are chosen arbitrarily such that the values \( i_1, i_2-i_1, i_3-i_2, \ldots, i_k-i_{k-1}, n-i_k \) differ by at most one.

In this paper, we address the first non-chain instances of the general problem. We will consider the following posets (see Figure 1): let \( \lor_r \) denote the poset on \( r+1 \) elements \( 0, a_1, a_2, \ldots, a_r \) with \( 0 \leq a_i \) for all \( i = 1, 2, \ldots, r \) and we write \( \lor \) for \( \lor_2 \). Similarly, let \( \land_r \) denote the poset on \( r+1 \) elements \( a_1, a_2, \ldots, a_r, 1 \) with \( a_i \leq 1 \) for all \( i = 1, 2, \ldots, r \) and we write \( \land \) for \( \land_2 \). The poset \( N \) contains four elements \( a, b, c, d \) with \( a \leq c \) and \( b \leq c, d \). The butterfly poset \( B \) consists of four elements \( a, b, c, d \) with \( a, b \leq c, d \). Let the generalized diamond poset \( D_k \) be the poset on \( k+2 \) elements \( a, b_1, b_2, \ldots, b_k, c \) with \( a < b_1, b_2, \ldots, b_k < c \).

![Figure 1: The Hasse diagrams of the posets N, B, \( \lor_r \) and \( \land_r \)](image.png)

A family that does not contain \( P_2 \) is called an antichain. A family \( F \) that does not contain \( P_k \) can be easily partitioned into \( k-1 \) antichains \( F_1, \ldots, F_{k-1} \) the following way: let \( F_i \) be the set of minimal elements of \( F \setminus \cup_{j=1}^{i-1} F_j \). We call this the canonical partition of \( F \).

Our first theorem relies on some easy observations.
Theorem 1.3. (a) $La(n, V, P_2) = La(n, \bigwedge, P_2) = \binom{n}{\lfloor n/2 \rfloor}$.

(b) $La(n, \{V, \bigwedge\}, P_2) = \binom{n-1}{\lfloor (n-1)/2 \rfloor}$.

(c) $La(n, B, D_r) = \binom{n}{\lfloor n/2 \rfloor}$.

(d) $La(n, V, \bigwedge, r) = La(n, \bigwedge, \bigvee, r) = \binom{n}{\lfloor n/2 \rfloor}$.

The proof of our next theorem uses the notion of profile vectors (ordinary and $l$-chain profile vectors). Here and throughout the paper $h(x)$ denotes the binary entropy function, i.e. $h(x) = -x \log_2 x - (1 - x) \log_2 (1 - x)$.

Theorem 1.4. (a) $La(n, P_3, \bigwedge, r) = La(n, P_3, V, r) = \binom{n}{i_r} \left( \binom{i_r}{\lfloor i_r/2 \rfloor} \right)$ for some $i_r$ with $i_r = (1 + o(1)) \frac{2^r}{2^r - 1} n$.

(b) $La(n, P_4, D_r) = \binom{n}{j_r} \left( \frac{j_r}{j_r - 1} \binom{r}{\lfloor r/2 \rfloor} \right)$ for some $i_r = (1 + o(1)) \frac{n}{2^r - 1}$ and either $j_r = n - i_r$ or $j_r = n + i_r - 1$.

(c) $2^{(c + o(1))n} \leq La(n, P_3, N) \leq o(2^{3n})$, where $c = h(c_0) + 3c_0h(c_0/(1 - c_0)) = 2.9502...$ with $c_0$ being the real root of the equation $0 = 7x^3 - 10x^2 + 5x - 1$.

Let us return for a moment to the original forbidden subposet problems. The main conjecture of the area was first published by Griggs and Lu in [13].

Conjecture 1.5. For a poset $P$ let us denote by $e(P)$ the largest integer $m$ such that for any $n$, any family $F \subseteq 2^{[n]}$ consisting of $m$ consecutive levels is $P$-free. Then

$$\lim_{n \to \infty} \frac{La(n, P, P_1)}{\binom{n}{\lfloor n/2 \rfloor}} = e(P)$$

holds.

In words, Conjecture 1.5 states that to obtain an asymptotically largest $P$-free family $F \subseteq 2^{[n]}$ one has to consider as many middle levels of $2^{[n]}$ as possible without creating a copy of $P$. Again, we refer the interested Reader to the recent survey [12] to see for which families of posets Conjecture 1.5 has been verified.

However, already Theorem 1.2 shows that to make Conjecture 1.5 valid in the more general context one has to remove at least the word consecutive. All parts of both Theorem 1.3 and Theorem 1.4 suggest that a general conjecture stating that for any pair $P, Q$ of posets $La(n, P, Q)$ is asymptotically attained at a sequence of families consisting of full levels of $2^{[n]}$. But this is not the case at all! There are pairs of posets for which all families consisting of full levels are very far from being optimal. Let us consider $La(n, D_2, P_3)$ the maximum number of 3-chains in diamond-free families. Every family that contains at least three full levels of $2^{[n]}$ contains a copy of $D_2$, while a family that is the union of at most two levels,
For any pair \( \mathcal{F} \) holds.

**Theorem 1.6.** For the generalized diamond posets and integers \( k > l \) the following holds:

\[
\left( \frac{k - 1}{l} \right) \text{La}(n - k + 1, P_3, P_2) \leq \text{La}(n, D_k, D_l) \leq \left( \left( \frac{k + 1}{2} \right) - k \right) \left( \frac{k - 1}{l} \right) \text{La}(n, P_3, P_2).
\]

Note that Theorem 1.6 implies \( \text{La}(n, D_k, D_l) = \theta_{k,l}(\text{La}(n, P_3, P_2)) \) for any fixed \( k \) and \( l \) and the exact value of \( \text{La}(n, P_3, P_2) \) is given by Theorem 1.2. So it is a natural question whether the limit \( d_{k,l} = \lim_{n \to \infty} \frac{\text{La}(n, D_k, D_l)}{\text{La}(n, P_3, P_2)} \) exists and if so, what its value is. In the simplest case \( k = 2, l = 1 \) the above inequalities and Theorem 1.2 imply \( 1/3 \leq d_{2,1} \leq 1 \).

So what can be saved from Conjecture 1.5 in the more general context? Let \( l(P) \) be the height of a poset \( P \), i.e. the length of the longest chain in \( P \). Clearly, if \( \mathcal{F} \) is the union of any \( l(P) - 1 \) full levels, it must be \( P \)-free. On the other hand if \( \mathcal{F}_n = \bigcup_{j=1}^{l(Q)} [n] \) is the union of \( l(Q) \) full levels with \( i_{j+1} - i_j \geq cn \) for some constant \( c \) for all \( j = 1, 2, \ldots l(Q) - 1 \), then \( \mathcal{F}_n \) contains many copies of \( Q \). Therefore we propose the following.

**Conjecture 1.7.** For any pair \( P, Q \) of posets with \( l(P) > l(Q) \) there exist a sequence of \( P \)-free families \( \mathcal{F}_n \subseteq 2^{[n]} \) all of which are unions of full levels such that

\[
\text{La}(n, P, Q) = (1 + o(1))c(Q, \mathcal{F}_n)
\]

holds.

As we have already seen, this conjecture often holds even if \( l(P) \leq l(Q) \). We say that for a pair \( P, Q \) of posets Conjecture 1.7 strongly holds if for large enough \( n \) we have \( \text{La}(n, P, Q) = c(Q, \mathcal{F}_n) \) and almost holds if \( \text{La}(n, P, Q) = O(n^k c(Q, \mathcal{F}_n)) \) for some \( k \) that depends only on \( P \) and \( Q \). In both cases we also assume the family \( \mathcal{F}_n \) is \( P \)-free and is the union of full levels, but we do not assume anything about \( l(P) \) and \( l(Q) \). Parts (a), (c), and (d) of Theorem 1.3 show that Conjecture 1.7 strongly holds for those pairs of posets.

In Theorem 1.3 and Theorem 1.4 we dealt with \( \text{La}(n, P_{l(Q)+1}, Q) \) for different posets \( Q \). (In the case of \( \text{La}(n, B, D_r) \) it is implicit, as the \( B \)-free property implies \( P_d \)-free property.) We knew the place of every element of every copy of \( Q \) in the canonical partition. In the following we deal with these kind of problems. We introduce the following binary operations of posets: for any pair \( Q_1, Q_2 \) of posets we define \( Q_1 \otimes_r Q_2 \) by adding an antichain of size \( r \) between \( Q_1 \) and \( Q_2 \). More precisely, let us assume \( Q_1 \) consists of \( q_1^1, \ldots, q_a^1 \) and \( Q_2 \) consists of \( q_1^2, \ldots, q_b^2 \). Then \( R = Q_1 \otimes_r Q_2 \) consists of \( q_1^1, \ldots, q_a^1, m_1, m_2, \ldots, m_r, q_1^2, \ldots, q_b^2 \). We have \( q_i^1 <_R q_j^1 \) if and only if \( q_i^1 < q_1^1 \) and similarly \( q_i^2 < R q_j^2 \) if and only if \( q_i^2 < q_1^2 \). Also we have \( q_i^1 <_R m_k <_R q_j^2 \) for every \( i, k, j \). Finally, the \( m_k \)'s form an antichain. Note that
l(Q_1 \otimes_r Q_2) = l(Q_1) + l(Q_2) + 1. Let Q \oplus r denote the poset Q \otimes_r \varnothing, where \varnothing is the empty poset, i.e. Q \oplus r is obtained from Q by adding r elements that form an antichain and that are all larger than all elements of Q. Similar operations of posets were considered first in the area of forbidden subposet problems by Burcsi and Nagy [3].

We will obtain bounds on \( La(n, P_{l(Q_1 \otimes_r Q_2)+1}, Q_1 \otimes_r Q_2) \) involving bounds on \( La(n, P_{l(Q_1)+1}, Q_1) \) and \( La(n, P_{l(Q_2)+1}, Q_2) \). For this we will need the following auxiliary statement that can be of independent interest.

**Theorem 1.8.** (a) For every \( r \geq 3 \) and antichain \( A \subseteq 2^n \) the number \( \gamma_{0,n}^r(A) \) of \( r \)-tuples \( A_1, A_2, \ldots, A_r \) with \( \bigcap_{i=1}^r A_i = \varnothing \) and \( \bigcup_{i=1}^r A_i = [n] \) is at most \( n^{2r} \gamma_{0,n}^r(\binom{[n]}{[n/2]}) \). If \( r = 2 \) and \( n \) is even, then \( \gamma_{0,n}^2(A) \leq 2 \gamma_{0,n}^2(\binom{[n]}{[n/2]}) \), while if \( r = 2 \) and \( n \) is odd, then \( \gamma_{0,n}^2(A) \leq \left( \frac{n-1}{[n/2]} \right) \).

(b) For every \( r \) there exists a sequence \( l_n \) such that if \( A \subseteq 2^n \) is an antichain, then the number \( \beta_0^r(A) \) of \( r \)-tuples \( A_1, A_2, \ldots, A_r \) with \( \bigcap_{i=1}^r A_i = \varnothing \) is at most \( n^{2r+1} \beta_0^r(\binom{[n]}{[n/3]}) \).

(c) If \( A \subseteq 2^n \) is an antichain, then \( \beta_0^3(A) \leq \frac{1}{2} n^{2n/3} \binom{2n/3}{[n/3]} \) and this is sharp as shown by \( \left[ \frac{n}{[n/3]} \right] \) if \( n \equiv 0 \pmod{3} \) and by \( \left[ \frac{n}{[n/3]} \right] \) if \( n \equiv 2 \pmod{3} \).

The reason for the strange indices is that we will prove a somewhat more general result in Section 4. The \( r = 2 \) part of Theorem 1.8(a) was proved by Bollobás [2].

**Theorem 1.9.** Let \( Q_1, Q_2 \) be two non-empty posets.

(a) If \( r \geq 2 \), then we have

\[
La(n, P_{l(Q_1)+1}, Q_1 \otimes_r Q_2) \leq n^{2r+2} \max_{0 \leq i < j \leq n} \left\{ \left( \binom{n}{j} \right) \left( \binom{[j-i]}{i} \right) \gamma_{0,j-i}^r \left( \binom{[j-i]/2}{i} \right) \cdot \left( \binom{[n-j]}{[n-j]/2} \right) \cdot \left( \binom{[n-j]}{[n-j]/2} \right) \right\}.
\]

Furthermore, if \( r \geq 3 \) and Conjecture 1.7 almost holds for the pairs \( P_{l(Q_1)+1}, Q_1 \) and \( P_{l(Q_2)+1}, Q_2 \), then so it does for the pair \( P_{l(Q_1 \otimes_r Q_2)+1}, Q_1 \otimes_r Q_2 \).

(b) If \( r = 1 \), then we have

\[
La(n, P_{l(Q_1)+1}, Q_1 \otimes_r Q_2) \leq \max_{0 \leq j \leq n} \left( \binom{n}{j} \right) \cdot \left( \binom{[n-j]}{[n-j]/2} \right) \cdot \left( \binom{[n-j]}{[n-j]/2} \right) \cdot \left( \binom{[n-j]}{[n-j]/2} \right).
\]

Furthermore, if Conjecture 1.7 strongly/almost holds for the pairs \( P_{l(Q_1)+1}, Q_1 \) and \( P_{l(Q_2)+1}, Q_2 \), then so it does for the pair \( P_{l(Q_1 \otimes_r Q_2)+1}, Q_1 \otimes_r Q_2 \).

**Theorem 1.10.** Let \( Q \) be a non-empty poset.

(a) If \( r \geq 2 \) and \( n \in \mathbb{N} \), then there exists an \( i = i(r,n) \) such that

\[
La(n, P_{l(Q)+2}, Q \oplus r) \leq \max_{0 \leq j \leq n} \left( \binom{n}{i} \right) \beta_0^r \left( \binom{[n-i]}{j-i} \right) \cdot \left( \binom{[n-i]}{j-i} \right) \cdot \left( \binom{[n-i]}{j-i} \right) \cdot \left( \binom{[n-i]}{j-i} \right).
\]
Furthermore, if Conjecture 1.7 almost holds for the pair $P_{l(Q)+1}, Q$, then so it does for the pair $P_{l(Q)+2}, Q_1 \oplus r$.

(b) If $r = 1$, then we have

$$La(n, P_{l(Q)+2}, Q \oplus 1) \leq \max_{0 \leq j \leq n} \left\{ \binom{n}{j} La(j, P_{l(Q)+1}, Q) \right\}$$

Furthermore, if Conjecture 1.7 strongly/almost holds for the pair $P_{l(Q)+1}, Q$, then so it does for the pair $P_{l(Q)+2}, Q \oplus 1$.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure2.png}
\caption{The Hasse diagrams of multi-level posets.}
\end{figure}

We can apply Theorem 1.9 and Theorem 1.10 to complete multi-level posets. Let $K_{r_1, r_2, \ldots, r_s}$ denote the poset on $\sum_{i=1}^s r_i$ elements $a_1^1, a_2^1, \ldots, a_1^s, a_1^{r_2}, \ldots, a_2^s, \ldots, a_s^1, a_s^{1}, \ldots, a_s^{r_s}$ with $a_i^k < a_j^l$ if and only if $i < j$. Observe that $\bigvee_r K_{1,r} = K_{2,2}$ and $D_r = K_{1,r,1}.$

Corollary 1.11. For any complete multi-level poset $K_{r_1, r_2, \ldots, r_s}$ Conjecture 1.7 almost holds for the pair $P_{s+1}, K_{r_1, r_2, \ldots, r_s}$.

Corollary 1.12. Conjecture 1.7 strongly holds for the pair $P_{s+1}, K_{r_1, r_2, \ldots, r_s}$ if for every $i < s$ at least one of $r_i$ and $r_i + 1$ is equal to 1.

Corollary 1.12 does not tell us anything about the set sizes in the family containing the most number of copies of $K_{r_1, r_2, \ldots, r_s}$. The next theorem gives more insight for an even more special case.

Theorem 1.13. The value of $La(n, P_{l+3}, K_{r_1,1,\ldots,1,s})$ is attained for a family $F = \bigcup_{j=1}^{l+2} \left( \left[ \frac{n}{j} \right] \right)$, where $i_1 = \lfloor i_2/2 \rfloor$, $i_{l+2} = \lfloor (n + i_{l+1})/2 \rfloor$ and $i_3 - i_2$, $i_4 - i_3$, $\ldots$, $i_{l+1} - i_l$ differ by at most 1.

The rest of the paper is organized as follows: we prove Theorem 1.6 and Theorem 1.3 in Section 2. We explain the profile polytope method and prove Theorem 1.4 in Section 3. Theorem 1.8, Theorem 1.9, Theorem 1.10 and their corollaries are proved in Section 4, while Section 5 contains some concluding remarks.
2 Proofs of Theorem 1.6 and Theorem 1.3

Proof of Theorem 1.6 We start by proving the upper bound. Let \( \mathcal{F} \subseteq 2^{[n]} \) be a \( D_k \)-free family. As for any poset \( P \) the canonical partition of a \( P \)-free family can consist of at most \(|P| - 1\) subfamilies, we can assume that the canonical partition of \( \mathcal{F} \) is \( \bigcup_{i=1}^{k+1} \mathcal{F}_i \). In any copy of \( D_i \) in \( \mathcal{F} \), the sets corresponding to the top and bottom element of \( D_i \) come from \( \mathcal{F}_i \) and \( \mathcal{F}_j \) with \( i - j \geq 2 \). The number of such pairs of indices is \( (k+1) - k \). Let us bound the number of copies of \( D_i \) with top element from \( \mathcal{F}_i \) and bottom element from \( \mathcal{F}_j \). As \( \mathcal{F}_i \cup \mathcal{F}_j \) is \( P_3 \)-free, there are at most \( La(n, P_3, P_2) \) many ways to choose the top and the bottom elements \( F_B \subset F_T \). As \( \mathcal{F} \) is \( D_k \)-free there can be at most \( k - 1 \) sets in \( \mathcal{F} \) lying between \( F_B \) and \( F_T \), so the number of copies of \( D_i \) with \( F_B, F_T \) being top and bottom is at most \( (k-1)^2 \).

The upper bound on \( La(n, D_k, D_l) \) follows.

For the lower bound we need a construction. Let \( \mathcal{F}_1 \cup \mathcal{F}_2 \subseteq 2^{[n-k+1]} \) be the canonical partition of the \( P_3 \)-free family \( \mathcal{F} \) with \( c(P_2, \mathcal{F}) = La(n-k+1, P_3, P_2) \). For \( j = 3, 4, \ldots, k+1 \) let \( \mathcal{F}_j = \{ F \cup [n-k, n-k+j-1] : F \in \mathcal{F}_2 \} \). We claim that \( \mathcal{G} = \bigcup_{i=1}^{k+1} \mathcal{F}_i \) is \( D_k \)-free with \( c(D_1, \mathcal{F}) \geq (k-1) La(n-k+1, P_3, P_2) \). Indeed, every set \( G \in \mathcal{G} \) is contained in a set \( F_{k+1} \in \mathcal{F}_{k+1} \) and contains a set \( F_1 \in \mathcal{F}_1 \), therefore if there was a copy of \( D_k \), we could assume that its bottom element is from \( \mathcal{F}_1 \) and its top element is from \( \mathcal{F}_{k+1} \). But any \( F_{k+1} \in \mathcal{F}_{k+1} \) contains exactly one element from each \( \mathcal{F}_i \) where \( i = 2, 3, \ldots, k \), so there is no space for a copy of \( D_k \). On the other hand, for every pair \( F_1 \subseteq F_2 \) in \( \mathcal{F}_1 \cup \mathcal{F}_2 \) we can add \( l \) sets from \( \{ F_2 \cup [n-k, n-k+j-1] : j = 3, 4, \ldots, k+1 \} \) to form a copy of \( D_i \). For each such pair we will obtain \( (k-1)^2 \) such copies.

Proof of Theorem 1.3 To prove (a), by symmetry, it is enough to show \( La(n, \bigvee, P_2) = \binom{n}{\lfloor n/2 \rfloor} \). Consider any \( \bigvee \)-free family \( \mathcal{F} \subseteq 2^{[n]} \) and its canonical partition \( \mathcal{F}_1 \cup \mathcal{F}_2 \). By the \( \bigvee \)-free property of \( \mathcal{F} \), elements of \( \mathcal{F}_2 \) are contained in at most one copy of \( P_2 \). Also, as the \( \bigvee \)-free property implies the \( P_3 \)-free property, every copy of \( P_2 \) in \( \mathcal{F} \) must contain a set from \( \mathcal{F}_1 \). By Sperner’s theorem \( c(P_2, \mathcal{F}) \leq |\mathcal{F}_2| \leq \binom{n}{\lfloor n/2 \rfloor} \). On the other hand \( \mathcal{F} := \{ F \subseteq [n] : |F| = \lfloor n/2 \rfloor \} \cup \{ [n] \} \) is \( \bigvee \)-free and every \( \lfloor n/2 \rfloor \)-element set forms a copy of \( P_2 \) with \([n]\).

We continue with proving (b). We will need the following definition. For any family \( \mathcal{F} \), the comparability graph of \( \mathcal{F} \) has vertex set \( \mathcal{F} \) and two sets \( F, F' \in \mathcal{F} \) are joined by an edge if \( F \subseteq F' \) or \( F' \subseteq F \) holds. The connected components of the comparability graph of \( \mathcal{F} \) are said to be the components of \( \mathcal{F} \). If a family \( \mathcal{F} \) is both \( \bigvee \)-free and \( \bigwedge \)-free, then its components are either isolated vertices or isolated edges in the comparability graph. Therefore \( c(P_2, \mathcal{F}) \) is the number of components that are isolated edges. It follows that \( La(n, \{ \bigvee, \bigwedge \}, P_2) \leq \frac{1}{2} La(n, \{ \bigvee, \bigwedge \}, P_1) = \binom{n-1}{\lfloor n-1/2 \rfloor} \) where the result in the last equation was proved by Katona and Tarján \[18\]. The construction (given also in \[18\]) \( \mathcal{F} := \binom{[n-1]}{\lfloor (n-1)/2 \rfloor} \cup \{ [n] \} \cup F : F \in \binom{[n-1]}{\lfloor (n-1)/2 \rfloor} \) shows that the above upper bound can be attained.
To prove (c), let us consider a $B$-free family $\mathcal{F} \subseteq 2^{[n]}$ and let $\mathcal{M} = \{M \in \mathcal{F} : \exists F', F'' \in \mathcal{F} \text{ such that } F' \subseteq M \subseteq F''\}$. As $B$-free implies $P_3$-free, we obtain that $\mathcal{M}$ is an antichain, thus $|\mathcal{M}| \leq \binom{n}{\lfloor n/2 \rfloor}$, by Theorem 1.1. Moreover, if $M \in \mathcal{M}$, then there do not exist two elements $F_1, F_2 \in \mathcal{F}$ with $M \subseteq F_1, F_2$. Indeed, by the definition of $\mathcal{M}$ there exists $F' \in \mathcal{F}$ with $F' \subseteq M$, and $F', M, F_1, F_2$ would form a copy of $B$. Similarly, for every $M \in \mathcal{M}$ there exists exactly one element $F \in \mathcal{F}$ with $F \subseteq M$. Therefore a copy of $D_r$ contains $r$ elements of $M$, and they determine the remaining two elements, which implies $c(D_r, \mathcal{F}) \leq \binom{|\mathcal{M}|}{r} \leq \binom{n}{r/2}$). The construction $\mathcal{F} := \emptyset \cup \binom{[n]}{\lfloor n/2 \rfloor}$ shows that this upper bound can be attained.

To prove (d), by symmetry, it is enough to show $La(n, \lor, \land_r) = \binom{n}{\lfloor n/2 \rfloor}$. If $\mathcal{F}$ is $\lor$-free, then it is in particular $P_3$-free. Consider its canonical partition. Then a copy of $\land_r$ contains $r$ elements from $\mathcal{F}_1$ and one from $\mathcal{F}_2$. Moreover, an $r$-tuple from $\mathcal{F}_1$ may form a copy of $\land_r$ with at most one element from $\mathcal{F}_2$, otherwise there is a copy (actually $r$ copies) of $\lor$ in $\mathcal{F}$. As $\mathcal{F}_1$ is an antichain, by Theorem 1.1, the upper bound $La(n, \lor, \land_r) \leq \binom{n}{r/2}$ follows and $\mathcal{F} := \{[n]\} \cup \binom{[n]}{\lfloor n/2 \rfloor}$ shows that this can be attained. \hfill $\square$

3 The profile polytope method

In this section we prove Theorem 1.4 after introducing the notions of profile vectors and profile polytopes. For a family $\mathcal{F} \subseteq 2^{[n]}$ of sets, let $\alpha(\mathcal{F}) = (\alpha_0, \alpha_1, \ldots, \alpha_n)$ denote the profile vector of $\mathcal{F}$, where $\alpha_i = |\{F \in \mathcal{F} : |F| = i\}|$. Many problems in extremal finite set theory ask for the largest size of a family in a class $\mathcal{A} \subseteq 2^{[n]}$. This question is equivalent to determining $\max_{\mathcal{F} \in \mathcal{A}} \alpha(\mathcal{F}) \cdot 1$, where $1$ is the vector of length $n + 1$ with all entries being 1, and $\cdot$ denotes the scalar product.

More generally, consider a weight function $w : \{0, 1, \ldots, n\} \rightarrow \mathbb{R}$, and assume we want to maximize $w(\mathcal{F}) := \sum_{F \in \mathcal{F}} w(|F|)$. Then this is equivalent to maximizing $\alpha(\mathcal{F}) \cdot w$, where $w = (w(0), w(1), \ldots, w(n))$. As $\mathcal{A} \subseteq 2^{[n]}$ holds, we have $\{\alpha(\mathcal{F}) : \mathcal{F} \in \mathcal{A}\} \subseteq \mathbb{R}^{n+1}$ and therefore we can consider its convex hull $\mu(\mathcal{A})$ that we call the profile polytope of $\mathcal{A}$. It is well known that any weight function with the above property is maximized by an extreme point of $\mu(\mathcal{A})$ (a point that is not a convex combination of other points of $\mu(\mathcal{A})$), moreover if such a weight function is non-negative, then it is maximized by an essential extreme point, i.e. an extreme point which is maximal with respect to the coordinate-wise ordering. First results concerning profile polytopes were obtained in [17, 7, 8, 9, 11] and the not too recent monograph of Engel [3] contains a chapter devoted to this topic.

Using this we can determine $La(n, P_3, P_2)$, and using induction with this as the base case one can determine $La(n, P_{k+1}, P_k)$, but in other cases we will need a more powerful tool than ordinary profile vectors. The notion of l-chain profile vector $\alpha_l(\mathcal{F})$ of a family $\mathcal{F} \subseteq 2^{[n]}$ was introduced by Gerbner and Patkós [11] and denotes a vector of length $\binom{n+1}{l}$. 

9
The coordinates are indexed by \(l\)-tuples of \([0,n]\) and \(\alpha_l(\mathcal{F})(i_1,i_2,\ldots,i_l)\) is the number of chains \(F_1 \subset F_2 \subset \cdots \subset F_l\) such that \(F_j \in \mathcal{F}\) and \(|F_j| = i_j\) for all \(1 \leq j \leq l\). For a set \(A \subseteq 2^{[n]}\) one can define the \(l\)-chain profile polytope \(\mu_l(A)\), its extreme points and essential extreme points analogously to the above. Note that for \(l = 1\) we get back the definition of the original profile polytope.

Let \(\mathcal{S}_{n,k}\) be the class of all \(k\)-Sperner families on \([n]\).

**Lemma 3.1** (Gerber, Patkó, [11]). The essential extreme points of \(\mu_l(\mathcal{S}_{n,k})\) are the \(l\)-chain vectors of \(k\)-Sperner families that consist of the union of \(k\) full levels.

Let us state the immediate consequence of the above lemma that we will use in our proofs in the remainder of this section.

**Corollary 3.2.** Let \(l \leq k\) and \(w : \binom{[n]}{l} \to \mathbb{R}^+\) be a weight function such that \(w(\{F_1,F_2,\ldots,F_l\})\) depends only on \(|F_1|,|F_2|,\ldots,|F_l|\). Then the maximum of

\[
\sum_{F_1 \subset F_2 \subset \cdots \subset F_l \in \mathcal{F}} w(\{F_1,F_2,\ldots,F_l\})
\]

over all families \(\mathcal{F} \in \mathcal{S}_{n,k}\) is attained at some family that consists of \(k\) full levels.

**Proof of Theorem 1.4.** To prove (a) we show \(\mathcal{L}(n, P_3, \bigwedge_r) = \binom{n}{i} \left(\left(\binom{r}{i+2}/2\right)\right)\) as the other statement follows by symmetry. Let us consider the canonical partition of a \(P_3\)-free family \(\mathcal{F}\). Note that a copy of \(\bigwedge_r\) contains exactly one element \(F\) from \(\mathcal{F}_2\) and \(r\) elements \(F_1, F_2, \ldots, F_r \in \mathcal{F}_1\) with \(F_i \subset F\) for all \(1,2,\ldots,r\). Let us consider a set \(F \in \mathcal{F}_2\). The sets of \(\mathcal{F}_i\) contained in \(F\) form an antichain, thus by Theorem 1.1 their number is at most \(\binom{|F|}{\lceil|F|/2\rceil}\). Therefore, the number of copies of \(\bigwedge_r\) that contain \(F\) is at most \(\binom{|F|}{\lceil|F|/2\rceil}\) and we obtain

\[
c(\bigwedge_r, \mathcal{F}) \leq \sum_{F \in \mathcal{F}_2} \left(\frac{|F|}{\lceil|F|/2\rceil}\right) \leq \max_{A \in \mathcal{S}_{n,1}} \sum_{A \in A} \left(\frac{|A|}{\lceil|A|/2\rceil}\right)
\]

Therefore if we set \(w(i) := \binom{i+2}{i}/2\), then we can apply Corollary 3.2 with \(l = k = 1\) to obtain \(c(\bigwedge_r, \mathcal{F}) \leq \max_{0 \leq i \leq n} \binom{n}{i} w(i)\). On the other hand, the families \(\mathcal{F}(i) = \binom{[n]}{i} \cup \binom{[n]}{i+2}/2\) are \(P_3\)-free and \(c(\bigwedge_r, \mathcal{F}(i)) = \binom{n}{i} w(i)\) showing \(\mathcal{L}(n, P_3, \bigwedge_r) = \max_{0 \leq i \leq n} \binom{n}{i} w(i)\). To obtain the value of \(i_r\) we need to maximize \(f(i) := \binom{n}{i} w(i)\). Considering

\[
\frac{f(i)}{f(i+1)} = \frac{i+1}{n-i} \cdot \frac{\prod_{j=0}^{i-1} \binom{i}{j} - j}{\prod_{j=0}^{i-1} \binom{i+1}{j} - j} = (1 + o(1)) \frac{i+1}{2^r(n-i)}
\]
when $i$ tends to infinity with $n$. For constant values of $i$, the ratio $f(i)/f(i + 1)$ is easily seen to be smaller than 1 (if $n$ is big enough), therefore the maximum of $f(i)$ is attained at $i_r = (1 + o(1))\frac{2^r}{2^r+1}n$ as stated.

To prove (b) we consider the canonical partition of a $P_3$-free family $\mathcal{F} \subseteq 2^{[n]}$. Any copy of $D_r$ in $\mathcal{F}$ must contain one set from $\mathcal{F}_1, \mathcal{F}_2$ each and $r$ sets from $\mathcal{F}_3$. For any $F_1 \subseteq \mathcal{F}_1, F_3 \subseteq \mathcal{F}_3$ with $F_1 \subseteq F_3$, the number of copies of $D_r$ containing $F_1$ and $F_3$ is $\binom{m}{r}$, where $m = |\mathcal{M}_{F_1,F_3}|$ with $\mathcal{M}_{F_1,F_3} = \{F \in \mathcal{F}_2 : F_1 \subset F \subset \mathcal{F}_3\}$. As $\mathcal{M}'_{F_1,F_3} = \{M \setminus F_1 : M \in \mathcal{M}_{F_1,F_3}\}$ is on antichain in $\mathcal{F}_3 \setminus F_1$, we have $m \leq \binom{|\mathcal{F}_3| - |F_1|}{r}$, Therefore, we obtain
\[
c(D_r, \mathcal{F}) \leq \sum_{F_1 \in \mathcal{F}_1, F_3 \in \mathcal{F}_3, F_1 \subseteq F_3} \binom{|\mathcal{F}_3| - |F_1|}{r} \leq \max_{0 \leq i < j \leq n} \binom{n}{j-i} \binom{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{2}}{i-r}
\]
where to obtain the last inequality we applied Corollary 3.2 with $l = k = 2$ and $w(i, j) = \binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{i-r}$. Observe that if $i_r$ and $j_r$ are the values for which this maximum is taken, then for the family $\mathcal{F} = \binom{[n]}{i_r} \cup \binom{[n]}{j_r} \cup \binom{[n]}{1+(i_r + j_r)/2}$ we have $c(D_r, \mathcal{F}) = \left(\binom{n}{i_r}\right)\left(1 + \binom{\binom{|F_3| - |F_1|}{2}}{2}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{i_r}}\left(\binom{n}{j_r}\right)\left(\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{2}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{j_r}}$.

To obtain the value of $i_r$ and $j_r$ let us fix $x = j - i$ first. Note that $\binom{n}{i_r}\left(\frac{n}{i_r}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{i_r}} = \binom{n}{j_r}\left(\frac{n}{j_r}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{j_r}}$, so we have
\[
\binom{n}{i_r + x}\left(\frac{n}{i_r + x}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{i_r + x}} = \binom{n}{n - 1 - x}\left(\frac{n}{n - 1 - x}\right)^{\binom{\binom{\binom{|F_3| - |F_1|}{2}}{2}}{n - 1 - x}} = \frac{n - x - i}{i + 1},
\]
which implies that $i_r + j_r = n$ or $i_r + j_r = n - 1$ holds.

Let $g(i) = \binom{n}{i}\left(\frac{n}{i}\right)^{\binom{\binom{|F_3| - |F_1|}{2}}{i}}$, then
\[
g(i+1) - g(i) = (1 + o(1))\frac{(n-2i-1)(n-2i-2)}{(i+1)^{2+2\tau}}.
\]
This implies the maximum of $g(i)$ is attained at $i = (1 + o(1))\frac{2^r-1}{2^r+1}$.

To prove (c) we again consider the canonical partition of a $P_3$-free family $\mathcal{F} \subseteq 2^{[n]}$. A copy of $N$ in $\mathcal{F}$ must contain two sets from $\mathcal{F}_1$ and two from $\mathcal{F}_2$. Let $a, b, c, d$ be the four elements of $N$ with $a \leq c$ and $b \leq c, d$. For every copy of $N$ in $\mathcal{F}$ there is a bijection $\phi$ from $N$ to that copy. Then we count the copies of $N$ in $\mathcal{F}$ according to the images $\phi(b), \phi(c)$. Clearly, they form a 2-chain in $\mathcal{F}$, the possible images of $d$ form an antichain among those sets of $\mathcal{F}_2$ that contain $\phi(b)$ and the possible images of $a$ form an antichain among those sets of $\mathcal{F}_1$ that are contained by $\phi(c)$. Therefore, we obtain
\[
c(N, \mathcal{F}) \leq \sum_{F_1, F_2 \in \mathcal{F}, F_1 \subseteq F_2} \binom{n-|F_1|}{\frac{|F_2|}{2}} \binom{|F_2|}{2} \leq \max_{0 \leq i < j \leq n} \binom{n}{j-i} \binom{n}{j} \binom{n-i}{\frac{j}{2}},
\]
where to obtain the last inequality we applied Corollary 3.2 with $l = k = 2$ and $w(i, j) = \binom{n-i}{\frac{j}{2}} \binom{j}{i}$. We have $\binom{j}{i} = \binom{n-j+i}{\frac{j}{2}}$, thus we get

$$c(N, \mathcal{F}) \leq \max_{0 \leq i < j \leq n} \binom{n}{j-i} \binom{n-j+i}{\frac{j}{2}} \binom{n-i}{\frac{j}{2}} = \max_{0 \leq i < j \leq n} o(2^{n+j+i+n-i+j}) = o(2^{3n}).$$

Note that $j = \lceil 3n/4 \rceil$ and $i = \lfloor n/4 \rfloor$ show the exponent cannot be improved with this method.

To obtain the lower bound consider the $P_3$-free families $\mathcal{F}_{i,j} = \binom{n}{i} \cup \binom{n}{j}$ with $0 \leq i < j \leq n$. Observe that we have $c(N, \mathcal{F}_{i,j}) \geq \frac{1}{4}(\binom{n}{i})^2 \binom{n-i}{j-i} = g(i, j)$ (the 1/4-factor is due to the fact that copies of $B$ are counted 4 times as copies of $N$). To maximize $g(i, j)$ we first fix $j-i$ and consider

$$\frac{g(i+1,j+1)}{g(i,j)} = \frac{(n-j)^2(j+1)^2}{(i+1)^2(j+1)(n-i)}.$$

It is easy to see that this fraction becomes smaller than 1 when $i$ is roughly $n-j+1$. Thus the maximum of $g(i,j)$ is asymptotically achieved when $i = n-j$.

Similarly, we have

$$\frac{g(n-j-1,j+1)}{g(n-j,j)} = \frac{(n-j)(j+1)^3(n-j)^3}{(j+1)(2j-n+2)^3(2j-n+1)^3}.$$

Therefore, if we write $j = (c + o(1))n$, we obtain that $g$ is maximized when $\frac{c^2(1-c)^4}{(12c-1)^3} = 1$. After taking the square root of the expression on the left hand side, this is equivalent to that $0 = 7c^3 - 10c^2 + 5c - 1$ holds. The solution of this equation is $c_0 = 0.69922...$. As $g(n-j,j) = \frac{1}{4}(\binom{n}{j})^3 = \Omega(2^{h(j/n)+3/2h((n-j)/j)/n^2})$, the lower bound follows by plugging in $j = 0.69922n$. \qed

4 The $\otimes_r$ operation and copies of complete multi-level posets

In this section we prove results concerning the binary operation $Q_1 \otimes_r Q_2$. We introduce two types of profile vectors.

For a family $\mathcal{F} \subseteq 2^n$ of sets, let $\beta_r(\mathcal{F}) = (\beta^r_0, \beta^r_1, \ldots, \beta^r_{n-1})$ denote the $r$-intersection profile vector of $\mathcal{F}$, where $\beta^r_i = |\{ \mathcal{F} \subseteq 2^n : |\bigcap F_j| = i \}|$.

For a family $\mathcal{F} \subseteq 2^n$ of sets, let $\gamma^r(\mathcal{F}) = (\gamma^r_0, \gamma^r_1, \ldots, \gamma^r_{n-1})$ denote the $r$-intersection-union profile vector of $\mathcal{F}$, where $\gamma^r_{i,j} = |\{ \mathcal{F} \subseteq 2^n : |\bigcap F_i \cup \cdots \cup F_j| = j \}|$. Note that if $\mathcal{A} \subseteq 2^n$ is
an antichain, then \( \gamma_{i,j}(A) > 0 \) implies \( j - i \geq 2 \), therefore the number of non-zero coordinates in \( \gamma^r(A) \) is at most \( \binom{n+1}{2} - n = \binom{n}{2} \leq n^2 \).

Let us illustrate with two examples why these profile vectors can be useful in counting copies of different posets. Let \( F \) be a \( P_3 \)-free and \( G \) be a \( P_4 \)-free family. We will estimate 
\( c(K_{p,r},F) \) and \( c(K_{p,r,s},G) \). If we consider the canonical partitions of \( F = F_1 \cup F_2 \) and \( G = G_1 \cup G_2 \cup G_3 \), then a copy of \( K_{p,r} \) in \( F \) contains \( p \) sets from \( F_1 \) and \( r \) sets from \( F_2 \). If we fix \( F_1, \ldots, F_r \in F_2 \), then the \( p \) "bottom" sets of the copies of \( K_{p,r} \) in \( F \) containing \( F_1, \ldots, F_r \) form an antichain in \( \{ F \in F_1 : F \subseteq \bigcap_{j=1}^{r} F_j \} \). Therefore, by Theorem 1.1 the number of these copies is at most \( \binom{\left| \bigcap_{j=1}^{r} F_j \right|}{p} \), so summing up for all possible \( r \)-tuples of \( F_2 \) we obtain 
\( c(K_{p,r},F) \leq \beta^r(F) \cdot \mathbf{w}_p \) and consequently

\[
La(n, P_3, K_{p,r}) \leq \max\{ \beta^r(A) \cdot \mathbf{w}_p : A \subseteq 2^{[n]} \text{ is an antichain} \},
\]

where the \( j \)th entry of the vector \( \mathbf{w}_p \) is \( \binom{p}{j} \).

Similarly, if we consider the canonical partition of \( G = G_1 \cup G_2 \cup G_3 \), then a copy of \( K_{p,r,s} \) in \( G \) contains \( p \) sets from \( G_1 \), \( r \) sets from \( G_2 \) and \( s \) sets from \( G_3 \). If we fix \( G_1, \ldots, G_r \in G_2 \), then the bottom \( p \) and top \( s \) sets of copies of \( K_{p,r,s} \) containing \( G_1, \ldots, G_r \) form antichains in \( \{ G \in G_1 : G \subseteq \bigcap_{j=1}^{r} G_j \} \) and \( \{ G \in G_3 : G \supseteq \bigcup_{j=1}^{r} G_j \} \). Therefore, using again Theorem 1.1 we obtain 
\( c(K_{p,r,s},G) \leq \gamma^r(G_2) \cdot \mathbf{w}_{p,s} \) and consequently

\[
La(n, P_4, K_{p,r,s}) \leq \max\{ \gamma^r(A) \cdot \mathbf{w}_{p,s} : A \subseteq 2^{[n]} \text{ is an antichain} \},
\]

where the \((i,j)\)th entry of the vector \( \mathbf{w}_{p,s} \) is \( \binom{p}{i} \binom{n-j}{s} \). Therefore determining the convex hull (and more importantly its extreme points) of the \( r \)-intersection profile vectors and \( r \)-intersection-union profile vectors of antichains would yield upper bounds on \( La \)-functions of complete multi-level posets.

We are not able to determine these convex hulls, we will only obtain upper bounds on the coordinates of these profile vectors. Note that Theorem 1.8 is about special coordinates, so the next two theorems imply that result.

**Theorem 4.1.** (a) If \( F \subseteq 2^{[n]} \) is an antichain and \( j - i \) is even, then 
\[
\gamma_{i,j}^2(F) = \gamma_{i,j}^2((\binom{n}{i} \binom{n-j}{j-i}/2)) = \frac{1}{2} \binom{n}{i} \binom{n-j}{j-i}/2.
\]
If \( j - i \) is odd, then
\[
\gamma_{i,j}^2(F) = \gamma_{i,j}^2((\binom{n}{i} \binom{n-j}{j-i}/2)) = \frac{1}{2} \binom{n}{i} \binom{n-j}{j-i}/2.
\]
(b) If \( F \) is an antichain and \( r \geq 3 \), then 
\[
\gamma_{i,j}^r(F) \leq n^2 \gamma_{i,j}^r((\binom{n}{i} \binom{n-j}{j-i}/2)).
\]

During the proof we will use several times that the number of pairs \( A \subset B \subset [n] \) with \( |A| = a, |B| = b \) is \( \binom{n}{a} \binom{n-a}{b-a} = \binom{n}{b} \binom{n-b}{a} = \binom{n}{b-a} \binom{n-a}{b} \). The first calculation is obvious, for the second pick first \( B \setminus A \) from \([n]\) and then \( A \) from \([n] \setminus (B \setminus A)\).

**Proof.** To see (a), we first consider the special case \( i = 0, j = n \). Observe that \( \gamma_{0,n}^2(F) \) is the number of complement pairs in \( F \). In an antichain, by Theorem 1.1 this is at most
If $n$ is even, then this is achieved when $\mathcal{F} = \binom{[n]}{a/2}$, while the case of odd $n$ was solved by Bollobás [2], who showed that the number of such pairs is at most $\binom{n-1}{[n/2]-1}$ and this is sharp as shown by $\{F \in \binom{[n]}{[n/2]} : 1 \in F\} \cup \{F \in \binom{[n]}{[n/2]} : 1 \notin F\}$.

To see the general statement observe that for pair $I \subset J$ writing $\mathcal{F}_{I,J} = \{F \in \mathcal{F} : I \subset F \subset J\}$ we have $\gamma^r_{i,j}(\mathcal{F}) = \sum_{I \in \binom{[n]}{i}, J \in \binom{[n]}{j}} \gamma^2_{0,j-i}(\mathcal{F}_{I,J})$. Therefore if $j - i$ is even we obtain $\gamma^2_{i,j}(\mathcal{F}) \leq \binom{n}{i} \binom{n}{j} \gamma^2_{0,j-i}(\mathcal{F}_{(j-i)/2}) = \gamma^2_{i,j}(\mathcal{F}_{(j-i)/2})$, while if $j - i$ is odd, we obtain $\gamma^2_{i,j}(\mathcal{F}) \leq \binom{n}{i} \binom{n}{j} \gamma^2_{I,J}(\mathcal{F}_{(j-i)/2}) - 1$.

To show (b) it is enough to prove the statement for $i = 0, j = n$. Indeed, $\gamma^r_{i,j}(\mathcal{F}) = \sum_{I,J} \gamma^r_{0,j-i}(\mathcal{F}_{I,J}) \leq \binom{n}{i} \binom{n}{j} \gamma^r_{0,j-i}(\mathcal{F}_{(j-i)/2}) = \gamma^r_{i,j}(\mathcal{F}_{(j-i)/2})$.

We proceed by induction on $r$. We postpone the proof of the base case $r = 3$, and assume the statement holds for $r - 1$ and any $i < j$. Let us consider $r - 1$ sets $F_1, \ldots, F_{r-1}$ of $\mathcal{F}$ and examine which sets can be added to them as $F_r$ to get empty intersection and $[n]$ as the union. Let $\mathcal{F}'$ be the family of those sets. Let $A = \cap_{i=1}^{r-1} F_i$ and $B = \cup_{i=1}^{r-1} F_i$ with $a = |A|$ and $b = |B|$. Then members of $\mathcal{F}'$ contain the complement of $B$ and do not intersect $A$, and $\mathcal{F}'$ is Sperner. If we remove $B$ from them, the resulting family is Sperner on an underlying set of size $b - a$, thus have cardinality at most $\left\lfloor \frac{n}{(b-a)/2} \right\rfloor$ as required. Note that we count every $r$-tuple $F_1, \ldots, F_r$ exactly $r$ times. It implies

$$r \gamma^r_{0,n}(\mathcal{F}) \leq \sum_{a<b} \gamma^r_{a,b}(\mathcal{F}) w(a,b) = \gamma^{r-1}(\mathcal{F}) \cdot w \leq n^2 \max_{a<b} \gamma^{r-1}_{a,b}(\mathcal{F}) w(a,b).$$

By induction this is at most $n^2 n^{2r-2} \max_{a<b} \gamma^{r-1}_{a,b}(\binom{n}{(a+b)/2}) w(a,b)$. Let

$$\gamma_{a,b} = \binom{n}{a+b}\binom{[n]}{[(a+b)/2]} w(a,b),$$

$$f(a,b) = n \binom{n}{b-a} \binom{n-(b-a)}{a} \gamma_{a,b} = \binom{n}{b-a} \binom{n-(b-a)}{a} \gamma_{a,b}.$$

If we fix $b-a$ and consider $\frac{f(a,b)}{\binom{n}{a+b}} = a + 1 \binom{n}{a+b} - a$, we can see that the maximum is taken when $b+a = n$ or $b+a = n-1$ depending on the parity of $b-a$ and $n$.

Let $a^*, b^*$ be the values for which the above maximum is taken. Note that for any $a^* < p < b^*$ we have $\gamma^r_{0,n}(\binom{n}{p}) \geq (\gamma^r_{b^*})^{\gamma^{r-1}_{b^*-a^+,(p-b^*)} \gamma^{r-1}_{0,b^*-a^+,(p-b^*)}/(p-n-b^*)} \gamma^{r-1}_{0,b^*-a^+,(p-b^*)}/(p-n-b^*)}$, by counting only those $r$-tuples where the first $r-1$ sets have intersection of size $a^*$ and union of size $b^*$. (This way we count those $r$-tuples at most $r$ times. This is exactly $f(a^*, b^*)$ if $p = \lfloor n/2 \rfloor = \lfloor (a^* + b^*)/2 \rfloor$, so we obtained $r \gamma^r_{0,n}(\mathcal{F}) \leq n^2 r \gamma_{0,n}(\binom{n}{[n/2]})$ as required.

For $r = 3$ we similarly consider two members of $\mathcal{F}$ and examine which sets can be added to them to get empty intersection and $[n]$ as the union. This leads to

$$3 \gamma^3_{0,n}(\mathcal{F}) \leq n^2 \max_{a<b} \gamma^2_{a,b}(\mathcal{F}) w(a,b).$$
Note that if the maximum is taken at $a'$ and $b'$ with $b' - a' = 0$, then part (a) of the theorem gives $\gamma_{a',b'}^2(\mathcal{F}) \leq \gamma_{a',b'}^2\left(\binom{\lceil n \rceil}{\lceil b' + a' \rceil/2}\right)$, and $3\gamma_{0,n}^3(\mathcal{F}) \leq n^2\gamma_{a',b'}^2\left(\binom{\lceil n \rceil}{\lceil b' + a' \rceil/2}\right)w(a',b')$. This essentially lets us use $r = 2$ as the base case of induction, and finish the proof of this case similarly to the induction step above.

Let us choose $a^*, b^*$ that maximizes this upper bound with $b^* - a^* = b' - a'$. Similarly to the computation about $f(a,b)$, we have $a^* + b^* = n$ or $n - 1$ depending on the parity of $n$. Then we obtain $3\gamma_{0,n}^3(\mathcal{F}) \leq n^2\gamma_{a^*,b^*}^2\left(\binom{\lceil n \rceil}{\lceil b' + a' \rceil/2}\right)w(a^*,b^*)$. The lower bound on $3\gamma_{0,n}^3\left(\binom{\lceil n \rceil}{\lceil n/2 \rceil}\right)$ is $\gamma_{a^*,b^*}^2\left(\binom{\lceil n \rceil}{\lceil n/2 \rceil}\right)\gamma_{0,n}^2(\mathcal{F})w(a^*,b^*)$ as in the inductive step.

However, if $b' - a'$ is odd, then $\gamma_{a^*,b^*}\left(\binom{\lceil n \rceil}{\lceil n/2 \rceil}\right) = 0$. But we know by part (a)

$$\gamma_{a^*,b^*}^2(\mathcal{F})w(a',b') \leq \left(\frac{b' - a' - 1}{b' - (b' - a')/2 - 1}\right)\left(\frac{n}{b'}\right)w(a',b').$$

Similarly to the previous cases, if $b' - a'$ is fixed, then the maximum of the right hand side is taken for some $a^*, b^*$ with $b^* - a^* = b' - a'$ and $a^* + b^* = n$ if $n$ is odd, and $a^* + b^* = n - 1$ or $a^* + b^* = n + 1$ if $n$ is even. Thus we can assume $\lfloor n/2 \rfloor = (a^* + b^* - 1)/2$. On the other hand, since $b^* - a^*$ is odd, we have

$$3\gamma_{0,n}^3\left(\binom{\lceil n \rceil}{\lceil a^* + b^* - 1 \rceil/2}\right) \leq \left(\frac{n}{b' - 1}\right)\left(\frac{b^* - a^* - 1}{a^*}\right)\frac{1}{2}\left(\frac{(b^* - a^* - 1)/2}{b^* - a^* - 1}\right)\left(\frac{b^* - a^* - 1}{n + b^* - 1}\right),$$

by counting only those triples where two of the sets have intersection of size $a^*$ and union of size $b^* - 1$. We can pick first the $(b^* - 1)$-set $B$ and the $a^*$-set $A$ in $\binom{n}{\lfloor a^* + b^* - 1 \rfloor}$ ways, then among $\{G \in \binom{\lceil n \rceil}{\lceil a^* + b^* - 1 \rfloor/2} : A \subset G \subset B\}$ we can pick a pair $G_1, G_2$ with $G_1 \cap G_2 = A$, $G_1 \cup G_2 = B$ in $\binom{b^* - a^* - 1}{(b^* - a^* - 1)/2}$ ways and then the third set contains the complement of $B$ and does not intersect $A$. Using that $\left(\frac{b^* - a^* - 1}{b^* - a^* - 1}\right) \geq \left(\frac{b^* - a^* - 1}{(b^* - a^* - 1)/2}\right)$ this implies

$$3\gamma_{0,n}^3(\mathcal{F}) \leq 3n^2\gamma_{0,n}^3\left(\binom{\lceil n \rceil}{\lceil a^* + b^* - 1 \rceil/2}\right) \leq 3n^3\gamma_{0,n}^3\left(\binom{\lceil n \rceil}{\lfloor n/2 \rfloor}\right),$$

as $b^* \geq n/2$.

\begin{flushright}
\Box
\end{flushright}

\textbf{Theorem 4.2. (a)} For any antichain $\mathcal{F} \subseteq 2^{[n]}$ we have $\beta_2^2(\mathcal{F}) \leq \beta_2^2(\binom{\lceil n \rceil}{\lfloor n/2 \rfloor})$, where $j(i) = i + [(n - i)/3]$ if $n - i \equiv 0, 1 \mod 3$ and $j(i) = i + [(n - i)/3]$ if $n - i \equiv 2 \mod 3$.

(b) For every $r \geq 3$ and $i \leq n$ there exists $j(r,i,n)$ such that $\beta_r^2(\mathcal{F}) \leq n^{2r+1}\beta_i^2(\binom{\lceil n \rceil}{j(r,i,n)})$ holds for any antichain $\mathcal{F} \subseteq 2^{[n]}$.

\begin{flushleft}
\textbf{Proof.} First we prove (a) for the special case $i = 0$. Let $\mathcal{F} \subseteq 2^{[n]}$ be an antichain, and let $\overline{\mathcal{F}} = \{\overline{F} : F \in \mathcal{F}\}$, where $\overline{F} = [n] \setminus F$. As $\mathcal{F}$ is an antichain, so is $\overline{\mathcal{F}}$, and thus $\mathcal{F} \cup \overline{\mathcal{F}}$ is $P_3$-free. Note that for every pair $F_1, F_2 \in \mathcal{F}$ with $|F_1 \cap F_2| = 0$ and $F_1 \cup F_2 \neq [n]$, we
have two 2-chains $F_1 \not\subseteq F_2$ and $F_2 \not\subseteq F_1$. Also, every 2-chain in $\mathcal{F} \cup \overline{\mathcal{F}}$ comes from a pair $F_1, F_2 \in \mathcal{F}$ with $|F_1 \cap F_2| = 0$ and $F_1 \cup F_2 \neq [n]$.

Therefore, if we take the canonical partition of $\mathcal{F} \cup \overline{\mathcal{F}}$ into $\mathcal{F}_1 \cup \mathcal{F}_2$ and introduce the weight function $w(F) = \frac{1}{2}\binom{|F|}{2}$ if $F \in \mathcal{F}_2, \overline{\mathcal{F}} \not\subseteq \mathcal{F}_2$ and $w(F) = 1/2$ if $F \in \mathcal{F}_2, \mathcal{F} \in \mathcal{F}_2$, then the number of disjoint pairs in $\mathcal{F}$ equals $\sum_{F \in \mathcal{F}_2} w(F)$. This weight function does not depend only on the size of $F$, but $w'(f) = \frac{1}{2}\binom{|F|}{2}$ does and obviously $w(F) \leq w'(F)$ holds for all $F$'s. As proved by Katona in Theorem 3 of [14] this weight function is maximized when $\mathcal{F}_2 = \binom{[n]}{\lceil 2n/3 \rceil}$. As $\mathcal{F}_2$ does not contain complement pairs, it also maximizes $w$.

To see the general statement of (a), we can apply the special case to any $I \subseteq [n]$ and $\mathcal{F}_I = \{F \setminus I : I \subseteq F \subseteq \mathcal{F}\}$. We obtain

$$\beta_i^2(\mathcal{F}) = \sum_{I \in \binom{[n]}{i}} \beta_i^2(\mathcal{F}_I) \leq \binom{n}{i} \beta_i^2 \binom{[n-i]}{j(i) - i} = \beta_i^2 \binom{[n]}{j(i)}.$$  

To see (b), let $\mathcal{F} \subseteq 2^{[n]}$ be antichain. Observe

$$\beta_i^r(\mathcal{F}) = \sum_{j=i+1}^n \gamma_{i,j}^r(\mathcal{F}) \leq \max_{j=i+1}^{n} \gamma_{i,j}^r(\mathcal{F}) \leq n^{r+1} \max_{j=i+1}^n \gamma_{i,j}^r \binom{[n]}{\lceil (i+j)/2 \rceil} \leq n^{2r+1} \beta_i^r \binom{[n]}{j(r,i,n)}$$

where $j(r,i,n) = \lfloor (i+j^*)/2 \rfloor$ with $j^*$ being the value of $j$ that maximizes $\gamma_{i,j}^r \binom{[n]}{\lceil (i+j)/2 \rceil}$. The penultimate inequality follows from Theorem 4.1. \hfill \Box

**Proof of Theorem 1.4** Let $Q_1, Q_2$ be non-empty posets and let us consider the canonical partition of a $P_1(Q_1 \otimes Q_2)+1$-free family $\mathcal{F} \subseteq 2^{[n]}$. Then in any copy of $Q_1 \otimes_r Q_2$ in $\mathcal{F}$, if $F_1, \ldots, F_r$ correspond to the $r$ middle elements forming an antichain, we must have $F_1, \ldots, F_r \in \mathcal{F}_{(Q_1)}$. Also, if a copy of $Q_1 \otimes_r Q_2$ contains $F_1, \ldots, F_r$, then the sets corresponding to the $Q_1$ part of $Q_1 \otimes_r Q_2$ must be contained in $\bigcap_{i=1}^r F_i$, while the sets corresponding to the $Q_2$ part of $Q_1 \otimes_r Q_2$ must contain $\bigcup_{i=1}^r F_i$. Therefore the number of copies of $Q_1 \otimes_r Q_2$ in $\mathcal{F}$ that contain $F_1, \ldots, F_r$ is at most $La(\lceil \bigcap_{i=1}^r F_i \rceil, P_{(Q_1)}(Q_1) \cdot La(n - \bigcup_{i=1}^r F_i, P_{(Q_2)}(Q_2) \cdot Q_2))$. We obtained that the total number of copies of $Q_1 \otimes_r Q_2$ in $\mathcal{F}$ is at most

$$\sum_{F_1, \ldots, F_r \in \mathcal{F}_{(Q_1)} + 1} La(\bigcap_{i=1}^r F_i, P_{(Q_1)}(Q_1) \cdot La(n - \bigcup_{i=1}^r F_i, P_{(Q_2)}(Q_2) + 1, Q_2). \tag{1}$$

If $r \geq 2$, then grouping the summands in (1) according to the pair $(\bigcap_{i=1}^r F_i, \bigcup_{i=1}^r F_i)$ we obtain

$$La(n, P_{(Q_1 \otimes_r Q_2)} + 1, Q_1 \otimes_r Q_2) \leq \gamma^r(\mathcal{F}_{(Q_1)} + 1) \cdot w,$$

16
where the \((i, j)\)th coordinate of \(w\) is \(La(i, P_l(Q_1), Q_1) \cdot La(n-j, P_l(Q_2)+1, Q_2)\). Clearly, we have
\[
\gamma^r(F_{l(Q_1)+1}) \cdot w \leq n^2 \max_{i,j} \gamma^r_{i,j}(F_{l(Q_1)+1}) w(i, j) \leq n^{2r+2} \max_{i,j} \gamma^r_{i,j} \left( \left\lfloor \frac{n}{(i+j)/2} \right\rfloor \right) w(i, j),
\]
where the last inequality follows from Theorem 4.1. We can calculate the value \(i, j,\) upper bound of part (a)
we know that there exist two families \(F_1, F_2 \subseteq 2^{[r]}\) and \(F_2, n-j^* \subseteq 2^{[n-j^*]}\), both unions of full levels, integers \(k_1, k_2\) and constants \(C_1, C_2\) such that \(C_1(i^*)^k c(Q_1, F_1, i^*) \geq La(i^*, P_l(Q_1), Q_1)\) and \(C_2(j^*)^k c(Q_2, F_2, n-j^*) \geq La(n-j^*, P_l(Q_2), Q_2)\) hold. Therefore by the upper bound already proven, we know that \(La(n, P_l(Q_1 \otimes Q_2)+1, Q_1 \otimes Q_2)\) is at most \(n^{2r+2}C_1(i^*)^k C_2(j^*)^k \gamma^r_{i,j} \left( \left\lfloor \frac{n}{(i+j)/2} \right\rfloor \right) La(i^*, P_l(Q_1), Q_1) La(n-i^*, P_l(Q_2), Q_2)\).

If \(F_{1,i^*}\) consists of levels of set sizes \(h_1, \ldots, h_{l(Q_1)}\) and \(F_{2,n-i^*}\) consists of levels of set sizes \(h_1', \ldots, h_{l(Q_2)}'\), then for the family
\[
F := \left( \left\lfloor \frac{n}{h_1} \right\rfloor \right) \cup \ldots \left( \left\lfloor \frac{n}{h_{l(Q_1)}} \right\rfloor \right) \cup \left( \left\lfloor i^* \right\rfloor + \left\lfloor j^* \right\rfloor + h_1' \right) \cup \ldots \cup \left( \left\lfloor j^* \right\rfloor + h_{l(Q_2)}' \right)
\]
we have \(c(Q_1 \otimes Q_2, F) \geq \gamma^r_{i,j} \left( \left\lfloor \frac{n}{(i+j)/2} \right\rfloor \right) La(i^*, P_l(Q_1), Q_1) La(n-i^*, P_l(Q_2), Q_2)\). Therefore with \(k = 2r + 2 + k_1 + k_2\) the family \(F\) shows that Conjecture 1.7 almost holds for the pair \(P_l(Q_1 \otimes Q_2)+1, Q_1 \otimes Q_2)\).

If \(r = 1\), then \(\bigcup F_1 = \bigcap F_1 = F_1\), so (II) becomes
\[
\sum_{F \in F_{l(Q_1)+1}} La(|F|, P_l(Q_1), Q_1) \cdot La(n-|F|, P_l(Q_2)+1, Q_2).
\]
We can apply Corollary 3.2 with \(l = k = 1\) and \(w(i) = La(i, P_l(Q_1), Q_1') \cdot La(i, P_l(Q_2), Q_2')\) to obtain
\[
La(n, P_l(Q_1 \otimes Q_2)+1, Q_1 \otimes Q_2) \leq \max_{0 \leq i \leq n} \left\{ \left( \left\lfloor \frac{n}{i} \right\rfloor \right) La(i, P_l(Q_1), Q_1') La(n-i, P_l(Q_2), Q_2') \right\}
\]
as required.

As the proofs are almost identical we only show the 'strongly holds' case of the furthermore part of (b). Suppose that the above maximum is obtained when \(i\) takes the value \(i^*\). We know that there exist two families \(F_{1,i^*} \subseteq 2^{[r]}\) and \(F_{2,n-i^*} \subseteq 2^{[n-i^*]}\), both unions of full levels, such that \(c(Q_1, F_{1,i^*}) = La(i^*, P_l(Q_1), Q_1)\) and \(c(Q_2, F_{2,n-i^*}) = La(n-i^*, P_l(Q_2), Q_2)\) hold. If \(F_{1,i^*}\) consists of levels of set sizes \(j_1, \ldots, j_{l(Q_1)}\) and \(F_{2,n-i^*}\) consists of levels of set sizes \(j_1', \ldots, j'_{l(Q_2)}\), then for the family
\[
F := \left( \left\lfloor \frac{n}{j_1} \right\rfloor \right) \cup \ldots \left( \left\lfloor \frac{n}{j_{l(Q_1)}} \right\rfloor \right) \cup \left( \left\lfloor i^* \right\rfloor + j_1' \right) \cup \ldots \cup \left( \left\lfloor i^* \right\rfloor + j'_{l(Q_2)} \right)
\]
we have \(c(Q_1 \otimes Q_2, \mathcal{F}) = \binom{n}{i} La(i^*, P_{l(Q_1)}, Q_1) La(n - i^*, P_{l(Q_2)}, Q_2)\). \(\Box\)

**Proof of Theorem 1.10.** The proof goes very similarly to the proof of Theorem 1.9. Let us consider the canonical partition of a \(P_{l(Q \otimes r) + 1}\)-free family \(\mathcal{F} \subseteq 2^{[n]}\). Then in any copy of \(Q \otimes r\) in \(\mathcal{F}\), if \(F_1, \ldots, F_r\) correspond to the \(r\) top elements forming an antichain, we must have \(F_1, \ldots, F_r \in \mathcal{F}_{l(Q) + 1}\). Also, if a copy of \(Q \otimes r\) contains \(F_1, \ldots, F_r\), then the sets corresponding to the other elements of the poset must be contained in \(\bigcap_{l=1}^{r} F_l\). Then the number of copies of \(Q \otimes r\) in \(\mathcal{F}\) that contain \(F_1, \ldots, F_r\) is at most \(La(j, P_{l(Q) + 1}, Q)\). If \(r \geq 2\), we obtain

\[
c(Q \oplus r, \mathcal{F}) \leq \beta^r(\mathcal{F}_{l(Q)+1}) \cdot w,
\]

where the \(j\)th coordinate of \(w\) is \(La(j, P_{l(Q) + 1}, Q)\). Clearly we have \(\beta^r(\mathcal{F}_{l(Q)+1}) \cdot w \leq n \max_i \beta^r_i(\mathcal{F}_{l(Q)+1}) w(i) \leq n^{2r+2} \max_i \beta^r_i(\binom{[n]}{j(i,r,i,n)}) w(i)\), where the last inequality follows from Theorem 4.2. We have \(\beta^r_i(\binom{[n]}{j(r,i,n)}) = \binom{n}{i} \beta^r_0(\binom{[n-i]}{j(r,i,n) - i})\) by picking the intersection of size \(i\) first.

To see the further part of (a), let \(i^*\) be the value of \(i\) for which the above maximum is attained. Then if \(\mathcal{F}_r = \binom{[n]}{h(i)} \cup \cdots \cup \binom{[n]}{h(i)}\) is a family with \(Cn^k c(\mathcal{F}, \mathcal{F}_r) \geq La(i^*, P_{l(Q)+1}, Q)\), then for the family \(\mathcal{F}^* = \binom{[n]}{h_1} \cup \cdots \cup \binom{[n]}{h_1} \cup \binom{[n]}{j(r,i,n)},\) we have

\[
c(Q \oplus r, \mathcal{F}^*) \geq \beta^r_i(\binom{[n]}{j(r,i,n)}) c(Q, \mathcal{F}_r) \geq \binom{n}{i^*} \beta^r_0(\binom{[n-i^*]}{j(r,i,n) - i^*}) \frac{1}{Cn^k} La(n, i^*, Q),
\]

therefore \(\mathcal{F}^*\) with \(C' = C\) and \(k' = 2r + 2 + k\) shows that Conjecture 1.7 almost holds for the pair \(P_{l(Q) + 2}, Q \oplus r\).

If \(r = 1\), then \(|\cap F_1| = |F_1|\), so applying Corollary 3.2 with \(l = k = 1\) we obtain

\[
c(Q \oplus 1, \mathcal{F}) \leq \sum_{F \in \mathcal{F}_{l(Q)+1}} La(|F|, P_{l(Q)+1}, Q) \leq \max_{0 \leq i \leq n} \left\{ \binom{n}{i} La(i, P_{l(Q)+1}, Q) \right\}.
\]

The proof of the further part of (b) is analogous to the previous ones and is left to the reader. \(\Box\)

**Proof of Corollary 1.11.** We proceed by induction on the number of levels. The base case is guaranteed by Sperner’s Theorem 1.1. The inductive step follows by applying Theorem 1.10 as \(K_{r_1, \ldots, r_l} = K_{r_1, \ldots, r_{l-1}} \oplus r_l\). \(\Box\)

**Proof of Corollary 1.12.** We proceed by induction on the number of levels. The base case is guaranteed by Sperner’s Theorem 1.1. Suppose the statement has been proved for all complete multipartite posets satisfying the condition with height smaller than \(l\) and consider \(K_{r_1, r_2, \ldots, r_l}\). We know that there exists an \(i\) with \(1 \leq i \leq l\) such that \(r_i = 1\). If \(1 < i < l\), then the inductive step will follow by applying the further part of Theorem 1.9 to
\( Q_1 = K_{r_1,\ldots,r_{l-1}} \) and \( Q_2 = K_{r_{l+1},\ldots,r_l} \). If \( i = l \), then the inductive step will follow by applying the furthermore part of Theorem 1.10 to \( Q = K_{r_1,\ldots,r_{l-1}} \) and \( r = 1 \). The case \( i = 1 \) follows from \( c(K_{r_1,\ldots,r_l}, F) = c(K_{r_1,\ldots,r_l}, F) \), where \( F = \{[n] \mid F : F \in F \} \).

**Proof of Theorem 1.12** We only give the sketch of the proof as it is very similar to previous ones. Consider a \( P_{l+3} \)-free family \( F \subseteq 2^n \) and its canonical partition. If \( l = 1 \), then we count the number of copies of \( K_{r_1,\ldots,r_l} \) according to the set \( F \in F_2 \) that plays the role of the middle element of \( K_{r_1,\ldots,r_l} \). The number of copies that contain \( F \) is not more than \( \left( \left\lfloor \frac{|F|}{l} \right\rfloor \right) \left( \left\lfloor \frac{n-|F|}{s} \right\rfloor \right) \). Applying Corollary 3.2 with \( l = k = 1 \) and \( w(i) = \left( \left\lfloor \frac{i}{r_2} \right\rfloor \right) \left( \left\lfloor \frac{n-i}{s} \right\rfloor \right) \) yields \( c(K_{r_1,\ldots,r_l}, F) \leq \max_i \left( \left\lfloor \frac{n}{i} \right\rfloor \right) \left( \left\lfloor \frac{n-i}{s} \right\rfloor \right) \). Let \( i^* \) be the value of \( i \) for which this maximum is attained. Then the family \( \left( \left\lfloor \frac{n}{i^*} \right\rfloor \right) \cup \left( \left\lfloor \frac{n}{i^*} \right\rfloor \right) \cup \left( \left\lfloor \frac{n}{i^*} \right\rfloor \right) \) contains exactly that many copies of \( K_{r_1,\ldots,r_l} \).

If \( l \geq 2 \), then we count the number of copies of \( K_{r_1,\ldots,r_{l-1}} \) according to the sets \( F_2 \in F_2 \) and \( F_{l+1} \in F_{l+1} \) playing the role of the elements on the second and \( (l+1) \)st level of \( K_{r_1,\ldots,r_{l-1}} \). For a fixed pair \( F_2 \in F_2 \) and \( F_{l+1} \in F_{l+1} \) with \( F_2 \subseteq F_{l+1} \) the number of copies of \( K_{r_1,\ldots,r_{l-1}} \) containing \( F_2 \) and \( F_{l+1} \) is at most \( \left( \left\lfloor \frac{|F_2|}{l} \right\rfloor \right) \left( \left\lfloor \frac{n-|F_2|}{s} \right\rfloor \right) \left( \left\lfloor \frac{n-|F_{l+1}|}{s} \right\rfloor \right) \) \(\text{La}(F_{l+1} - |F_2|, P_{l+1}, P_{l-2}) \) is given by Theorem 1.2. So we can apply Corollary 3.2 with \( l = k = 2 \) and \( w(i,j) = \left( \left\lfloor \frac{i}{r_2} \right\rfloor \right) \left( \left\lfloor \frac{n-i-j}{s} \right\rfloor \right) \) \(\text{La}(j-i, P_{l-1}, P_{l-2}) \) to obtain \( c(K_{r_1,\ldots,r_{l-1}}, F) \leq \max_i \left( \left\lfloor \frac{n}{i} \right\rfloor \right) \left( \left\lfloor \frac{n-i}{s} \right\rfloor \right) \left( \left\lfloor \frac{n-j}{s} \right\rfloor \right) \) \(\text{La}(j-i, P_{l-1}, P_{l-2}) \) which contains \( i^* \) and \( j^* \) for which this maximum is attained. Then the family consisting of \( \left( \left\lfloor \frac{n}{i^*} \right\rfloor \right), \left( \left\lfloor \frac{n}{j^*} \right\rfloor \right), \left( \left\lfloor \frac{n}{j^*} \right\rfloor \right) \) and the \( l-2 \) full levels determined by Theorem 1.2 contains exactly that many copies of \( K_{r_1,\ldots,r_{l-1}} \).

There are several other complete multi-partite posets for which one can determine the levels that form an almost optimal family. For example, using Theorem 4.2 (a) one can prove that \( \text{La}(n, P_3, K_{p,2}) \leq n \text{c}(K_{p,2}, F) \) where \( F = \left( \left\lfloor \frac{n}{i} \right\rfloor \right) \cup \left( \left\lfloor \frac{n}{j} \right\rfloor \right) \) with \( i = \left( \frac{2^p + 2}{3 + 2^p} + o(1) \right) n \) and \( j = \left( \frac{2^p + 2}{3 + 2^p} + o(1) \right) n \). In particular \( \text{La}(n, P_3, K_{p,2}) = 2^{(c_p + o(1))n} \), where \( c_p = \frac{2^p + 2}{3 + 2^p} + h(\frac{2^p}{3 + 2^p}) + \frac{3}{3 + 2^p} h(2/3) \).

![Figure 3: The Hasse diagrams of the posets B⁺ and B++]
Let us finish this section by some remarks about $K_{2,2} = B$ as there exist several extremal results concerning $B$. Let us consider the following two posets that contain $B$: $B^+$ and $B^{++}$ have five elements $a,b,c,d,e$ such that $a < B_+ c,e$ and $b < B_+ c,d$ and also $d < B_+ e$, while $a,b < B^{++} c,d$ and $d < B^{++} e$. By results of DeBonis, Katona, and Swanepoel and Methuku and Tompkins [20] we know that $La(n, B, P_1) = La(n, B^+, P_1) = \left( \binom{n}{\lfloor n/2 \rfloor} + \binom{n}{\lfloor n/2 \rfloor + 1} \right)$, and as $B^{++}$ contains a copy of $B^+$ we have $La(n, B^+, P_1) \leq La(n, B^{++}, P_1)$. It is natural to ask how many copies of $B$ can a $B^+$-free or $B^{++}$-free family in $2^{[n]}$ contain, especially that the largest $B^{+-}$ family does not contain any. Obviously, a $P_3$-free poset is both $B^+$-free and $B^{++}$-free, therefore we obtain the inequality $La(n, P_3, B) \leq La(n, B^+, B) \leq La(n, B^{++}, B)$. The next proposition shows that these functions are asymptotically equal.

**Proposition 4.3.**

$$La(n, P_3, B) \leq La(n, B^+, B) \leq La(n, B^{++}, B) = (1 + o(1)) La(n, P_3, B).$$

**Proof.** The first two inequalities are true by definition. Note that $La(n, P_3, B) = 2^{(c_2 + o(1))n}$, where $c_2 = 10/7 + h(4/7) + 3h(2/3)/7$ by the remarks made after the proof of Theorem 1.13.

Let $F \subseteq 2^{[n]}$ be $B^{++}$-free, and consider its canonical partition (note that $P_3$ contains a copy of $B^{++}$, thus $F$ is $P_3$-free).

Consider first the family $S \subseteq F_2$ of sets that appear in 4-chains in $F$ (they must be the second smallest in those chains). Note that if $S \in S$ with $F_1 \subseteq S \subseteq F_3 \subseteq F_4$, then $S$ is not comparable to any other set $F$ of $F$ as $F,F_1,S,F_3,F_4$ would form a copy of $B^{++}$ both if $S \subset F$ or $F \subset S$. Therefore every set $S \in S$ is contained in at most one copy of $B$ in $F$. As $S \subseteq F_2$ is an antichain, we obtain $c(B,F) - c(B,F \setminus S) \leq \left( \binom{n}{\lfloor n/2 \rfloor} \right)$.

Clearly, $F' = F \setminus S$ is $P_3$-free. Let us consider its canonical partition and denote the resulting antichains by $F'_1,F'_2,F'_3$. Let $S' \subseteq F'_2$ be the family of middle sets of all 3-chains in $F'$. We know that for any $S \in S'$ there exist $F'_1,F'_3 \supseteq F'$ with $F'_1 \not\subset S \subsetneq F'_3$. Also, there cannot exist $F''_1,F''_3$ with $F'_1 \subset S \subsetneq F'_3$ as then $F'_1,F''_3,S,F'_{3''}$ would form a copy of $B^{++}$. So either there is a unique set $F'$ that contains $S$ and potentially several sets that are contained in $S$ or there exists a unique $F'$ contained in $S$ and several sets containing $S$. In the former case, if $S$ is contained in a copy of $B$, it can only be one of the top sets. Furthermore, if a copy of $B$ contains $S$, then it contains $F'$ as otherwise this copy could be extended by $F'$ to form a $B^{++}$. As the sets contained in $S$ form an antichain (they are a subfamily of $F'_1$), we obtain that the number of copies of $B$ containing $S$ is at most $\left( \binom{|S|}{\lfloor |S|/2 \rfloor} \right)$. Similarly, if $S$ contains exactly one other set of $F'$, then the number of copies of $B$ containing $S$ is at most $\left( \binom{n-|S|}{\lfloor (n-|S|)/2 \rfloor} \right)$. So introducing $w(i) = \max\{ \left( \binom{i}{\lfloor i/2 \rfloor} \right), \left( \binom{\lfloor (n-i)/2 \rfloor}{\lfloor (n-i)/2 \rfloor} \right) \}$ we obtain that the total number of copies containing at least one element of $S'$ is at most $\sum_{S \subseteq S'} w(|S|)$. By the special case $k = l = 1$ of Corollary 3.2 we obtain that this expression is maximized over all antichains when $S$ is a full level of $2^{[n]}$.  

20
The weight function $w$ is symmetric, i.e. $w(i) = w(n - i)$ holds for any $i$, therefore it is enough to maximize $\binom{n}{i} w(i)$ over $n/2 \leq i \leq n$. It is a routine exercise to see that $\binom{n}{i} \left( \frac{1}{2} \right)$ is maximized when $i = (4/5 + o(1))n$. Therefore the number of copies of $B$ that contain an element of $S'$ is at most $2^{h(4/5) + 8/5 + o(1)}$. We obtained that
\[
c(B, \mathcal{F}) \leq c(B, \mathcal{F} \setminus (S \cup S')) + \binom{n}{\lfloor n/2 \rfloor} + 2^{h(4/5) + 8/5 + o(1)} \\
\leq La(n, P_3, B) + \binom{n}{\lfloor n/2 \rfloor} + 2^{h(4/5) + 8/5 + o(1)} \\
= (1 + o(1))La(n, P_3, B),
\]
as $h(4/5) + 8/5 = 2.3219... < c_2$. 

5 Remarks

One can define an even more general parameter $La_R(P, Q)$. For three posets, $R, P$ and $Q$ we are interested in the maximum number of copies of $Q$ in subposets $R'$ of $R$ that do not contain $P$. Analogously to what we had for set families, we say that $R' \subseteq R$ is a copy of $Q$ in $R$ if there exists a bijection $\phi : Q \to R'$ such that whenever $x \leq Q x'$ holds, then so does $\phi(x) \leq_{R'} \phi(x')$. Let $c(Q, R)$ denote the number of copies of $Q$ in $R$ and for any three posets $R, P$ and $Q$ we define
\[
La_R(P, Q) = \max \{ c(Q, \mathcal{F}) : R' \subseteq R, c(P, R') = 0 \},
\]
and for a poset $R$ and families of posets $\mathcal{P}, \mathcal{Q}$ let us define
\[
La_R(\mathcal{P}, \mathcal{Q}) = \max \left\{ \sum_{Q \in \mathcal{Q}} c(Q, R') : R' \subseteq R, \forall P \in \mathcal{P} \ c(P, R') = 0 \right\}.
\]

Note that $La(n, P, Q) = La_{B_n}(P, Q)$, where $B_n$ is the poset with elements of $2^{[n]}$ ordered by inclusion. Very recently Guo, Chang, Chen, and Li [14] introduced $La_R(Q, P_1)$, as a general approach to forbidden subposet problems. That is to solve the analogous question in a less complicated structure like the cycle, chain or double chain, and then to apply an averaging argument.

In many parts of Theorem [13] the construction yielding the lower bound that matches the upper bound contained the empty set and/or the set $[n]$. One might wonder whether the $La$-function remains the same if we do not allow these elements to be included. In other words, if $B_{\neg n}$ denotes the subposet of $B_n$ with $\emptyset$ and $[n]$ removed, then how $La_{B_{\neg n}}(\lor, P_2)$ relates to $La(n, \lor, P_2)$, $La_{B_{\neg n}}(B, P_3)$ to $La(n, B, P_3)$ and so on. The $\{\lor, \land\}$-free construction...
\((\binom{n}{\lfloor \frac{n}{2} \rfloor}) \cup \{F \cup \{n\} : F \in (\binom{n}{\lfloor \frac{n}{2} \rfloor})\} \) and the \(B\)-free construction \((\binom{n-1}{\lfloor \frac{n-1}{2} \rfloor}) \cup \{F \cup \{n-1\} : F \in (\binom{n-1}{\lfloor \frac{n-1}{2} \rfloor})\}\) show that

- \((\binom{n}{\lfloor \frac{n}{2} \rfloor}) \leq La_{B_n}(\cup, P_2) = La_{B_n}(\bigwedge, P_2) \leq \left(\binom{n}{\lfloor \frac{n}{2} \rfloor}\right),\)
- \((\binom{n-1}{\lfloor \frac{n-1}{2} \rfloor}) \leq La_{B_n}(B, P_3) \leq \left(\binom{n}{\lfloor \frac{n}{2} \rfloor}\right).\)

There is a longstanding (folklore) conjecture which would imply the existence of constructions in both cases that asymptotically match the upper bounds. Let \(M\) be a family of sets with the property that for every \(K \in \binom{[n]}{k}\) there exists at most one set \(M \in \mathcal{M}_{k+1}\) with \(K \subseteq M\). Obviously, for any such set we have \(|\mathcal{M}_{k+1}| \leq \binom{n}{k}/(k+1)\) and \(R_{k+1} := M_{k+1} \cup \binom{[n]}{k}\) is \(\mathcal{V}\)-free with \(c(P_2, R_{k+1}) = (k+1)|M_{k+1}|\). It is conjectured that there exists a family \(\mathcal{M}_{n/2+1}\) with the above property such that \(|\mathcal{M}_{n/2+1}| = (1 - o(1))(\binom{n}{n/2})/(\lfloor n/2 \rfloor + 1)\) holds.

Similarly, writing \(\overline{M}_{n-k+1}\) for \([n] \setminus M : M \in \mathcal{M}_{n-k+1}\) the construction \(T_k := \mathcal{M}_{k+1} \cup \binom{[n]}{k}\) is \(B\)-free. The above conjecture would yield \(c(P_3, T_{n/2}) = (1 - o(1))\binom{n}{n/2}\).

In Section 4, we proved that apart from a polynomial factor Conjecture \([7]\) holds for complete multi-level posets, i.e. there exists a sequence \(F_n\) of families that consists of full levels such that \(La(n, P_{l+1}, K_{r_1, r_2, \ldots, r_l}) \leq n^k c(F_n, K_{r_1, r_2, \ldots, r_l})\) for some constant \(k = k(K_{r_1, r_2, \ldots, r_l})\). To improve this result or to completely get rid of the polynomial factor one would need to improve Theorem \([8]\) or rather to determine the intersection profile polytope of antichains.
