ABSTRACT

Purpose: The research aims to investigate agricultural production and its influence on India’s economic growth.

Methods: The ADF test has been used to determine variable stationarity. Using secondary data from 1991 to 2020, the ARDL Model was used to estimate the long-run and short-run links between agricultural production and economic growth.

Findings: Our empirical findings reveal that the GCF and inflation rate are negatively correlated with economic growth in the short and long term. In contrast, all other factors have a positive link with economic growth.

Research Implication: We believe that The government has employed various tactics to maintain farm prices and profits. They imposed production limitations and subsidy programs that made direct payments to farmers. It is more efficient for the government to supply farmers with the required inputs, and farmers can use those cost-effective inputs in various agricultural operations.

Future Research Suggestion: The research has certain flaws because it only looks at five different crops and evaluates their influence on economic expansion over the previous three decades. The new study, with its many variables and long year, presents an opportunity to boost India’s agricultural output, despite the fact that it has several flaws.
Keywords: Economic growth; agricultural productivity; ADF; ARDL; GCF.

ABBRVIATIONS

ADF : Augmented Dickey Fullar Test
ARDL: Auto regression Distributed Logg Model
GCF : Gross Capital Formation

1. INTRODUCTION

1.1 Agricultural Productivity Overview

India is the world's largest populated country, with 1.27 billion people. With a size of 3.288 million square kilometres, it is the world's sixth-biggest country. It has a 7,500-KM-long coastline. India is a varied country with more than 22 main languages and 415 dialects. The nation is home to great agro-ecological variety, with the tallest mountain range in the world, the Himalayas, in the north, the Thar sands in the occident, the Gangetic delta in the occident, and the Deccan Plateau to the south. India is the world's most fabulous producer of fruits and vegetables. It's also a significant producer of spices, seafood, poultry, cattle, and plantation crops. With a GDP of $ 2.1 trillion, India is the world's third-largest economy after the United States and China.

India's economic growth is predicted to rise by 8.0 or 8.5 per cent in the fiscal year 2022-23 (Economic Survey, 2021-22) due to stronger performance in both industry and services [1-3]. India has the world's fifth-largest economy in nominal GDP ($ 2.94 trillion) and third-largest in terms of purchasing power parity ($ 10.51 trillion). Agriculture accounted for 16.07 % of GDP in 2021 (WDI, 2021) and employed 59% of the country's overall workforce. Agriculture, along with its linked sectors, is India's most important source of income. 70% of its rural families are still largely dependent on agriculture for a living, with 82 percent of farmers being small and marginal. Total food grain production was predicted to be 315 million tonnes MT in 2020-21 (Indiastat, 2021). India is the world's greatest producer (25 percent of global production), the world's greatest consumer (27 percent of global consumption), and the world's greatest importer (14%). India's annual milk output was 165 million tonnes (MT) in 2017-18, making it the world's greatest producer of milk, jute, and pulses and home to the world's second-largest cow population of 190 million in 2012. It is the world's second-largest manufacturer of rice, wheat, sugarcane, cotton, and groundnuts. The second-largest manufacturer of fruits and vegetables in China, accounting for 10.9 percent and 8.6 percent, respectively.

Ahmad [4] the researcher studied Pakistan's agricultural productivity. ARDL determined total factor productivity's impact (TFP). This study included five variables from 1965-2009 Pakistan economic surveys. Fertilizer, human capital, and agricultural funding can enhance productivity. Short- and long-term data show cropped area did not grow. Human capital and fertiliser affect long- and short-term production flexibility. Research concluded that increasing farm productivity requires qualified personnel and food security.

Ali (2012) agriculture is crucial to Pakistan's economic success. A simple regression approach changed the relevance of livestock, main crops, fisheries, minor crops, and GDP. Agriculture sub-sector and economic growth were studied using OLS. This study used seven variables. Statistics show a strong link between forestry and GDP. All independent factors were significantly related to GDP. They boosted GDP, 90% of crops and animals contribute to agricultural production, whereas fisheries and forests contribute less due to lack of investment.

Awan and Aslam [5] Pakistan's agriculture impact was measured. They said Pakistan has low output due to little investment, insufficient food due to population, and ineffective management due to a low education system. Low output and bad quality make Pakistan's exports worthless. Pakistan should eliminate agrarian difficulties. Mechanization, irrigation, and packing quality should be improved.

Kulshrestha & Agrawal [6] this study looked at agricultural production and its influence on India's economic growth. The study found that if the agricultural output (explanatory variables) in India had not increased, the country's economic growth would have suffered.

Faridi [7] researchers studied agricultural exports' impact on Pakistan's economy. Researchers examined the impact of agricultural exports on economic growth using secondary data from 1972 to 2008. Increasing agricultural
exports would hamper economic growth, the study found. Exports boost agriculture. Agricultural exports inhibit economic growth and development, but non-agricultural exports boost economic growth. The study recommended promoting non-agricultural and textile products.

Awan and Naseem [8] the researcher explained government spending’s impact on Pakistan’s economy. They used 2005-2015 data. The OLS technique and linear regression model were used to analyse and interpret the data. Health, education, investment, and saving rates were independent variables. Since educated workers (human capital) are unemployed, education and health severely affect Pakistan’s GDP. Investing and saving still help. Skill development improves human capital’s efficiency and production, boosting economic growth.

Chandio et al. [9] analyzed Pakistan's agriculture sector's share and GDP growth rate from 1971 to 2015. Agriculture affects all sectors and GDP, as shown by ARDL. The link between agricultural production and economic growth affected GDP. They stressed the need for innovative technology in Pakistan's agriculture industry. This will strengthen Pakistan's economy.

Khan et al. [10,11] researchers studied agricultural value addition and poverty alleviation. Increasing agricultural output reduces poverty. From 1972 until 2013, secondary data was used. The Johansen co-integration model examined agriculture, poverty alleviation, and their determinants with GDP. According to the study, livestock and labour reduce poverty. Poverty hurts economic growth. Agricultural value-added boosts economic growth, according to the study.

Muhammad (2016) assessed Pakistan’s agriculture sector’s GDP growth. In his investigation, he found that livestock, important crops, and other crops make for 23.5% of agriculture’s GDP. His studies showed a strong link between agriculture and GDP growth since the business offers farmers jobs and incentives. It affects food and pesticide supplies. Agriculture positively affects economic growth.

Awan and Mukhtiar (2020) this research study examines agriculture’s impact on Pakistan’s economy. ADF tests variable stationarity. The ARDL Model was used to evaluate long- and short-run relationships between agricultural production and economic growth from 1994 to 2017. The GCF and inflation rate are inversely connected with short- and long-term economic growth. All other elements are pro-growth. We think the government should raise farm spending and employ new technology to boost production.

As shown in a review of literature, economic growth depends on agriculture's positive and negative impact. We’ve studied the relationship between agriculture and economic growth in India, where agriculture is a substantial contributor to GDP but where GPD is low.

According to Oyakhilomen and Zibah [12], agricultural production and economic growth in Nigeria are favourably associated. The boundaries testing (ARDL) technique to co integration is used to analyse time series data on agricultural production, real GDP, interest rate, currency rate, and inflation rate, yielding to the study's primary discovery. Agricultural production positively affects Nigeria’s economic growth both long and short term.

Cao and Birchenall, [13] found that agricultural productivity affects China’s post-reform economic development and sectoral reallocation. Using microeconomic farm-level data and treating labour as highly differentiated inputs, labour input in agriculture reduced by 5% yearly and agricultural TFP climbed by 6.5%. Using a calibrated two sector general equilibrium model, researchers found that agricultural TFP growth a. accounts for most production and employment reallocation toward non-agriculture by contributing as much to aggregate and sectoral economic growth as nonagricultural TFP growth. It affects economic growth by reallocating employees to non-agricultural sectors with rapid physical and human capital buildup.

Awan, and Vashma, [10,11] examined the primary determinant of agricultural sector and the relationship between agriculture economic development and GDP. 1980-2010: 31 observations. Economic variables included GDP and agriculture growth. Pakistani World Bank Metadata were used. The variable association was measured using co integration and vector error correction. Agriculture growth and GDP growth have a statistically significant positive link. Agriculture expansion is crucial for economic growth, according to some [14,15].

3. RESEARCH METHODOLOGY

3.1 Data Types and Sources

This study relied on secondary data. The information was gathered from the World
3.2 Variables Identified and their Meanings

GDP (Gross Domestic Product)  Dependent variable
INF (Inflation Rate)  Independent variable
GCF (Gross Capital Formation)  Independent variable
CC (Coarse cereal)  Independent variable
TFG (Total Foodgrain)  Independent variable

3.3 Formulation of Hypotheses

H0 = Agriculture productivity in India has no positive association with economic growth.
H1: Agriculture productivity has a favorable association with India’s economic growth.

3.4 Econometric Model

This study’s econometric model is as follows:

\[ GDP = \beta_0 + \beta_1 \text{INF} + \beta_2 \text{GCF} + \beta_3 \text{CC} + \beta_4 \text{TFG} + \mu \]  
(1)

Where

GDP stands for Gross Domestic Product.
INF stands for Inflation.
GCF stands for Gross Capital Formation.
TFG stands for Total foodgrain.
CC is abbreviated as coarse cereal.
\( \beta_0 = \text{Interception} \)
\( \beta_1, \beta_2, \beta_3, \beta_4, \beta_5 = \text{Slope Coefficient} \)
Error Term = \( \mu \)

3.5 Autoregressive Distributed Lag Model

The ARDL technique is being used to examine Pakistan’s agricultural production and economic growth. The ARDL bounds testing technique established by Pesaran et al. (1996), Pesaran and Ship (1990), and Pesaran et al. (2001) is elastic, requiring that variables in the model specification be integrated at order 0 or 1, that is, I (0) or I (1). (1). Even with tiny samples, this estimate methodology produces effective results.

In the model, variables can be assigned varying leg lengths. The following is the ARDL equation:

\[ Y_t = \beta_0 + \beta_1 Y_{t-1} + \ldots + \beta_q Y_{t-q} + \alpha_0 X_{t-1} + \alpha_2 X_{t-2} + \ldots + \alpha_k X_{t-k} + \epsilon_t \]  
(2)

The unconstrained vector error model, on the other hand, is shown below

\[ \Delta GDP_t = \gamma_0 + \sum_{i=1}^{p} \gamma_i GDP_{t-i} + \sum_{i=1}^{q} \delta_i INF_{t-i} + \sum_{i=1}^{p} \eta_i GFC_{t-i} + \sum_{i=1}^{q} \eta_i COARSE_{t-i} + \sum_{i=1}^{l} \gamma_i TFG_{t-i} + \mu_t \]  
(3)

The ARDL model, shown in Equation (3), demonstrates the long-run and short run connection between the dependent and independent variables. The intercept term is 0. The short-run coefficients of variables are \( \gamma_0, \gamma_1, \gamma_2, \gamma_3, \gamma_4 \), explanatory variables, whereas the long run co-efficients of variables , and \( t \) is the stochastic error, which includes all missing variables in the equation.

3.6 Short-Run Relationship Error Correction Model

This approach determines the short-run relationship between the GDP and other independent variables. The following is the short-run error correction equation:

\[ \Delta GDP_t = \eta + \delta t + \lambda (ECM)_t + \mu_t \]  
(4)

(EMC-i) The ECM illustrates the short-run influence on the x and y variables and the adjustment rate.

\[ \Delta Y_t = \eta + \delta t + \lambda (ECM-T)_t + \mu_t \]  
(5)

In the equation, \( \delta \) denotes the short-run effect and \( \lambda \) denotes the adjustment speed. Table 6 displays the ECM findings.

4. RESULTS AND DISCUSSION

4.1 Descriptive Statistics

Table 1 reveals that the average GDP growth rate is 5.81 percent, with a standard deviation of 3.11 percent. The average inflation rate (INF) is 7.23, with a standard deviation of 3.23. The mean or average value of gross capital formation (GCF) is 31.78, with a standard deviation of 5.46.
The mean value of cereal is 362.25, with a standard deviation of 61.81, and the mean total food grain value is 2221.33, with a standard deviation of 371.18. Other variables are favorably skewed except for GDP, which is negatively skewed, including Inflation, GCF, cereals, and TFG. The variables' kurtosis statistics show that GCF, core cereal inflation, and total foodgrain are platykurtic (lower peak or short-tailed) since their values are smaller than 3. GDP is leptokurtic (long-tailed or high peak) since its value is greater than three. The results show that the Jarque-Bera P (probability) value of GDP is 0.00, less than 10%; hence, we reject the null hypothesis because it indicates that the data is not normally distributed. Because the Jarque-Bera P-value of Inflation is 0.26, greater than 10%, we accept the null hypothesis because it indicates that the data is normally distributed. As a result, because the Jarque-Bera P-value of all the other variables is greater than 10%, we accept the null hypothesis because the data is normally distributed.

4.2 Correlation Analysis

Except for GCF, all variables are strongly negatively linked with GDP. The variable "gross domestic product" (GDP) is associated positively and combined with INF cereal and total food grain. Only the GCF is positively associated with the GDP (GDP). The identical variables, GCF and GCF, completely depend on one another. Because $r > 0.30$, the relationship between GDP and inflation is negative (-0.07). The connection coefficient between gross capital creation and cereal force is 0.30, and the correlation is moderate from 0.30 < $r < 0.40$.

4.3 Displays the Results of the ADF Test

Table 3 shows the stationary and non-stationary characteristics of the various variables. Time series data must be stationary to avoid erroneous regression analysis since it is impossible to obtain excellent findings and forecasts with a non-stationary series. The augmented Dickey-Fuller test revealed that certain variables are stationary at the level, and others are stationary at the first difference. This means that GDP is integrated at the first difference, and the t-statistic value is -4.37 with a probability value of 0.002. Inflation is likewise stationary at the level with a t-statistic of -5.99 and a probability of 0.00. The gross capital formation (GCF) is integrated at the first difference with the t-statistic value of -5.12, with a probability value of 0.00. The Cereal cereal is stagnant at level (trend and intercept), with a t-statistic of -6.257 and a probability of 0.00. The total food grain stationary at the first difference, with a t-statistic of -9.93 and a probability of 0.00. Time series analysis reveals that all variables are integrated with distinct orders, implying no co-integration among variables so that the ARDL model may be used.

Table 1. Dependent and Independent variable

| Variable      | Mean     | Median   | Maximum | Minimum | Std. Dev. | Skewness | Kurtosis | Jarque-Bera | Probability |
|---------------|----------|----------|---------|---------|-----------|----------|----------|------------|-------------|

Source: Author's calculate Eview-10

Table 4. Bound test results

| Test Statistic | Value | Signif. | I(0) | I(1) |
|----------------|-------|---------|------|------|
| F-statistic    | 11.59758 | 10% | 2.2 | 3.09 |
| k              | 4 | 5% | 2.56 | 3.49 |
|                | 2.5% | 2.88 | 3.87 | |
|                | 1% | 3.29 | 4.37 | |

The bound test for co-integration demonstrates the long-run relationship between the variables. Table 4 displays the results.

The critical values of the upper and lower bounds, I (1) and I(0), are shown in the table above. Because the observed F-statistics value is bigger than the upper bound of F-Statistics, we reject the null hypothesis and thus accept the alternative hypothesis, which states a long-run link between the variables.

4.4 The ARDL Model's Long-Term Relationship

The long-term relationship between the dependent and independent variables is expressed as an equation.

\[
\Delta GDP_t = \sigma_0 + \sum_{i=1}^P \sigma_i GDP_{t-i} + \sum_{i=1}^P \sigma_2 INFL_{t-i} + \sum_{i=1}^P \sigma_3 GFC_{t-i} + \sum_{i=1}^P \sigma_4 COARE_{t-i} + \sum_{i=1}^P \sigma_5 TFG_{t-i} + \epsilon_t \quad (6)
\]

Where \(\sigma\) is the coefficient of the lagged X term. The long-term relationship is provided in.

According to the table above, total food grain is the most relevant variable in the long and short run. The ECM coefficient is -0.009, which is both negative and substantial. This negative and large error correction model coefficient suggests a long-run causal link. The value of ECM reflects the rate at which the system adjusts from disequilibrium to equilibrium. The corrected R² value is 0.95, indicating a 95% variance in GDP (Dependent variable) due to changes in independent factors. The likelihood of the F-statistic is likewise statistically significant at the 5% level of significance, supporting the model's goodness of fit.
Table 5. Shows the findings of the ARDL model

### Case 2: long run relationship

| Variable       | Coefficient  | Std. Error  | t-Statistic | Prob.  |
|----------------|--------------|-------------|-------------|--------|
| Inflation      | -0.548552    | 0.316392    | -1.733773   | 0.1266 |
| GCF            | -0.539742    | 0.273312    | -1.974819   | 0.0889 |
| COARE_CEREAL   | 0.009788     | 0.025494    | 0.383947    | 0.7124 |
| TFG            | 0.006186     | 0.004798    | 1.289218    | 0.2383 |

Author's calculation based on Eviews-10

Fig. 1. Model's stability in short-and long-run connections
4.5 Model Stability

The cumulative sum of recursive residuals (CUSUM) indicates the model's stability in short- and long-run connections between variables. The cumulative total of the recursive residuals graph is shown Fig. 1.

CUSUM Test examines the model's stability by plotting time series on the horizontal axis and residuals on the vertical axis. Fig. 1 demonstrates that CUSUM is inside the 5% critical line range. The graph does not pass this essential limit. As a result, we may infer that the model is stable and there are no significant gaps. At the 5% significance level, this accurate specification model supports the null hypothesis.

5. CONCLUSION

India's growth depends on agriculture [16]. Considering the demonstrate that inflation and GCA (-0.54 percent and -0.53) slowed India's GDP, coarse cereal contributes greatly to GDP growth, hence its cultivation should be prioritised. As the basic diet of most Indians and a positive contributor to GDP, total foodgrain productivity and output must be improved.

Here are some ideas.

a. Farmers need training in contemporary agricultural techniques to increase production and resource efficiency. Regularly monitor their job.

b. Improving irrigation facilities will protect crops from nature.

c. Adequate financing and insurance are needed to boost farming.

d. Storage and marketing facilities should be available to minimise distress sales, which discourage agriculture.

e. Farmers should be encouraged to produce high-quality goods. Fair rates for their products should be guaranteed.
