Abstract—In this paper, we give easily verifiable sufficient conditions for two classes of perturbed linear, passive PDE systems to be well-posed, and we provide an energy inequality for the perturbed systems. Our conditions are in terms of smoothness of the operator functions that describe the multiplicative and additive perturbation, and here well-posedness essentially means that the time-varying systems have strongly continuous Lax-Phillips evolution families. A time-varying wave equation with a bounded multi-dimensional Lipschitz domain is used as an illustration, and as a part of the example, we show that the time-varying systems have strongly continuous evolution families. Every linear, time-invariant, well-posed system $\Sigma_i$ in continuous time, whose input space $U$, state space $X$ and output space $Y$ are Hilbert spaces, can after some technical setup be written in the following familiar-looking form:

$$\Sigma_i : \begin{cases} \dot{x}(t) = A_1 x(t) + B u(t), \\ y(t) = C x(t) + D u(t), \\ x(\tau) = x_\tau, \end{cases} \tag{I.1}$$

where $x(t) \in X$ is the state at time $t$, $u(t) \in U$ is the input, $y(t) \in Y$ is the output, and $A_1$ and $C$ are certain extensions of the main operator $A$ and observation operator $C$. We will describe this class of systems in more detail below, in §II.

The system (I.1) is (scattering) passive if all its trajectories satisfy the following energy inequality, for all $t \geq \tau$:

$$\|x(t)\|_X^2 + \int_\tau^t \|y(s)\|_Y^2 \, ds \leq \|x(\tau)\|_X^2 + \int_\tau^t \|u(s)\|_U^2 \, ds. \tag{I.2}$$

Let $[A_1 \ B \ C \ D]$ be a time-invariant passive linear system on $(U, X, Y)$. In this paper, we prove that

$$\Sigma_l : \begin{cases} P(t) \dot{x}(t) = (A_1 + P(t)G(t)) x(t) + B u(t), \\ y(t) = C x(t) + D u(t), \\ x(\tau) = x_\tau, \end{cases} \tag{I.3}$$

and

$$\Sigma_r : \begin{cases} \dot{x}(t) = (A_1 + P(t) + G(t)) x(t) + B u(t), \\ y(t) = C P(t) x(t) + D u(t), \\ x(\tau) = x_\tau, \end{cases} \tag{I.4}$$

define time-varying well-posed systems (defined later) under certain smoothness conditions on $P(\cdot)$ and $G(\cdot)$, and some of these make the notation ‘l’ for “left”, ‘r’ for “right” more evident; in $\Sigma_l$ we could for instance write

$$\dot{x}(t) = P(t)^{-1} (A_1 x(t) + B u(t)) + G(t) x(t).$$

The particular choice (I.3) – (I.4) has the advantage that the trajectories of both systems satisfy the same energy inequality: for all $t \geq \tau$ in the time interval $J$ of the system,

$$\langle P(t)x(t), x(t) \rangle_X + \int_\tau^t \|y(s)\|_Y^2 \, ds \leq \langle P(\tau)x(\tau), x(\tau) \rangle_X + \int_\tau^t \|u(s)\|_U^2 \, ds + \int_\tau^t \langle P(s)x(s), x(s) \rangle_X \, ds + 2\text{Re} \int_\tau^t \langle P(s)x(s), G(s)x(s) \rangle_X \, ds. \tag{I.5}$$

Our investigation requires that we prove new generation results for evolution families, which is in itself a valuable contribution, since such results are currently rather scarce. The theory in the present paper generalizes the work of Schnaubelt and Weiss [11], and that of Chen and Weiss [2], to a large extent by combining the techniques of these two papers. The exposition here is brief, avoiding duplication of detail through careful referencing. Reading [1] and [2] first is recommended, to obtain needed background and many references.

Based on previous work [3], we use the wave equation on a bounded Lipschitz domain $\Omega \subset \mathbb{R}^n$ to illustrate the applicability of the results of the present paper. This example is an extension of the wave equation in [11] §5, which can handle a moving object inside the domain, but the example cannot be treated with the tools developed in [11]. As an intermediate step, we prove that the wave equation (V.1) below can be written as a “physically motivated” scattering passive system in the sense of Staffans and Weiss [4, 5]. Due to the progress in [3] and [4] after [11], the treatment of the example is somewhat easier in this paper than in [11] §5.

Linear port-Hamiltonian systems [6] are a large class of abstract PDEs with one-dimensional spatial domains, which includes the wave equation (on a string) and various beam equations. The theory in the present paper applies to time-varying port-Hamiltonian systems, in the same way as it applies to the wave equation in [4] see in particular [6] §11.3 and [7] (3.1) and Thm 4.6). In fact, in closely related independent work [8], Jacob and Laasri consider well-posedness (defined slightly differently) of time-varying boundary control systems, using port-Hamiltonian systems as motivating example. There is a considerable methodical overlap between the present paper and [8], and the theory in [8] can likely also cover the example in §V. Finally, we mention that Paunonen

M. Kurula is with Åbo Akademi University, Mathematics and Statistics, Domkyrkotorget 1, 20500 Åbo, Finland (e-mail: mkurula@abo.fi).
and Pohjolainen [10] have studied robust output regulation of periodically time-varying distributed parameter systems.

In [11] we collect the needed background on time-varying well-posed systems and their Lax-Phillips evolution families. Section III contains our evolution-family generation results, in IV we prove well-posedness of (1.3) and (1.4), and in V the paper is concluded with the wave equation example.

II. TIME-VARYING WELL-POSED LINEAR SYSTEMS

In this section, we fix the notation and concepts needed later. We make the following assumptions throughout the paper: By $J \subset \mathbb{R}$ we denote a closed (time) interval of positive length, and we define $\Delta_J := \{(t, \tau) \in J^2 \mid t \geq \tau\}$ (a triangle if $J$ happens to be compact). We identify, e.g., $L^2(J; U)$ with the subspace of $L^2(\mathbb{R}; U)$ consisting of elements with support contained in $J$, and by $P_J$, we denote the orthogonal projection (by truncation) onto $L^2(J; U)$ in $L^2(\mathbb{R}; U)$. The bilateral shift of functions defined on $\mathbb{R}$ is $(S_J u)(\tau) = u(t+\tau)$, and we abbreviate $S^\pm_J := P_{J\pm} S_J$, where $\mathbb{R}_\pm$ are in general closed or open, as fitting for the context. By writing, e.g., $H^1(J; U)$, we more precisely mean $H^1(J^0; U)$, where $J^0$ is the interior of $J$, and by derivatives evaluated at any end points of $J$, we mean the appropriate one-sided derivatives.

Definition II.1. A strongly continuous evolution family on the Hilbert space $X$ with time interval $J$ is a two-parameter family $\mathbb{T}$ defined on $\Delta_J$, such that

1) $\mathbb{T}(t, \tau) \in \mathcal{L}(X)$ for all $(t, \tau) \in \Delta_J$,
2) $\mathbb{T}(t, s) \mathbb{T}(s, \tau) = \mathbb{T}(t, \tau)$ for all $t, s, \tau \in J$: $t \geq s \geq \tau$,
3) $\mathbb{T}(t, t) = I$ for all $t \in J$, and
4) $(t, \tau) \mapsto \mathbb{T}(t, \tau)z$ is in $C(\Delta_J; X)$ for all $z \in X$.

An evolution family $\mathbb{T}$ with time interval $J$ is locally (uniformly) exponentially bounded if for every compact $[a, b] \subset J$, there exist $M, \omega \in \mathbb{R}$, such that

$$\|\mathbb{T}(t, \tau)\| \leq Me^{\omega(t-\tau)}, \quad (t, \tau) \in \Delta_{[a, b]},$$  \hspace{1cm} (II.1)

If there exist $M, \omega \in \mathbb{R}$ with the above property, which are independent of $[a, b]$, then we call $\mathbb{T}$ exponentially bounded.

A family $\{A(t) : X \supset \text{dom} (A(t)) \to X \mid t \in J\}$ of $C_0$-semigroup generators are said to generate $\mathbb{T}$ if

a) $\mathbb{T}(t, \tau) \text{dom} (A(\tau)) \subset \text{dom} (A(t))$ for all $(t, \tau) \in \Delta_J$,
b) for every $\tau \in J$ with $\tau < \sup J$ and every $x_\tau \in \text{dom} (A(\tau))$, the function

$$x(t) := \mathbb{T}(t, \tau)x_\tau, \quad t \in J_\tau := \{t \in J \mid t \geq \tau\},$$

is a solution in $C^1(J_\tau; X)$ of the Cauchy problem

$$\dot{x}(t) = A(t)x(t), \quad t \in J_\tau, \quad x(\tau) = x_\tau.$$  \hspace{1cm} (II.2)

Not all evolution families have generator families in this sense, but a generator family can generate at most one evolution family. If $\mathbb{T}(t+s, s)$ is independent of $s \in J$ for all $t \geq 0$ such that $t+s \in J$, then $\mathbb{T}_{st}^J := \mathbb{T}(t+s, s)$, $t \geq 0$ and $t+s \in J$, can be extended to a unique $C_0$ semigroup on $X$, which is always exponentially bounded, $\|\mathbb{T}_{st}^J\| \leq Me^{\omega t}$ for some $M, \omega \in \mathbb{R}$.

Some of our proofs use duality arguments, and we then need backward evolution families [1 Def. 2.5]. Such are two-parameter families $\mathbb{T}$ defined on $\Delta_J$ with properties 1), 3), 4) in Def. II.1 but 2) is replaced by

$$\mathbb{T}(s, \tau) \mathbb{T}(t, s) = \mathbb{T}(t, \tau), \quad t, s, \tau \in J, \quad t \geq s \geq \tau.$$  

A $C_0$-semigroup generator family $A(t)$, $t \in J$, generates a backward evolution family $\mathbb{T}$ if

$$\mathbb{T}(t, \tau) \text{dom} (A(t)) \subset \text{dom} (A(\tau))$$

for all $(t, \tau) \in \Delta_J$ and for every $t \in J$ with $t > \inf J$ and every $x_t \in \text{dom} (A(t))$, the function

$$x(\tau) := \mathbb{T}(t, \tau)x_t, \quad \tau \in J \cap (-\infty, t]$$

is a strongly continuous (in $X$) solution of the backward-time Cauchy problem

$$\dot{x}(\tau) = -A(\tau)x(\tau), \quad \tau \in J \cap (-\infty, t], \quad x(t) = x_t.$$  

A contraction semigroup is exponentially bounded by $M = 1$ and $\omega = 0$, and the generator of a contraction semigroup is maximal dissipative on $X$, meaning that $\text{Re} \langle Ax, x \rangle \leq 0$ for all $x \in \text{dom} (A)$ and the resolvent set $\rho (A)$ contains the open complex right-half plane $\mathbb{C}_+$. We will prove that (1.3) and (1.4) describe time-varying well-posed linear systems in the sense of [1 Def. 3.2]:

Definition II.2. A (time-varying) well-posed system $\Sigma$ on a closed time interval $J \subset \mathbb{R}$, with Hilbert input, state and output spaces $(U, X, Y)$, is a quadruple of linear operator families defined for $(t, \tau) \in \Delta_J$, mapping

$$\mathbb{T}(t, \tau) : X \to X, \mathbb{F}(t, \tau) : L^2(J; U) \to L^2(J; Y),$$

$$\Phi(t, \tau) : L^2(J; U) \to X, \Psi(t, \tau) : X \to L^2(J; Y)$$

(II.3)

boundedly, which have the following additional properties:

1) $\mathbb{T}$ is an evolution family on $X$ with time interval $J$,
2) the other families are causal in the sense that

$$\Phi(t, \tau) = \Phi(t, \tau)\mathbb{P}_{[t, \tau]},$$
$$\Psi(t, \tau) = \mathbb{P}_{[t, \tau]}\Psi(t, \tau)$$

and

$$\mathbb{F}(t, \tau) = \mathbb{P}_{[t, \tau]}\mathbb{F}(t, \tau)\mathbb{P}_{[t, \tau]},$$  \hspace{1cm} (II.4)

3) all four families are locally uniformly bounded,
4) and they encode the linearity of the system, so that for all $t, s, \tau \in J$ with $t \geq s \geq \tau$:

$$\Phi(t, \tau) = \Phi(t, s) + \mathbb{T}(t, s)\Phi(s, \tau),$$
$$\Psi(t, \tau) = \Psi(t, s)\mathbb{T}(s, \tau) + \Psi(s, \tau),$$

and

$$\mathbb{F}(t, \tau) = \mathbb{F}(t, s) + \mathbb{F}(s, \tau) + \Psi(s, \tau)\Phi(s, \tau).$$  \hspace{1cm} (II.5)

A well posed system is called time invariant if $J = \mathbb{R}_+$ and the following are all independent of $s \geq 0$, for $t \geq 0$:

$$\mathbb{T}_t^s := \mathbb{T}(t+s, s),$$
$$\mathbb{F}_t^s := S_s\mathbb{F}(t+s, s)S_{-s},$$
$$\Phi_t^s := \Phi(t+s, s)S_{-s}, \quad \Psi_t^s := S_s\Psi(t+s, s).$$  

The four operator families of a well-posed system $[\mathbb{T}, \Phi, \Psi]$ are strongly continuous in $X$; see [1 Prop. 3.5]. By a trajectory of a well-posed system on $J$ with initial state $x_\tau$ at time $\tau \in J$,
\[ \tau < \sup (J) \], and input \( u \in L^2_{\text{loc}}(J; U) \), we mean the triple
\( (u, x, y) \in L^2_{\text{loc}}(J; U) \times C(J; X) \times L^2_{\text{loc}}(J; Y) \):
\[ x(t) = T(t, \tau)x_\tau + \Phi(t, \tau)u \quad \text{and} \quad P_{[\tau, \iota]}y = \Psi(t, \tau)x_\tau + \Phi(t, \tau)u, \quad t \in J; \]
see [1] p. 282. In particular, a trajectory of a well-posed system is uniquely determined by its initial state \( x_\tau \) and input \( u \). Classical trajectories of \( \left[ T, \Phi, \Psi \right] \) are such that \( (u, x, y) \in C(J; U) \times C^1(J; X) \times C(J; Y) \).

The class of time-invariant well-posed systems in Def. II.2 coincides with the standard class; take \( a = 0 \) in the definitions of the time-invariant operators and see [1] §2.8.

In this paper, we will be interested in evolution family generator families of the form \( A_t(t) = P(t)^{-1}A + G(t) \) and \( A_s(t) = AP(t) + G(t) \), where \( A \) generates a contraction semigroup on \( X \). By the Lumer-Phillips theorem [12 II.3.5], \( A \) is maximal dissipative.

We will apply the generation results in [III] to the generator of the Lax-Phillips semigroup
\[ \mathcal{S}_1 := \begin{bmatrix} I & \Phi_1 & \Phi \tau & \\ 0 & I & 0 & 0 \\ 0 & 0 & I & \Phi \tau \\ 0 & 0 & 0 & I \end{bmatrix}, \quad t \geq 0, \] of a passive time-invariant system \( \left[ T, \Phi, \Psi \right] \). Due to passivity, this is a contraction semigroup on the space \( \mathcal{H} := L^2(\mathbb{R}_+; Y) \times X \times L^2(\mathbb{R}_+; U) \) with generator [1] Prop. 3.1
\[ \mathcal{A}(y, x_0, u) = ( y', A_{-1}x_0 + Bu(0), u'), \]
\[ \text{dom} (\mathcal{A}) = \{(y, x_0, u) \in H^1(\mathbb{R}_+; Y) \times X \times H^1(\mathbb{R}_+; U) \mid A_{-1}x_0 + Bu(0) \in X, \; y(0) = \mathcal{C}x_0 + Du(0) \}. \]
The resulting operator family will be associated to a time-varying Lax-Phillips evolution family, which uniquely determines a time-varying well-posed system.

Proposition 3.7 in [1] is the key to the approach:

**Theorem II.3.** Let \( T, \Phi, \Psi \) and \( \mathcal{F} \) be two-parameter families of linear operators defined on some \( \Delta_J \), mapping as in [III] and having the causality properties (II.4). These families form a well-posed system if and only if the (Lax-Phillips) family
\[ \mathcal{S}(t, \tau) := \begin{bmatrix} S_{\tau}^{-} & S_{\tau}^{-} & \mathcal{F}(t, \tau) & S_{\tau}^{-} \\ 0 & T(t, \tau) \Phi(t, \tau) S_{\tau}^{-} \end{bmatrix}, \quad t \geq 0, \]
defined for \( (t, \tau) \in \Delta_J \), is an evolution family on \( \mathcal{H} \).

See [1] §3 for more details on the connection between Lax-Phillips evolution families and well-posed systems.

The resolvent set \( \rho(A) \) of the generator \( A \) of a contraction semigroup contains \( 1 \), by the Lumer-Phillips theorem, so we may equip \( \text{dom}(A) \) with the norm \( \|x\|_1 := \|(I - A)x\|_X \) to make it a Hilbert space which is densely and continuously embedded in \( X \); this space is commonly denoted by \( X_1 \). Moreover, we define the extrapolation space \( X_{-1} \) to be the completion of \( X \) in the norm \( \|x\|_{-1} := \|(I - A)^{-1}x\|_X \). With this setup, \( X_{-1} \) can be identified with the dual of \( X_1^d := \text{dom}(A^*) \) with pivot space \( X \), so that
\[ \langle x, z \rangle_{X_{-1}, X_1^d} = \langle x, z \rangle_X, \quad x \in X, \; z \in X_1^d. \] Furthermore, the unitary operator \( I - A : \text{dom}(A) \to X \) can be uniquely extended into a unitary operator \( I - A_{-1} : X \to X_{-1} \), where \( A_{-1} \) is the unique extension of \( A \) to an operator in \( \mathcal{L}(X; X_{-1}) \). Then \( A \) has the maximality property that \( \text{dom}(A) = \{ x \in X \mid A_{-1}x \in X \} \).

With this setup, well-posed systems on Hilbert spaces can always be written in the form (II.1), since they are compatible by [11] Thm 5.1.12. The operator \( \mathcal{C} \in \mathcal{L}(Z; Y) \) is called a compatible extension of the observation operator \( C \) to the solution space
\[ Z := \text{dom}(A) + (\alpha - A_{-1})^{-1}BU, \] for some \( \alpha \) in the resolvent set \( \rho(A) \), where the particular choice of \( \alpha \) does not matter. By [11] Lemma 4.3.12, \( Z \) is a Hilbert space with
\[ \|x\|_Z^2 = \inf_{Ax + Bu \in X} \|Ax + Bu\|_X^2 + \|x\|_X^2 + \|u\|_U^2, \] and \( (\alpha - A_{-1})^{-1}B \in \mathcal{L}(U; Z) \). We have \( \text{dom}(A) \subset Z \subset X \) with continuous embeddings, and \( Z \subset X \) is dense, but in general \( \text{dom}(A) \subset Z \) is not dense, so that \( \mathcal{C} \) is in general not uniquely determined by \( C \). However, \( \mathcal{C} \) is uniquely determined by the system and \( D \). See [11] §5.1 for more details.

By [3] Prop. 5.2 or [11] Thm 11.1.5, a time-invariant, well-posed system \( \Sigma_i \) is passive if and only if
\[ 2\text{Re} \langle A_{-1}x + Bu, u \rangle \leq \|u\|^2 - \|\mathcal{C}x + Du\|^2 \] for all \( x \in X \) and \( u \in U \) such that \( A_{-1}x + Bu \in X \). We say that \( \Sigma_i \) is energy preserving if all continuous trajectories satisfy (II.1) with equality, and this is equivalent to (II.12) holding with equality.

**III. TIME-VARYING PERTURBATION OF MAXIMAL DISSIPATIVE OPERATORS**

The presentation in this section follows [1], with some ingredients added from [2]. We introduce two functions \( P, G : J \to \mathcal{L}(X) \) which we use to perturb a maximal dissipative operator on \( X \). Throughout the paper, these functions have the following properties, for all \( t \in J \) and \( z \in X \):
\[ P(t) = P(t)^\star \geq 0, \quad P(t) \text{ has an inverse in } \mathcal{L}(X), \]
\[ P(\cdot)z, P(\cdot)^{-1}z \in C^1(J; X) \text{ for all } z \in X, \]
\[ G(\cdot)z \in C(J; X) \text{ for all } z \in X. \]
From these assumptions and the uniform boundedness principle, see [14] Thm 2.6 or [15] Thm 1.1.11, it follows that \( P(\cdot), P(\cdot)^{-1}, \overset{\cdot}{P}(\cdot), \) and \( G(\cdot) \) are all uniformly bounded on compact subintervals of \( J \). Moreover,
\[ \frac{d}{dt} P(t)^{-1}z = -P(t)^{-1}\overset{\cdot}{P}(t)P(t)^{-1}z, \quad t \in J. \]

**Theorem III.1.** In addition to (II.1), let \( G(\cdot)z \in C^1(J; X) \) for all \( z \in X \). Then
\[ A(t) := P(t)^{-1}A + G(t), \quad t \in J, \]
\[ \text{dom}(A(t)) := \text{dom}(A), \]
generates an evolution family \( \mathbb{T}_t \) on \( X \) with time interval \( J \), so that for all \( (t, \tau) \in \Delta_J \) and \( x_{\tau} \in \text{dom}(A) \), \( \mathbb{T}_t(t, \tau)x_{\tau} \in \text{dom}(A) \) and \( x(t) := \mathbb{T}_t(t, \tau)x_{\tau} \) solves the Cauchy problem
\[
\dot{x}(t) = A_t(t)x(t), \quad t \in J_{\tau}, \quad x(\tau) = x_{\tau}.
\] (III.4)

The restriction of \( \mathbb{T}_t \) to a compact \( \Delta_{a,b} \) has an exponential bound which depends only on the maximal values of \( \|P(t)^{-1}\| \), \( \|P(t)\| \) and \( \|G(t)\| \) on \([a,b]\).

For all \( x_0 \in \text{dom}(A) \), the function
\[
(t, \tau) \mapsto A_t(t)x(t)_0,
\] (III.5)

is in \( C(\Delta_J; X) \).

For all \( t \in J \) with \( t > \inf J \) and \( x_0 \in \text{dom}(A_{t}) \), the function \( \tau \mapsto \mathbb{T}_t(t, \tau)x_0 \) is continuously differentiable in \( X \), on \( \{ \tau \in J \mid \tau \leq t \} \), and
\[
\frac{\partial}{\partial \tau} \mathbb{T}_t(t, \tau)x_0 = -\mathbb{T}_t(t, \tau)A_t(\tau)x_0.
\] (III.6)

In general the exponential bounds of \( \mathbb{T}_t \) depend on the compact subinterval \([a,b] \subset J \), but if \( P(\cdot)^{-1}, P(\cdot) \) and \( G(\cdot) \) are uniformly bounded on all of \( J \), then \( \mathbb{T}_t \) is globally exponentially bounded, rather than only locally.

Proof. We temporarily restrict \( t \) and \( \tau \) to a compact subinterval \([a,b] \subset J \) and throughout we assume that \( t > a \). By [1 p. 271], \( P(t)^{-1}A \) generates a \( C_{0} \)-semigroup on \( X \) for every fixed \( t \), and the family \( t \mapsto P(t)^{-1}A \) is a stable family of semigroup generators in the sense of [16 Def. 5.2.1], with stability constants that depend only on the maximal values of \( \|P(t)\| \) and \( \|P(t)^{-1}\| \) on \([a,b]\). Since \( \|G(t)\| \leq K \) for some \( K \) independent of \( t \), it follows from [16 Thm 5.2.3] that \( A_t(t), t \in [a,b] \), is also a stable family of semigroup generators, whose stability bound \( (M, \omega) \) further depends on the bound \( K \) of \( \|G(\cdot)\| \) on \([a,b]\). By [16 Thm 5.4.8], the evolution family generated by \( A_t(\cdot) \) on \([a,b]\) has the same exponential bound \((M, \omega)\), and it satisfies all the assertions with \( J \) replaced by \([a,b]\) and \([III.5]\) replaced by
\[
(t, \tau) \mapsto \mathbb{T}_t(t, \tau)x_{\tau} \in C(\Delta_{[a,b]}; X_1).
\]
From this follows, however, that \( (t, \tau) \mapsto AT(t, \tau)x_{\tau} \in C(\Delta_{[a,b]}; X) \), and by the uniform boundedness of \( P(\cdot)^{-1} \) on \([a,b]\), \( [III.5] \) holds with \( J \) replaced by \([a,b]\).

Every fixed pair \( (t, \tau) \in \Delta_J \) is contained in some \( \Delta_{[a,b]} \) with \([a,b]\) compact. Therefore, the family \( \mathbb{T}_t(t, \tau) \) defined for every \( (t, \tau) \in \Delta_J \) as the evolution family generated by \( A_t(\cdot) \) with the time interval \([t, \tau]\), has properties 1)-3) and a) in Def. [II.1].

Every point \((t_0, \tau_0) \in \Delta_J \), where we may want to verify continuity in condition 4) or \([III.5]\) is also contained in some compact \( \Delta_{[a,b]} \). This proves in particular that \( \mathbb{T}_t(t, \cdot)x_0 \in C^1(J; X) \), and that the latter satisfies \([III.6]\) for all \( \tau \in J \) with \( \tau \leq t \).

In order to drop the extra assumption that \( G \) is strongly in \( C^1 \), we define the \( \mathcal{L}(X) \)-valued averaged function \( G_n \) by
\[
G_n(t)z := n \int_{t}^{t+1/n} G(s)z \, ds, \quad t \in J, \quad z \in X,
\] (III.7)
where we extend \( G(t) := G(b), t > b \), if \( J \) has a finite right endpoint \( b \); then \( G_n(z) \in C^1(J; X) \) for all \( z \in X \) and \( \|G(t)\| \leq K \) for \( t \) in a compact interval \([a, b + 1/n] \) implies that \( \|G_n(z)\| \leq K \) for \( t \in [a, b] \).

The dual \( X^*_t \) of \( dom(A^*P(t)^{-1}) \) with pivot space \( X \) can be identified with the extrapolation space of \( P(t)^{-1}A \) in Thm [III.1]. Moreover, the operators \( P(t)^{-1} \) extend to locally uniformly bounded isomorphisms \( P(t)^{-1} : X_{1} \rightarrow X_{t} \), with locally uniformly bounded inverses by [II Prop. 4.2(a)], so that we may identify \( X^*_t \) with \( X_{1} \). In practice, however, it is often easiest to use the time-varying norm
\[
\|x\|_{1} = \| (I - P(t)^{-1}A_{1})^{-1}x \|_{X}
\]
on \( X_{-1} \), where \( A_{-1} \) is the extension of \( A \) to an operator in \( \mathcal{L}(X; X_{-1}) \). Then [II.9] holds with \( X_{1} \) replaced by \( X_{1}^d(t) := \text{dom}(A^*P(t)^{-1}) \).

By Thm [III.1] the family
\[
A_n(t) := P(t)^{-1}A + G_n(t),
\] (III.8)
\[
\text{dom}(A_n(t)) := \text{dom}(A), \quad t \in J,
\]
generates an evolution family \( \mathbb{T}_n \) on \( X \) with time interval \( J \), whose restrictions to compact intervals \([a,b] \subset J \) have exponential bounds which are independent of \( n \). With the setup in the preceding paragraph, \( A_t(t) \) and \( A_n(t) \) have unique extensions to operators in \( \mathcal{L}(X; X_{-1}) \), and we denote these extensions by \( A_{-1,n}(t) \) and \( A_{-1,n}(t) \), observing that
\[
A_{-1,n}(t) = P(t)^{-1}A_{-1} + G(t), \quad t \in J,
\] (III.9)
and analogous for \( A_{-1,n}(t) \).

Theorem III.2. For all \((t, \tau) \in \Delta_J \) and \( z \in X \), the limit
\[
\mathbb{T}_t(t, \tau)z := \lim_{n \to \infty} \mathbb{T}_n(t, \tau)z
\] (III.10)
exists, with uniform convergence on \( \Delta_{[a,b]} \) for compact \([a,b] \subset J \), and \( \mathbb{T}_t(t, \tau)z \) is the unique locally exponentially bounded evolution family on \( X \) with time interval \( J \), which satisfies
\[
\mathbb{T}_t(t, \tau)z = U(t, \tau)z + \int_{\tau}^{t} U(t, s)G(s)T_{t}(s, \tau)z \, ds
\] (III.11)
for all \( z \in X \) and \((t, \tau) \in \Delta_J \), where \( U \) is the locally exponentially bounded evolution family generated by \( P(\cdot)^{-1}A \).

If \( G(z) \in C^1([a,b]; X) \) for all \( z \in X \), then \( \mathbb{T}_t(t, \tau)z \) equals the evolution family in Thm [III.7].

For every \( \tau \in J \) with \( \tau \leq \text{sup} J \) and \( x_{\tau} \in X \),
\[
x(t) := \mathbb{T}_t(t, \tau)x_{\tau}, \quad t \in J_{\tau},
\]
is a solution in \( C(J_{\tau}; X) \) of the equation
\[
x(t) - x_{\tau} = \int_{\tau}^{t} A_{-1,n}(s)x(s) \, ds, \quad (t, \tau) \in \Delta_J,
\] (III.12)
where the integral is computed in \( X_{-1} \).

A function \( z \in C(J_{\tau}; X) \) solves (III.12) if and only if it is in \( C(J_{\tau}; X) \cap C^1(J_{\tau}; X_{-1}) \) and solves the following Cauchy problem in \( X_{-1} \):
\[
\dot{x}(t) = A_{-1,n}(t)x(t), \quad t \in J_{\tau}, \quad x(\tau) = x_{\tau}.
\] (III.13)

Uniqueness in (III.11) holds in the following stronger sense: Assume that \( S(t, \tau) \) is a two-parameter family of operators in
\(\mathcal{L}(X)\), such that \(S(s,\cdot)z\) is weakly continuous for all \(z \in X\), and (III.11) holds with \(S\) in place of \(T_1\) with weak integrals, for all \(x_0 \in X\) and \((t, \tau) \in \Delta_J\). Then \(S = T_1\).

Surprisingly, proving uniqueness of the solutions of (III.12) and (III.13) turned out tricky. The proof of [2] Thm 3.9] uses properties of \(C_0\)-semigroups which may have no counterpart for evolution families in general. We will return to this later, in a remark immediately after Thm (IV.1).

**Proof.** We again fix a compact subinterval \([a, b] \subset J\).

**Step 1:** Constructing \(T_1\) by applying a Trotter-Kato theorem to the Howland evolution semigroup \(T_0\). With the supremum norm, \(C([a, b]; X)\) is a Banach space. For \(\sigma \geq 0\) and \(t \in [a, b]\), define

\[
\sigma \mapsto (E^f_\sigma(t)) := \begin{cases} 
T_n(t, t - \sigma) f(t - \sigma), & t - \sigma \in [a, b], \\
T_n(t, a) f(a), & \text{otherwise.}
\end{cases}
\]

By showing that the function \((t, \sigma) \mapsto (E^f_\sigma(t))\) is in \(C([a, b] \times \mathbb{R}_+; X)\), hence uniformly continuous on \([a, b] \times [0, 1]\), one can show that \(\sigma \mapsto E^f_\sigma, \sigma \in \mathbb{R}_+, \) is a \(C_0\)-semigroup on \(C([a, b]; X)\), which is called the (Howland) evolution semigroup \([17]\) associated to \(T_n\). An evolution family is uniquely determined by its Howland semigroup, because

\[
T_n(t, \tau) f(\tau) = (E^{t - \tau}_\sigma f)(\tau), \quad (t, \tau) \in \Delta_{[a, b]}, \quad (III.14)
\]

for all \(f \in C([a, b]; X)\), and for all \(z \in X\) there exists some continuous \(f\) with \(f(\tau) = z\). Moreover, \(\|E^f_\sigma\| \leq Me^{\omega \sigma}\) if \((M, \omega)\) is an exponential bound for \(T_n\) on \([a, b]\).

The argument in the proof of [13] Thm 3.12, see also [2] Prop. 3.4], can be slightly adapted to establish that the generator of \(E^f_\sigma\) is the unique closure \(G_0\) (as an unbounded operator on \(C([a, b]; X)\)) of

\[
(G_0 f)(t) := A_n(t) f(t) - f(t'), \quad t \in [a, b],
\]

\[
\text{dom}(G_0) := \{ f \in C^1([a, b]; X) \mid \forall t \in [a, b] : (III.15)
\]

\[
f(t) \in \text{dom}(A), \quad A_n(t) f(t) \in C([a, b]; X)\}.
\]

In particular, the denseness in \(C([a, b]; X)\) of the linear span of functions \(t \mapsto \alpha(t) T_n(t, \tau) x_\tau \) for \(t > \tau\) and \(t \mapsto 0\) for \(t \leq \tau\), where \(\alpha \in C^1(\mathbb{R})\) with compact support contained in \((\tau, \infty)\), follows easily from the denseness of this span in \(C_0(\mathbb{R}; X)\), the space of continuous \(X\)-valued functions tending to zero at \(\pm \infty\). Due to the continuity and the uniform boundedness of \(P(\cdot), P(\cdot)^{-1}\) and \(G_n(\cdot)\) on \([a, b]\), the condition \(A_n(\cdot) f(\cdot) \in C([a, b]; X)\) is equivalent to \(Af(\cdot) \in C([a, b]; X)\), and hence the core domain \(G_0\) is independent of \(n\).

As in the proof of [2] Prop. 3.7], the uniform boundedness of \(G\) on \([a, b]\) implies that the pointwise multiplication operators \(M(\cdot)\) and \(M_n(\cdot)\) are bounded on \(C([a, b]; X)\), and that \(M_n f \to M(\cdot) f\) for all \(f \in C([a, b]; X)\), so that \(G_n f \to G f\) in \(C([a, b]; X)\) for all \(f\) in the core domain \((G_0, n)\), where

\[
G := G_n + M(\cdot) - M_n(\cdot).
\]

Proceeding as in step 2 of the proof of [2] Thm 3.8], we get that \(G\) generates a strongly continuous semigroup \(E^f\) on \(C(X; [a, b])\) and that \(\|E^{f_n}_\sigma f - E^{f}_\sigma f\|_{t \to \infty} \to 0\) as \(n \to \infty\) for all \(f \in C([a, b]; X)\) and \(\sigma \geq 0\), where \(\|\cdot\|_\infty\) is the maximum norm on \([a, b]\), uniformly for \(\sigma\) restricted to compact intervals.

If \(G(\cdot)\) is strongly continuously differentiable and we denote the evolution family in Thm (III.1) by \(T_1\), then the generator of the Howland semigroup of \(T_1\) coincides with \(G\) on the core \((G_0, n)\). Then \(G \mapsto E^f\) is the Howland semigroup of both \(T_1\) and \(T_1\), and so \(T_1 = T_1\) on \(\Delta_{[a, b]}\).

Now the proof of [2] Lemma 3.6] gives that \(T_1(t, \tau) z = \lim_{n \to \infty} \eta_n(t, \tau) z\) exists for all \(z \in X\) and \((t, \tau) \in \Delta_{[a, b]}\), with uniform convergence over \((t, \tau) \in \Delta_{[a, b]}\) since here \(t - \tau \in [0, b - a]\). Then \(T_1\) inherits properties 2)–4) in Def. (III.1) with \([a, b]\) instead of \(J\), from \(T_1\). Moreover,

\[
||T_1(t, \tau) z|| = \lim_{n \to \infty} ||T_n(t, \tau) z|| \leq M e^{\omega(t - \tau)} ||z||,
\]

so that \(T_1(t, \tau)\) is bounded for all \(t \in [a, b]\). This proves that \(T_1\) is an exponentially bounded evolution family on \(X\) with time interval \([a, b]\). Moreover, \(T_1\) is seen to be an evolution family on \(X\) with time interval \([a, b]\), corresponding to the locally exponentially bounded evolution families \(U\) and \(T_1\), respectively. By [12] Cor. III.1.7],

\[
E^{t - \tau}_U f = E^{t - \tau}_U f + \int_0^{t - \tau} E^{t - \tau - s}_U M(\cdot) E^{t - s}_U f \, ds \quad (III.16)
\]

holds in \(C([a, b]; X)\) for all \(t - \tau \geq 0\) and \(f \in C([a, b]; X)\). Letting \(z \in X\) be arbitrary, picking some continuous \(f\) with \(f(s) = z\), and evaluating (III.16) in \(t\), we get the following from (III.14), where \(\delta_1 \in C([a, b]; X)\) is point evaluation at \(t \in [a, b]\):

\[
T_1(t, \tau) z - U(t, \tau) z = \delta_1 \int_0^t E^{t - \tau}_U M(\cdot) E^{t - \tau}_U f \, dr
\]

\[
\int_0^t U(t, \tau) \delta_1 (M(\cdot) E^{t - \tau}_U f) \, dr = \int_0^t U(t, \tau) \delta_1 (M(\cdot) E^{t - \tau}_U f) \, dr \quad (III.17)
\]

Thus \(T_1\) satisfies (III.11) for all \((t, \tau) \in \Delta_{[a, b]}\), and since \([a, b] \subset J\) is arbitrary, (III.11) holds for all \((t, \tau) \in \Delta_J\). Uniqueness follows by applying Grönwall’s theorem to \(\phi(t) := ||S(t, \tau) z - T_1(t, \tau) z||\), using that \((U, \cdot, \cdot)\) and \(G\) are uniformly bounded on every \([\tau, t]\).

**Step 3:** \(x = T_1(t, \tau) x\) solves (III.12). Since \(A_n(\cdot)\) generates \(T_1\) with time interval \(J\), (III.4) holds with \(A_n(\cdot)\) replaced by \(A_n(\cdot)\) and \(x_\tau \in \text{dom}(A_n(\cdot))\). Integrating, we get

\[
T_n(t, \tau) x_\tau - x_\tau = \int_0^t A_n(s) T_n(s, \tau) x_\tau \, ds \quad (III.18)
\]

as an equality in \(X\), and hence in \(X_{-1}\). We can replace \(A_n(s)\) by its extension \(A_{-1,n}(s)\) and compute the integral in \(X_{-1}\) instead of in \(X\).

For all \(z \in X\) and \(s \in [\tau, t]\),

\[
||A_{-1,n}(s) z||_{-1} \leq \||I - P(s)^{-1} A^{-1} - I|| \, z|| + \||I - P(s)^{-1} A^{-1} P(s)^{-1} G(s) z|| \leq L ||z||,
\]
by \([I] (2.7)\) and the uniform boundedness of \(G(\cdot)\) on \([a, b]\). Local uniform boundedness of \(A_{-1, l}(s)\) as an operator in \(L(X; X_{-1})\) follows, and since \(G_n\) has the same uniform bound as \(G\), also \(\|A_{-1, n}(s)\|_{L(X; X_{-1})} \leq L\) on compact subintervals of \(J\). By a similar argument, for \(f \in C([\tau, t]; X)\) and \(s \in [\tau, t]\),
\[
\|A_{-1, n}(s) f(s) - A_{-1, l}(s) f(s)\|_{-1} \leq N \|G_n(s) f(s) - G(s) f(s)\|,
\]
and by \([II] (3.21)\), for all \(f \in C([a, b]; X)\):
\[
\lim_{n \to \infty} \sup_{s \in [a, b]} \|G_n(s) f(s) - G(s) f(s)\| = 0. \tag{III.19}
\]
Gathering the above, we get for \(x_\tau \in X\) and \(s \in [\tau, t]\), that
\[
\|A_{-1, n}(s) T_n(s, \tau) x_\tau - A_{-1, l}(s) T_l(s, \tau) x_\tau\|_{-1} \leq L \cdot \|T_n(s, \tau) x_\tau - T_l(s, \tau) x_\tau\| + \|A_{-1, n}(s) - A_{-1, l}(s)\| T_l(s, \tau) x_\tau\| \to 0,
\]
uniformly in \(s \in [\tau, t]\) as \(n \to \infty\). Hence, letting \(n \to \infty\) in (III.18), we get (III.12) for \(x_\tau \in \text{dom} (A)\). From
\[
\left\| \int_\tau^t A_{-1, l}(s) T_l(s, \tau) x_\tau\, ds \right\|_{-1} \leq (t - \tau) L M e^{\omega(t - \tau)} \|x_\tau\|
\]
it follows that we can extend (III.12) by density to all of \(X\).

**Step 4: The Cauchy problem in \(X_{-1}\):** Now let \(z \in C([\tau, t]; X)\) be any solution of (III.12). Then \(z(\tau) = x_\tau\) and it is clear that \(z(\cdot)\) and its derivative \(A_{-1, l}(\cdot) z(\cdot)\) are both in \(C(J_\tau; X_{-1}\)), and that \(z(\cdot)\) is a solution of the Cauchy problem (III.13). Conversely, if \(z \in C(J_\tau; X) \cap C(J_{-1}; X_{-1}\)) solves (III.13), then, by integration, \(z\) also solves (III.12). \(\square\)

The following consequences of the above theorems are of particular interest when developing the theory for multiplicative perturbation from the right, the case corresponding to \([I]\):

**Corollary III.3.** The family
\[
\hat{A}_n(t) := P(t) A + P(t) G_n(t) P(t)^{-1}, \quad t \in J,
\]
generates an evolution family \(\hat{T}_n\) on \(X\) with time interval \(J\).

For all \((t, \tau) \in \Delta_J\) and \(z \in X\), the strong limit
\[
\hat{T}_l(t, \tau) z := \lim_{n \to \infty} \hat{T}_n(t, \tau) z, \quad z \in X, \tag{III.20}
\]
exists, with uniform convergence on \(\triangle_{[a, b]}\) for compact intervals \([a, b] \subset J\), and
\[
V(t, \tau) z := P(t)^{-1} \hat{T}_l(t, \tau) P(\tau) z, \quad z \in X, \tag{III.21}
\]
is a locally exponentially bounded evolution family on \(X\) with time interval \(J\).

If \(G(\cdot) z \in C^1([a, b]; X)\) for all \(z \in X\), then \(V\) is generated by \(A P(t) G(t) P(t)^{-1}\) with domain \(P(t)^{-1}\text{dom} (A)\), \(t \in J\).

The first two claims follow from the uniform boundedness of \(P(\cdot)\) and its inverse on compact subintervals of \(J\), together with Thms \([III.1]\) and \([II]\). By the latter, if \(G(\cdot)\) is strongly continuously differentiable, then the evolution family \((t, \tau) \mapsto P(\cdot) V(t, \tau) P(\cdot)^{-1}\) is generated by \(P(\cdot) A + P(\cdot) G(\cdot) P(\cdot)^{-1}\). Then the last assertion follows from \([I]\) Rem. 2.6.

Next we need the extrapolation space of \(A P(t)\). This space can be identified with \(X_{-1}\), and \(A_{-1, r}(t) := A_{-1} P(t) + G(t)\) is the unique extension to \(L(X; X_{-1})\) of
\[
A_r(t) := A P(t) + G(t), \quad \text{dom} (A_r(t)) := P(t)^{-1}\text{dom} (A)\; \tag{III.22}
\]
see the paragraph before \([I]\) Def. 2.5.

**Theorem III.4.** With \(V\) defined in (III.21), there exists a unique evolution family \(T_r\) with time interval \(J\), such that
\[
T_r(t, \tau) x_\tau = V(t, \tau) x_\tau \quad + \int_\tau^t V(t, s) P(s)^{-1} \hat{P}(s) T_r(s, \tau) x_\tau\, ds \tag{III.23}
\]
for all \(x_\tau \in X\) and \((t, \tau) \in \Delta_J\). This \(T_r\) is also the unique solution of
\[
T_r(t, \tau) x_\tau = V(t, \tau) x_\tau \quad + \int_\tau^t T_r(s, \tau) P(s)^{-1} \hat{P}(s) V(s, \tau) x_\tau\, ds \tag{III.24}
\]
For every \(\tau \in J\) with \(\tau < \text{sup} J\) and \(x_\tau \in X\),
\[
x(t) := T_r(t, \tau) x_\tau, \quad t \in J, \tag{III.25}
\]
is in \(C^1(J_\tau, X_{-1})\) and it solves the Cauchy problem (III.13) with \(A_{-1, r}\) replaced by \(A_{-1, l}\) in \(X_{-1}\).

Uniqueness in (III.23) and (III.24) holds in the same sense as uniqueness in (III.11).

**Proof.** Step 1: Assertion one. By temporarily restricting to compact subintervals \([a, b] \subset J\). On this interval \(G(\cdot)\), \(P(\cdot)\), \(P(\cdot)^{-1}\) and \(\hat{P}(\cdot)\) are uniformly bounded and the family
\[
\hat{A}_n(t) := A P(t) + G_n(t) - P(t)^{-1} \hat{P}(t),
\]
\[
\text{dom} (\hat{A}_n(t)) := P(t)^{-1}\text{dom} (A)\;
\]
generates an evolution family \(V_n\) with time interval \([a, b]\) by the proof sketch for Cor. \([III.3]\). For \(t \in [a, b]\),
\[
\hat{A}_n(t) := P(t) A^* + G_n(t)^*, \quad \text{dom} (\hat{A}_n(t)) = \text{dom} (A^*),
\]
generates a locally exponentially bounded backward evolution family \(S_n\) with time interval \([a, b]\), see \([I]\) Def. 2.5 and the discussion in step three of the proof of \([II]\) Prop. 5.1, by the backward version of Thm \([III.1]\). We will prove that \(T_r(t, \tau) z = \lim_{n \to \infty} S_n(t, \tau)^* z\) for all \(z \in X\).

First we calculate, for \(w_n \in \text{dom} (\hat{A}_n)\),
\[
\frac{\partial}{\partial s} \langle S_n(t, s)^* V_n(s, \tau) w_n, z \rangle =
\]
\[
\langle \hat{A}_n(s) V_n(s, \tau) w_n, S_n(t, s) z \rangle
\]
\[
- \langle V_n(s, \tau) w_n, \hat{A}_n(s) S_n(t, s) z \rangle
\]
\[
- \langle P(s)^{-1} \hat{P}(s) V_n(s, \tau) w_n, S_n(t, s) z \rangle.
\]
Integrating this from $\tau$ to $t$ results in
\[
\langle S_n(t, \tau)^* w_n, z \rangle = \langle \nabla_n(t, \tau) w_n, z \rangle
+ \int_{\tau}^{t} \left\langle P(s)^{-1} \dot{P}(s) \nabla_n(s, \tau) w_n, S_n(t, \tau) z \right\rangle \, ds.
\tag{III.26}
\]
Assuming that $w_n \to w$ in $X,$ we get $\nabla_n(s, \tau) w_n \to \nabla(s, \tau) w$ (since $\nabla_n$ have a uniform exponential bound on compact intervals which is independent of $n$) for the first assertion in Thm III.2 and $S_n(t, \tau) z \to S(t, \tau) z$ for some $S(t, \tau) z,$ both uniformly on $s \in [\tau, t]$ by Cor. III.3. By the uniform boundedness of $P(s)^{-1} P(s)$ on $[\tau, t],$ and the fact that $S_n$ and $\nabla$ have some common exponential bound independent of $n$ and $s \in [\tau, t],$ we then get uniform convergence of the integrand, so that (III.26) tends to
\[
\langle S(t, \tau)^* w, z \rangle = \langle \nabla(t, \tau) w, z \rangle
+ \int_{\tau}^{t} \left\langle S(t, \tau)^* P(s)^{-1} \dot{P}(s) \nabla(s, \tau) w, z \right\rangle \, ds
\]
as $n \to \infty,$ for $w \in X$ and $z \in \text{dom}(A^*),$ and by denseness also for all $z \in X.$ From the uniqueness of solution of (II.24), we get $S(t, \tau)^* = T_t(t, \tau).$

Step 3: Assertion two. Now we establish that $T_t(t, \tau)x_0$ solves the Cauchy problem (II.13), with $l$ replaced by $r.$ We have $\frac{\partial}{\partial \tau} S_n(s, \tau) z_0 = S_n(s, \tau) A_0^t(s) z_0$ for all $z_0 \in \text{dom}(A^*),$ and $\tau \in [a, b].$ Integrating from $\tau$ to $t,$ we get
\[
S_n(t, \tau) z_0 = \int_{\tau}^{t} S_n(s, \tau) A_0^t(s) z_0 \, ds,
\]
and for an arbitrary $x_\tau \in X,$ we have
\[
\langle S_n(t, \tau)^* x_\tau, z_0 \rangle - \langle x_\tau, z_0 \rangle = \int_{\tau}^{t} \langle \langle A_0^t(s) + G_n(s) \rangle S_n(s, \tau)^* x_\tau, z_0 \rangle_{X, X_{-1}} \, ds.
\]
Letting $n \to \infty,$ strong convergence of $G_n$ to $G$ in $C([a, b]; X)$ gives
\[
T_t(t, \tau)x_\tau = \int_{\tau}^{t} A_0^t(s) T_t(s, \tau)x_\tau \, ds
\]
in $X_{-1}.$ Proceeding as in step 3 of the proof of Thm III.2 we get assertion three.

We can say more about $T_t$ if $P(\cdot)$ and $G(\cdot)$ are smoother:

**Proposition III.5.** Assume that $P(\cdot) z \in C^2(J; X)$ and $G(\cdot)z \in C^1(J; X)$ for all $z \in X.$

The family $A_0(\cdot)$ of Thm III.2 generates $T_t$ in Thm III.2, i.e.,
\[
T_r(t, \tau) \text{ dom}(A_0(\tau)) \subset \text{dom}(A_0(t))
\tag{III.27}
\]
for $(t, \tau) \in \Delta_J,$ and $x$ in $\text{dom}(A_0(\cdot))$ is a solution of $C^2(J, X)$ of the Cauchy problem in $X,$ instead of only in $X_{-1}.$ The map
\[
\Delta_J \ni (t, \tau) \mapsto AP(t) T_t(t, \tau) (I - AP(\tau))^{-1} z
\]
is continuous in $X,$ for all $z \in X.$

**Proof.** Due to Thm III.1, the family
\[
A_2(t) := P(t) A + (P(t) G(t) P(t)^{-1} + \dot{P}(t) P(t)^{-1})
\]
with dom $(A_2(t)) = \text{dom}(A),$ generates an evolution family $S$ such that $(t, \tau) \mapsto A_2(t) S(t, \tau)x_\tau$ is in $C(\Delta_J; X)$ for all $x_\tau \in \text{dom}(A),$ since $P(t) G(t) P(t)^{-1} + \dot{P}(t) P(t)^{-1}$ is strongly continuously differentiable. Then $A_2(t)$ generates the evolution family $(t, \tau) \mapsto P(t)^{-1} S(t, \tau) P(\tau)$ by the proof sketch of Cor. III.3. The family $P(t) A + P(t) G(t) P(t)^{-1}$ also generates a locally exponentially bounded evolution family $T_t,$ and by Cor. III.3 $P(t)^{-1} T_t(t, \tau) P(\tau) = \nabla(t, \tau).$ By Thm III.1 for $z \in \text{dom}(A), S(t, \tau) z \in \text{dom}(A)$ and
\[
\frac{\partial}{\partial s} T_t(t, s) S(t, \tau) z = T_t(t, s) P(s) P(s)^{-1} S(t, \tau) z.
\]

Proceeding as in the proof of [Prop.2.8.4]], we get $P(t)^{-1} S(t, \tau) P(\tau) = T_r(t, \tau)$ and the claimed continuity. $\square$

**IV. Well-posedness of $\Sigma$ and $\Sigma_r$**

We use the Lax-Phillips evolution families associated to (1.3) and (1.4) in order to prove the well-posedness of these time-varying linear systems and their passivity property.

**A. Multiplicative perturbation from the left**

Let $[\begin{array}{cc} A & B \\ C & D \end{array}]$ be a time-invariant, passive well-posed system, with Lax-Phillips semigroup $T_t$ on $H,$ generated by the maximal dissipative operator $A$ in (II.7), By a classical trajectory of the time-varying system
\[
\begin{bmatrix}
P(t) \dot{x}(t) \\
y(t)
\end{bmatrix} = \begin{bmatrix}
A-1 + P(t) G(t) & B \\
C & D
\end{bmatrix} \begin{bmatrix}
x(t) \\
u(t)
\end{bmatrix}
\tag{IV.1}
\]
on $J_r$, $\tau \in J$ with $\tau < \text{sup}(J),$ we mean a triple $(u, x, y) \in C(J_r; U) \times C^1(J_r; X) \times C(J_r; Y),$ such that (IV.1) holds for all $t \in J_r.$

For $t \in J,$ define the following operators in $\mathcal{L}(H):
\[
\Psi(t) := \begin{bmatrix}
I & 0 \\
0 & 0
\end{bmatrix}, \quad \text{and} \quad \Theta(t) := \begin{bmatrix}
0 & 0 \\
0 & G(t)
\end{bmatrix},
\tag{IV.2}
\]
so that $\Psi(t) := \Psi(t)^{-1} \Psi + \Theta(t)$ equals
\[
\begin{bmatrix}
y' \\
x
\end{bmatrix} = \begin{bmatrix}
\begin{bmatrix}
P(t)^{-1} \left( A_1 x_0 + Bu(0) \right) + G(t)x_0
\end{bmatrix} \\
u'
\end{bmatrix},
\tag{IV.2}
\]
with dom $(\Psi(t)) = \text{dom}(A), t \in J.$

Thm III.2 implies that the family $\Psi(t)$ generates an evolution family $T_t$ on $H$ with time interval $J$ if $G(\cdot)$ is strongly continuously differentiable, and we will prove that $T_t$ is the Lax-Phillips evolution family of a (unique, time-varying) well-posed system $\Sigma,$ whose classical trajectories with smooth data are determined by (1.3).

**Theorem IV.1.** Let $\tau \in J$ be such that $\tau < \text{sup}(J).$ There is a well-posed system $\Sigma_t = [\begin{array}{c} x(t) \\ y(t) \end{array}]$ with Lax-Phillips evolution family $T_t$ and time interval $J,$ such that the evolution family $T_t$ of $\Sigma_t$ has the properties asserted in Thm III.2 and moreover:

1. Let $(u, x, y)$ be a classical trajectory of (IV.1) on $J_r.$ Then $x \in C(J_r; Z), X$ where $Z$ is the solution space in (II.10). Moreover, if $(x(\tau), u)$ is in
\[
V(\tau) := \left\{ \begin{bmatrix}
x_\tau \\
u
\end{bmatrix} \in \mathbb{H}^{-1}(J; U) : A_1 x_\tau + Bu(\tau) \in X \right\},
\tag{IV.10}
\]

then \((u, x, y)\) is a trajectory of \(\Sigma_t\) on \(J_r\) with \(x(\tau) = x_r: \)
\[
 x(t) = T_{\tau}(t, \tau)x_{\tau} + \Phi_{\tau}(t, \tau)u,
\]
\[
P_{[\tau, t]}y = \Psi_{\tau}(t, \tau)x_{\tau} + F_{\tau}(t, \tau)u, \quad t \in J_r.
\]
(IV.3)

2) For \(x, u \in X \) and \(u \in L^2(J_r; X)\), the function

\[
x(t) := T_{\tau}(t, \tau)x_{\tau} + \Phi_{\tau}(t, \tau)u, \quad t \in J_r,
\]

is in \(H^{1}_{loc}(J_r; X_{-1})\) and it satisfies

\[
\dot{x}(t) = A_{-1, t}x(t) + Bu(t)
\]
in \(X_{-1}\) for almost all \(t \in J_r\), where \(A_{-1, t}\) is in \((I.9)\).

3) Every trajectory \((u, x, y)\) of \(\Sigma_t\) on \(J_r\) satisfies the energy inequality \((I.5)\), for all \(t \in J_r\), and it is uniquely determined by \((x(t), u)\).

4) Every classical trajectory of \((IV.1)\) satisfies

\[
\frac{d}{dt} \langle P(t)x(t), x(t) \rangle \leq \langle \dot{P}(t)x(t), x(t) \rangle + 2\Re \langle P(t)x(t), G(t)x(t) \rangle, \quad t \in J_r.
\]
(IV.4)

If additionally \(G(\cdot)z \in C^1(J; X)\) for all \(z \in X\), then \(T_{\tau}\) has the properties asserted in Thm \((III.1)\) and further:

5) The Lax-Phillips evolution family \(T_{\tau}\) of \(\Sigma_t\) is generated by \(A_{\tau}\), \(t \in J\), in the sense of Def. \((II.1)\).

6) For every \((x, u) \in V(\tau)\) there is a (unique) classical trajectory \((u, x, y)\) of \((IV.1)\) on \(J_r\) with \(x(\tau) = x_r\). The output of this trajectory satisfies \(y \in H^{1}_{loc}(J_r; Y)\).

If \(\Sigma_t\) is energy preserving then the inequality holds with equality in \((I.5)\) and \((IV.4)\).

Hence, solutions \(x \in C^1(J_r; X)\) of \((III.12)\), or equivalently, of \((III.13)\), for which \(x_r \in \text{dom}(A)\) are unique. Indeed, they satisfy \(x \in C(J_r; \text{dom}(A)) \subset C(J_r; Z)\), see the penultimate paragraph of \((III)\) and then \((0, x_r)\) is a classical trajectory of \((IV.1)\) with \(y(t) := Cx(t), t \in J_r\), and \(G(\cdot) = 0:\)

Proof: Step 1: Power and energy balance for classical trajectories. Uniqueness of trajectories. First let \((u, x, y)\) be an arbitrary classical trajectory of \((IV.1)\): then:

\[
\begin{bmatrix}
P(t)x(t) - P(t)G(t)x(t) \\
y(t)
\end{bmatrix}
= \begin{bmatrix}
A_{-1} & B \\
C & D
\end{bmatrix}
\begin{bmatrix}
x(t) \\
u(t)
\end{bmatrix},
\]

and \((III.12)\) gives

\[
\|u(t)\|^2 - \|y(t)\|^2 \geq 2\Re \langle P(t)\dot{x}(t) - P(t)G(t)x(t), x(t) \rangle = 2\Re \langle P(t)\dot{x}(t), x(t) \rangle - 2\Re \langle G(t)x(t), P(t)x(t) \rangle,
\]

with equality if \(\Sigma_t\) is energy preserving, and observing that

\[
\frac{d}{dt} \langle P(t)x(t), x(t) \rangle = \langle \dot{P}(t)x(t), x(t) \rangle + 2\Re \langle P(t)\dot{x}(t), x(t) \rangle,
\]

we get \((IV.4)\). Integrating \((IV.4)\) from \(\tau\) to \(t \geq \tau\), we get \((I.5)\).

In every linear set of triples \((u, x, y)\) that satisfy \((I.5)\), there is at most one \((u, x, y)\) with a particular choice of

\[
x_{\tau} := x(\tau) \text{ and } u; \text{ indeed, setting } \phi(t) := \langle P(t)x(t), x(t) \rangle + \int_{\tau}^{t} \|y(s)\|^2 ds, \text{ we get from } (I.5) \text{ that}
\]

\[
\phi(t) \leq \alpha(t) + M \int_{\tau}^{t} \phi(s) ds, \quad \text{where}
\]

\[
\alpha(t) := \langle P(t)x(\tau), x(\tau) \rangle + \int_{\tau}^{t} \|u(s)\|^2 ds
\]

is non-decreasing in \(t\) and

\[
M := \sup_{x \in [\tau, t]} \left(\|P(s)^{-1/2}P(s)P(s)^{-1/2}\| + 2\|P(s)^{1/2}G(s)P(s)^{-1/2}\|\right),
\]

and Grönwall’s inequality then gives that

\[
\phi(t) \leq \alpha(t) e^{M(t-\tau)},
\]

where \(\alpha(t)\) is identically zero if \(x(\tau) = 0\) and \(u = 0:\)

Step 2: If \(G(\cdot)\) is strongly continuously differentiable. Following steps one and two of the proof of \((I)\) Thm \(4.1)\) and using Thm \((III.1)\) we get the following: \(T_{\tau}\) generates an evolution family \(T_{\tau}\) on \(H\) with time interval \(J\), and for all \((x, u) \in V(\tau)\) there exist \(\tilde{y} \in H^1([\tau, t]; Y)\) and \(\tilde{u} \in H^1([\tau, t]; U)\) such that \(\tilde{y}(0) = Cx_r + Du(\tau)\) and \(P_{[\tau, t]}\tilde{u} = u\). Then \((\tilde{y}, \tilde{x}, \tilde{s}, \tilde{u}) \in \text{dom}(A)\) and

\[
\begin{bmatrix}
y(t) \\
x(t)
\end{bmatrix} := \begin{bmatrix}
\delta_0 & 0 & 0 \\
0 & I & T_{\tau}(t, \tau) \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{y} \\
\tilde{x}_r \\
\tilde{s}, \tilde{u}
\end{bmatrix},
\]

defines a classical trajectory \((u, x, y)\) of \((IV.1)\) on \(J_r\), with initial state \(x(\tau) = x_r\) and output satisfying \(P_{[\tau, t]}y \in H^1([\tau, t]; Y)\) for \(t \in J_r\); here \(\delta_0\) is point evaluation at \(s\).

Item 5) is proved in step five of the proof of \((I)\) Thm \(4.1)\). Hence, items 4)–6) are proved and 1) holds for trajectories as in 6) if \(G(\cdot)z \in C^1(J; X)\).

Step 3: Proving 1). Now we drop the additional smoothness assumption on \(G\), and we roughly follow the proof of \((II)\) Thm \(5.3(b-c)\). Let \(\Sigma_n\) be defined as \(\Sigma\), but using the averaged function \(G_n\) in \((III.7)\), instead of \(G\), so that \(T_{\tau}(t, \tau)w\) tends uniformly to some \(T_{\tau}(t, \tau)w\) in \(H\) on \(A_{[a, b]}\) for compact \([a, b] \subset J\) and all \(w \in H\). Then \(T_{\tau}\) has the structure \((II.8)\) and the operator families in \(T_{\tau}\) inherit causality \((II.4)\) from those in \(\Sigma_n\), so that \(T_{\tau}\) is the Lax-Phillips evolution family of a well-posed system \(\Sigma_t\) by Thm \((II.3)\).

For \((u, x, y)\) an arbitrary classical trajectory of \((IV.1)\):

\[
x(t) = (I - A_{-1})^{-1}(I + P(t)G(t))x(t) - P(t)\dot{x}(t) + (I - A_{-1})^{-1}Bu(t),
\]

where the first term is in \(C(J_r; \text{dom}(A))\) which is contained in \(C(J_r; Z)\) due to the continuity of the embedding \(\text{dom}(A) \to Z\), and the second term is in \(C(J_r; Z)\) since \((I - A_{-1})^{-1}B \in L(U, Z)\); see the discussion around \((II.11)\).
Now moreover assume that \((x(\tau), u) \in V(\tau)\). Further let \((u, x_n, y_n)\) be the unique classical trajectory of (IV.1) with \(G\) replaced by \(G_n\), such that \(x_n(\tau) = x_\tau := x(\tau)\); then

\[
x_n(t) = T_n(t, \tau)x_\tau + \Phi_n(t, \tau)u,
\]

\(\mathbf{P}_{[\tau, b]} y_n = \Psi_n(b, \tau)x_\tau + \Phi_n(b, \tau)u, \quad b \in J_\tau.\) (IV.6)

Letting \(n \to \infty\), we get from the construction of \(\Sigma_1\) that \(x_n \to x\) uniformly on \([\tau, b] \subset J_\tau\) and \(\mathbf{P}_{[\tau, b]} y_n \to y_\infty = \Psi_n(b, \tau)x_\tau + \Phi_n(b, \tau)u \in L^2([\tau, b]; U)\), so that \((u, x_\infty, y_\infty)\) is a trajectory of \(\Sigma_1\) on \([\tau, b] \subset x_\infty(\tau) = x_\tau\). We next prove that \(x_\infty = x\) and \(y_\infty = \mathbf{P}_{[\tau, b]} y\).

As \(\mathbf{P}(\cdot)^{-1}\mathbf{A} + \mathbf{G}(n)\) generates \(\mathfrak{T}_n\) and \((x(\tau), u) \in V(\tau), (IV.8), (IV.2)\) and (II.11) give

\[
\dot{x}(t) = P(t)^{-1} (A_n x_n(t) + Bu(t)) + G_n(t)x_n(t),
\]

\[y_n(t) = \begin{bmatrix} \delta_{0} & 0 \\ \bar{y} & x_\tau \\ \bar{S}_u & u \end{bmatrix} T_n(t, \tau),
\]

Step 4: \(\mathfrak{T}_1\) has the properties in (IV.12) and possibly those in (IV.14). When \(G\) is strongly continuously differentiable, \(A_1(t)\) generates an evolution semigroup \(\mathfrak{T}_1\) with time interval \(J\), by (IV.11) in order to prove that \(\mathfrak{T}_1 = \mathfrak{T}_1\), fix \(t \in J, \tau < t\), and \(x_\tau \in \text{dom}(A)\) arbitrarily. Then \(\bar{x}(t) := \mathfrak{T}_1(t, \tau)x_\tau, \quad t \in J_\tau\), solves (IV.14). By defining \(\tilde{y}(t) := C\bar{x}(t), t \in J_\tau\) get that \((0, \bar{x}, \bar{y})\) is a classical trajectory of (IV.1) on \(J_\tau\) with \(\dot{x}(\tau) = x_\tau\). Since \((x_\tau, 0) \in V(\tau)\), there is only one such trajectory by step 2, and \(\bar{x}(t) = \mathfrak{T}_1(t, \tau)x_\tau\) for all \(t \in J_\tau\). This proves that \(\mathfrak{T}_1(t, \tau)\) and \(\mathfrak{T}_1(t, \tau)\) coincide on the dense subspace \(\text{dom}(A)\) of \(X\), and by the boundedness of these operators, \(\mathfrak{T}_1(t, \tau) = \mathfrak{T}_1(t, \tau)\) on all of \(X\), for all \((t, \tau) \in \Delta_J\).

Now, even if \(G\) is only strongly continuous, \(\mathbf{P}(\cdot)^{-1}\mathbf{A}\) generates the Lax-Phillips evolution family of some well-posed system \(\{U, T(\cdot, t)\}\) by step 2, and by what we just proved, \(U\) is generated by \(P(\cdot)^{-1} \mathbf{A}\) and it has all the properties asserted in (IV.13). By (IV.12) the Lax-Phillips evolution family \(\mathfrak{T}_1\) constructed in step 2 satisfies the equation

\[
\begin{bmatrix} 0 & I & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{bmatrix} \Sigma(t, \tau) \begin{bmatrix} 0 \\ z \\ 0 \end{bmatrix} = \begin{bmatrix} 0 & I & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{bmatrix} \Sigma(t, \tau) \begin{bmatrix} 0 \\ z \\ 0 \end{bmatrix} \quad \text{and by (IV.13) and the definition of } \Phi, \text{ this equals (IV.14).}
\]

and by uniqueness in (IV.14), Since \(\mathfrak{T}_1\) inherits local evolution boundedness from \(\Sigma_1, \mathfrak{T}_1\) is equal to the evolution family in (IV.14) hence it has all the asserted properties.

Step 5: Proving 2). Define \(x(t)\) as in (2), but with \((x_\tau, u) \in V(\tau)\) such that \(\sup u \in J_\tau\) w.l.o.g. and define \(x_n\) by (IV.6).

Then the calculations in step 3 give that \(x(t) = \lim_{n \to \infty} x_n(t)\) in \(X\), uniformly on \([\tau, b] \subset \{b \in J_\tau\}\). By (IV.7), \(x_n(t) - x_\tau\) equals

\[
\int_{\tau}^{t} P(s)^{-1} (A_n x_n(s) + Bu(s)) + G_n(s)x_n(s) ds
\]

in \(X_\infty\), and letting \(n \to \infty\), (IV.19) gives that \(G_n x_n \to Gx\) uniformly on \([\tau, t]\) too, so that

\[
x(t) - x_\tau = \int_{\tau}^{t} A_{1,n}(s) x(s) + Bu(s) ds.
\]

For arbitrary \(x_\tau \in X\) and \(u \in L^2(J_\tau; U), x \in C(J_\tau; X)\) which implies that \([\tau, b] \ni t \to A_{1,n}(t) x(t) + Bu(t)\) is in \(L^2([\tau, b]; X_{-1})\) for all compact \([\tau, b] \subset J\). Approximating \((x_\tau, u)\) by elements in \(V(\tau)\) and using that convergence in \(L^2\) implies convergence in \(L^1\) on compact intervals in (IV.8), together with local uniform convergence of state trajectories due to the local uniform boundedness of \(\mathfrak{T}_1\) and \(\Phi_1\), we obtain that (IV.8) still holds. Hence, \(x \in C(J_\tau; X) \subset L^2_{loc}(J_\tau; X_{-1})\) is a primitive of the \(L^2_{loc}(J_\tau; X_{-1})\) function \(\dot{x}(t) = A_{1,n}(t) x(t) + Bu(t)\).

Step 6: Proving 3). Let \((x_\tau, u) \in V(\tau)\) be arbitrary. By step 2, the functions \(x_n \in C(J_\tau; X)\) and \(y_n \in L^2_{loc}(J_\tau; Y)\) determined by (IV.6) satisfy (IV.5) with \(G_n\) instead of \(G\). Letting \(n \to \infty\), we get from step 4 that \((u, x, y)\) determined by (IV.5) satisfy (IV.5), due to the uniform convergence of \(x_n\) to \(x\) and of \(G_n x_n\) to \(Gx\) on \([\tau, t]\). Approximating as in step 4, we extend (IV.5) to arbitrary \((x_\tau, u) \in X \times L^2(J_\tau; U)\). □
Under stronger regularity assumptions on $P(\cdot)$ and $G(\cdot)$, we have the following representation formulas:

**Proposition IV.2.** Assume that $P(\cdot)z \in C^2(J; X)$ and that $G(\cdot)z, G(\cdot)^*z \in C^1(J; X)$ for all $z \in X$. Let $\tau \in J$ with $\tau < \sup J$ and $t \in J_r$.

The operators $T_t(\cdot, \tau)$ have unique extensions to $\mathfrak{T}_{\tau}^{-1}(t, \tau) \in \mathcal{L}(X_{\tau-1},X_{\tau-1})$ which are locally uniformly bounded. For all $x_0 \in X$, $T_t(\cdot, 0)x_0$ is in $C^1((\inf J, t]; X_{\tau-1})$,

$$\frac{\partial}{\partial t} T_t(t, \tau) x_0 = -\mathfrak{T}_{\tau}^{-1}(t, \tau) A_{\tau}(\tau) x_0.$$

For all $x_r \in \text{dom}(A)$,

$$\Psi_t(t, \tau)x_r = s \mapsto C T_t(s, \tau)x_r, \quad \tau \leq s \leq t,$$

and for all $(0, u) \in V(\tau)$,

$$\Phi_t(t, \tau)u = \int_0^t T_t(s, \tau) P(s)^{-1} B u(s) \, ds \tag{IV.1}$$

$$(\Psi_t(t, \tau)u)(s) = C \int_0^s T_t(t, \tau) P(s)^{-1} B u(s) \, ds + D u(s), \quad s \in [\tau, t],$$

where the integrals are in $X_{\tau-1}$. The representation formula for $\Phi_t$ in fact holds for all $u \in L^2_{loc}(J; U)$.

**Proof.** The first assertion follows from the proof of [IV Prop. 2.8(b)] with some minor modifications: $P(\cdot)^{-1}z \in C^2(J; X)$ for all $z \in X$ and then the backward analogue of Prop. III.5 gives that $A_{\tau}(\tau)t^* = A^*P(\tau)^{-1} + G(\tau)t^*$ with $\text{dom}(A_{\tau}(\tau)t^*) = P(\tau) \text{ dom}(A^*)$ generates the backward evolution family $T_t^*$ with time interval $J$, such that

$$\Delta J \ni (t, \tau) \mapsto A^*P(\tau)^{-1} T_t(t, \tau)^* (I - A^*P(\tau)^{-1})^{-1} z$$

is continuous in $X$, for all $z \in X$. Then

$$T(t, \tau) := (P(\tau) - A^*)P(\tau)^{-1} T_t(t, \tau)^* (I - A^*P(\tau)^{-1})^{-1}$$

is strongly continuous on $\Delta J$ and by the uniform boundedness principle, $\|T(t, \tau)\| \leq K_{[a, b]}$ on $[a, b]$ for some $K_{[a, b]}$ depending on the compact $[a, b] \subset J$. Then

$$\|T_{\tau}^{-1}(t, \tau)\|_{\mathcal{L}(X_{\tau-1},X_{\tau-1}^\prime)} = \|T(t, \tau)^*\|_{\mathcal{L}(X_{\tau-1}^\prime,X_{\tau-1})} \leq K_{[a, b]}, \quad (t, \tau) \in \Delta_{[a, b]},$$

with $T_{\tau}^{-1}(t, \tau)$ the dual of $T_t(t, \tau)^*$. The first assertion now follows from the density of $X$ in $X_{\tau-1}$. Then the second assertion follows as in the proof of [IV Prop. 4.2(b)]

Let $x_r \in \text{dom}(A)$; then $(x_r, 0) \in V(\tau)$ and by Thm [IV.1] there is a unique classical trajectory $(0, x, y)$ of (IV.1) on $J_r$ with $x(\tau) = x_r$. This trajectory moreover satisfies

$$x(t) = T_t(t, \tau)x_r \quad \text{and} \quad P(\tau, t) y = \Psi_t(t, \tau)x(t),$$

where the latter is in $C((\tau, t]; Y)$. Then, for $s \in [\tau, t]$,

$$\Psi_t(t, \tau)x_r(s) = y(s) = C x(s) = C T_t(s, \tau)x_r.$$

Recalling that $C = \overline{C}$ and that $P(\tau, t) y = \Psi_t(t, \tau)x_r$ by Thm [IV.1], we get the representation formula for $\Psi_t$.

For the other assertions, by using Thm [IV.1] in the proof of [IV Prop. 4.2(b)], we get for $(0, u) \in V(\tau)$, in $X_{\tau-1}$,

$$\frac{\partial}{\partial s} T_t(s, \tau) \Phi_t(s, \tau) u = T_{\tau}^{-1}(t, s) P(s)^{-1} B u(s),$$

and integration now gives the representation formula for $\Phi_t(t, \tau)u$ for $(0, u) \in V(\tau)$. By Thm [IV.1] $x := \Phi_t(t, \tau)u \in C(\tau; Z)$ is the state trajectory of (IV.1) corresponding to $(0, u) \in V(\tau)$, and the output $y \in C(\tau; Y)$ of (IV.1) is

$$(\Phi_t(t, \tau)u)(s) = y(s) = C \Phi_t(s, \tau) u + D u(s),$$

i.e., the representation formula for $\Phi_t(t, \tau)u$ is correct.

By the boundedness of $\Phi_t(t, \tau)$, density, the uniform boundedness on $[\tau, t]$ of $T_{\tau}^{-1}(t, s) P(s)^{-1} B$ from $U$ into $X_{\tau-1}$, and the fact that convergence in $L^2$ implies convergence in $L^1$ on $[\tau, t]$, the representation formula for $\Phi_t$ is correct even for all $u \in L^2(J; U)$. Observing that the integration in the representation formula happens over the compact interval $[\tau, t]$, we get the representation formula for all $u \in L^2_{loc}(J; U)$.

**B. Multiplicative perturbation from the right**

The two preceding results have counterparts in the case of a multiplicative perturbation from the right. In the remainder of this section, we are concerned with the system

$$\begin{pmatrix} x(t) \\ y(t) \end{pmatrix} = \begin{pmatrix} A_1 P(t) + G(t) & B \\ C P(t) & D \end{pmatrix} \begin{pmatrix} x(t) \\ u(t) \end{pmatrix},$$

where again $\begin{pmatrix} A_1 & B \\ C & D \end{pmatrix}$ is passive. The Lax-Phillips evolution family $\mathfrak{T}_r$ of this system will be associated to the generator family $\mathfrak{A}_r(t) := \mathfrak{P}(t) + \mathfrak{G}(t)$, see (IV.7), which equals

$$\mathfrak{A}_r(t) \begin{pmatrix} y(t) \\ x_0 \\ u \end{pmatrix} = \begin{pmatrix} A_1 P(t) + G(t) & 0 & B \\ 0 & 0 & 0 \\ C P(t) & D & 0 \end{pmatrix} \begin{pmatrix} x(t) \\ u(t) \\ u \end{pmatrix},$$

with $\text{dom}(\mathfrak{A}_r(t)) = \mathfrak{P}(t)^{-1} \text{ dom}(\mathfrak{A})$, $t \in J$.

We have the following weaker analogue of Thm [IV.1]

**Theorem IV.3.** Let $\tau \in J$ be such that $\tau < \sup J$. There is a well-posed system $\Sigma_r = \begin{pmatrix} \Sigma_r^1 & \Sigma_r^2 \\ \Sigma_r^3 & \Sigma_r^4 \end{pmatrix}$ with time interval $J_r$ and Lax-Phillips evolution family $\mathfrak{T}_r$, such that $\mathfrak{T}_r$ has the properties asserted in Thm [III.3] and moreover:

1) For $x_r \in X$ and $u \in L^2(J_r; X)$, the function

$$x(t) := T_r(t, \tau)x_r + \Psi_r(t, \tau)u, \quad t \in J_r$$

is in $H^1_{loc}(J_r; X_{\tau-1})$ and it satisfies

$$\dot{x}(t) = A_{\tau}(\tau)x(t) + B u(t)$$

in $X_{\tau-1}$ for almost all $t \in J_r$, where $A_{\tau}(\tau)$ is the main operator in (IV.9).

2) Every classical trajectory $(u, x, y)$ of (IV.9) with time interval $J_r$ satisfies $P(\cdot) x(\cdot) \in C(\tau; Z)$, with $Z$ given in (II.10).

3) Every classical trajectory of (IV.9) with time interval $J_r$ is uniquely determined by $x(\tau)$ and $u$, and it satisfies the power inequality (IV.A) and the energy inequality (IV.B), both with equality if $\Sigma_r$ preserves energy.

4) The Lax-Phillips evolution family $\mathfrak{T}_r$ of $\Sigma_r$ is generated by $\mathfrak{A}_r(t), t \in J$, in the sense of Def [III.1].

5) For every $x_r$ and $u$ with $(P(\tau) x(\tau), u) \in V(\tau)$, there is a (unique) classical trajectory $(x, y, u)$ of (IV.9) on $J_r$.
with \( x(\tau) = x_\tau \). The output satisfies \( y \in H^1_{\text{loc}}(J; Y) \), and \((u, x, y)\) is also a trajectory of \( \Sigma_r \).

**Proof.** The proof is similar to that of Thm IV.1 First establish 3). Next, temporarily assume that \( P(\cdot) z \in C^2(J; X) \) and \( G(\cdot) z \in C^1(J; X) \) for all \( z \in X \). Then use Prop. III.5 instead of Thm III.1 and \( (P(\tau) x(\tau), u) \in V(\tau) \) instead of \((x(\tau), u) \in V(\tau)\), in step one of the proof of Thm IV.1 to get items 4) and 5), apart from the claim that \((u, x, y)\) is also a trajectory of \( \Sigma_r \). Item 2) is proved like the corresponding statement in Thm IV.1.

The classical trajectory \((u, x, y)\) of \((IV.9)\) that was constructed in the previous paragraph is also a trajectory of \( \Sigma_r \). Namely, by \((IV.5)\) for \( \Sigma_r \) and \((III.8)\), we get that

\[
\begin{align*}
\left\{ y(t) = \delta_r x(\tau, t)x+\delta_r x(\tau, t)u, \\
x(t) = T_r(t, \tau)x+\Phi_r(t, \tau)u, \quad t \in J_r;
\right.
\]

\[
\text{then (II.4), (IV.5) and the choice of u give that}
\]

\[
\begin{align*}
x(t) = T_r(t, \tau)x+\Phi_r(t, \tau)u, \\
P(\tau, t)u = \Phi_r(t, \tau)x+\Phi_r(t, \tau)u, \\
\end{align*}
\]

\[
\text{for all u0 \in H, where \( \tilde{\xi}_l \) is the strong limit of \( \tilde{\xi}_n \). Since \( \tilde{\xi}_n \) is associated to a well-posed system, so are \( \tilde{\xi}_l \) and \( \Sigma_r \); see the proof of Thm IV.1 step 3, and the proof of (II Prop. 4.3.a).}
\]

Thm III.4 and (II.14) give, for \( u \in L^2(J; U) \),

\[
\frac{\partial}{\partial t} \Phi_r(t, \tau)u = P(t)^{-1} \frac{\partial}{\partial t} \Phi_l(t, \tau)u
\]

\[
+ \int_t^\tau A_{-1,r}(t) T_r(s, t) P(s)^{-1} \Phi_l(s, t)u ds,
\]

and using Thm IV.1 with (II.4.17), we get that this equals \( A_{-1,r}(t) \Phi_l(t, \tau)u + Bu(t) \) which is in \( C(J_r; X) \subset L^2_{\text{loc}}(J_r; X) \) as a function of \( t \). By Thm III.4, \( T_r(t, \tau)x \in C^1(J_r; X) \subset H^1_{\text{loc}}(J_r; X) \) and \( \frac{\partial}{\partial t} T_r(t, \tau)x = A_{-1,r}(t) T_r(t, \tau)x \). Hence, 1) holds.

The proof is complete once we have established that \( T_r \) equals the evolution family in Thm III.4 then \( T_r \) has the properties asserted in Thm III.4 and in the smooth case even those in Prop. III.5. For an arbitrary \( x \in X \), we apply \([0 \quad I \quad 0]\) to (IV.11) with \( w_0 := \begin{bmatrix} 0 \\ 0 \end{bmatrix} \), from the left,

\[
\begin{align*}
T_r(t, \tau)x_\tau = P(t)^{-1} T_r(t, \tau)P(\tau)x_\tau
\end{align*}
\]

\[
+ \int_t^\tau P(t)^{-1} T_r(t, s)P(s) T_r(s, \tau)x_\tau ds.
\]

By (III.20), \( T_r \) satisfies (III.23), and by uniqueness, \( T_r \) is the same evolution family as in Thm III.4.

There are also representation formulas for multiplicative perturbation from the right, in case of smoother \( P(\cdot) \) and \( G(\cdot) \).

**Proposition IV.4.** Assume that \( P(\cdot) z \in C^2(J; X) \) and that \( G(\cdot) z, G(\cdot)^{\cdot} z \in C^1(J; X) \) for all \( z \in X \). Let \( r \in J \) with \( r < \sup J \) and \( t \in J_r \).

The operators \( T_r(t, \tau) \) have unique extensions to \( \mathbb{T}_{-1,r}(t, \tau) \) \( \mathcal{L}(X_{-1,r}; X^*_{-1,r}) \) which are locally uniformly bounded. The function \( \tau \mapsto T_r(t, \tau)x_\tau, \tau \in J \) with \( \tau \leq t \), is continuously differentiable in \( X_{-1,r} \), and

\[
\frac{\partial}{\partial \tau} T_r(t, \tau)x_\tau = -\mathbb{T}_{-1,r}(t, \tau)A_{-1,r}(\tau)x_\tau. \quad \text{(IV.12)}
\]

For all \( x_r \in P(\tau)^{-1} \text{dom}(A) \),

\[
\Psi_r(t, \tau)x_\tau = \mathbb{T}_{-1,r}(t, \tau)A_{-1,r}(\tau)x_\tau,
\]

and for all \((0, u) \in V(\tau)\),

\[
\Phi_r(t, \tau)u = \mathbb{T}_{-1,r}(t, \tau)Bu(\tau) ds
\]

\[
\text{for all u \in L^2(J; U)}.
\]

**Proof.** The claims on the extensions of \( T_r(t, \tau) \) follow as in the proof of Prop IV.2 because the backward version of Thm III.1 gives that \( A^*_l(\tau) = P(t)^{-1} + G(\tau)^* \text{dom}(A^*_l(\tau)) = \text{dom}(A^*_l) \) generates the backward evolution family \( T^*_r \) with time interval \( J \). Then also, for all \( x \in X \) and \( z \in \text{dom}(A^*_l) \),

\[
\frac{\partial}{\partial \tau} \langle T_r(t, \tau)x_\tau, z \rangle_{X_{-1,r}} = \langle \frac{\partial}{\partial \tau} T_r(t, \tau)z \rangle_{X_{-1,r}}^1,
\]

and we next prove that the weak derivative is strong. We have

\[
\|\mathbb{T}_{-1,r}(t, \tau)(A_{-1,r}(t, \tau)B(\tau) + G(\tau))x_\tau \|
\]

\[
- \|\mathbb{T}_{-1,r}(t, \tau)x_\tau \| \leq \| -\mathbb{T}_{-1,r}(t, \tau)A_{-1,r}(t, \tau)B(\tau) x_\tau \|
\]

\[
+ \| -\mathbb{T}_{-1,r}(t, \tau)G(\tau)x_\tau - \mathbb{T}_{-1,r}(t, \tau)G(\tau)x_\tau \|
\]

\[
\text{for all u \in L^2(J; U)}.
\]

For the strong continuity of \( T_r \) and the local uniform boundedness of \( \mathbb{T}_{-1,r} \), this proves (IV.12) and then the representation formulas can be proved the same way as the corresponding formulas in Prop IV.2.

\[\square\]

**V. A time-varying wave equation**

This section is concerned with the time-varying wave equation, on a bounded \( n \)-dimensional Lipschitz domain, whose boundary \( \partial \Omega \) has been split into a reflecting part \( \Gamma_0 \) and a part \( \Gamma_1 \) used for control and observation. We assume that \( \Gamma_0 \) and \( \Gamma_1 \) are relatively open with boundaries of measure zero within \( \partial \Omega \). We do not make the restrictive assumption that
also shown that he restricted normal trace operator \(\gamma\) may then define \(\gamma\) has a continuous extension on \(\Omega\), so that these norms of the gradient, and \(H\) norm of the gradient, \(\Omega\) is densely \(\rho\) and \(T\), the example is not covered by \([2]\) either.

In order to formulate the PDE \((\text{V.1})\) in operator theory language, so that we can prove its well-posedness, we need to recall the setting of \([3]\). We equip \(H^1(\Omega)\) with the graph norm of the gradient, and \(H^{\text{div}}(\Omega)\) is the space of all elements of \(L^2(\Omega)^n\), whose \((\text{distribution})\) divergence lies in \(L^2(\Omega)\), also equipped with the graph norm (see \([20]\)), so that these two spaces are Hilbert. For the definition of the fractional-order Hilbert space \(H^{1/2}(\partial\Omega)\) on the boundary of \(\Omega\), which is continuously embedded in \(L^2(\partial\Omega)\), see \([21]\) §13.5. Then

\[
W := \left\{ h \in H^{1/2}(\partial\Omega) \mid h|_{\Gamma_0} = 0 \right\}
\]

is Hilbert with the inherited norm, as the orthogonal projection onto \(L^2(\Gamma_0)\) in \(L^2(\partial\Omega)\) is bounded, \(W\) is continuously and densely embedded in \(L^2(\Gamma_1)\). \(\text{Thm} 13.6.10, (13.5.3)\). We may then define \(W'\) as the dual of \(W\) with pivot space \(L^2(\Gamma_1)\).

The Dirichlet trace \(\gamma_0\) maps \(H^1(\Omega)\) continuously onto \(H^{1/2}(\partial\Omega)\), and therefore the subspace

\[
H^{1}_0(\Omega) := \left\{ g \in H^1(\Omega) \mid g|_{\Gamma_0} = 0 \right\}
\]

is Hilbert with the norm inherited from \(H^1(\Omega)\). Furthermore, \(\gamma_0\) maps \(H^{1}_0(\Omega)\) continuously onto \(W\). In \([3]\) App. 1, it was also shown that he restricted normal trace operator

\[
\nu \mapsto (\nu \cdot u)|_{\Gamma_1} : C^\infty(\Omega)^n \rightarrow L^2(\Gamma_1)
\]

has a continuous extension \(\gamma_\perp\) that maps \(H^{\text{div}}(\Omega)\) onto \(W'\).

In order to write the wave equation as a "physically motivated" scattering passive system in the sense of \([4]\), we denote

\[
H := L^2(\Omega)^n, \quad E := L^2(\Omega), \quad E_0 := H^{1}_0(\Omega), \quad U := Y := L^2(\Gamma_1), \quad L := -\nabla|_{E_0} \in \mathcal{L}(E_0; H), \quad K := \sqrt{2b\gamma_0}|_{E_0} \in \mathcal{L}(E_0; U), \quad G(t) := \begin{bmatrix} 0 & 0 \\ 0 & \rho(t)/\rho(t) - Q(t)/\rho(t) \end{bmatrix} \in \mathcal{L}(H \times E), \quad P(t) := \begin{bmatrix} T(t) & 0 \\ 0 & 1/\rho(t) \end{bmatrix} \in \mathcal{L}(H \times E),
\]

where \(G(t)\) and \(P(t)\) are pointwise multiplication by the given functions of \(\xi\), so that, e.g.,

\[
(P(t)x)(\xi) = P(t, \xi) x(\xi), \quad \xi \in \Omega,
\]

\((\text{V.2})\) for all \(t \in J\) and \(x \in H \times E = L^2(\Omega)^{n+1}\). Here \(H, E,\) and \(U\) are identified with their duals. The space \(E_0\) is densely and continuously contained in \(E\). We take \(E_0'\) to be the dual of \(E_0\) with pivot space \(E\) and denote the bounded dual of \(L\) by \(L' \in \mathcal{L}(H; E_0')\). We can of course also consider \(L\) as a densely defined unbounded operator on \(E\) and in this case we would denote its unbounded adjoint on \(E\) by \(L^*\).

With the notation introduced above, we can interpret the PDE \((\text{V.1})\) as a time-varying boundary control system \([22]\)

\[
\begin{aligned}
\dot{x}(t) &= \mathcal{L}(t)x(t), \\
u(t) &= \mathcal{G}(t) + G(t), \\
\mathbb{E}(t) := \begin{bmatrix} 0 \\ \nabla z_0 / \rho(t) \end{bmatrix} \in \mathcal{L}(H \times E),
\end{aligned}
\]

\((\text{V.3})\)

by introducing the state \(x(t) := \begin{bmatrix} \nabla z(t) / \rho(t) \end{bmatrix} \) and the operators

\[
\mathcal{L}(t) := \begin{bmatrix} 0 \\ \nabla \end{bmatrix} P(t) + G(t),
\quad \mathcal{G}(t) := \begin{bmatrix} 1 \\ 1 \end{bmatrix} [\gamma \perp b^2 \gamma_0] P(t),
\quad \mathbb{E}(t) := \begin{bmatrix} 1 \\ 1 \end{bmatrix} [\gamma \perp -b^2 \gamma_0] P(t),
\]

with the common domain

\[
Z(t) := P(t)^{-1} \begin{bmatrix} H^{\text{div}}(\Omega) \\ H^{1}_0(\Omega) \end{bmatrix},
\]

\((\text{V.4})\)

By \([3]\) §4, the boundary control system \((\text{V.3})\) is a (scattering) conservative boundary control system in case \(P(t) = I\) and \(G(t) = 0\) for \(t \geq \tau\). In this case, we omit \((t)\) from the notation as the system becomes time invariant, and then \([22]\) Thm 2.3 gives that the mapping \([\mathbb{E}] [\mathbb{E}]^{-1}\) from \([x(t)] [u(t)]\) to \([\dot{x}(t)] [y(t)]\) in \((\text{V.3})\), defined on \([\mathbb{E} Z] Z\) in \((\text{V.4})\), with \(P(t) = I\).

We next recall the following integration by parts formula from \([3]\) (A5): for all \(f \in H^{\text{div}}(\Omega)\) and \(g \in H^{1}_0(\Omega),\)

\[
\langle \text{div} f, g \rangle_{L^2(\Omega)} + \langle f, \nabla g \rangle_{L^2(\Omega)^n} = \langle \gamma_\perp f, \gamma_0 g \rangle_{W', W}.
\]

\((\text{V.6})\)
With this formula, we can obtain the action of the bounded dual $L'$ on the dense subspace $H^{\text{div}}(\Omega)$ of its domain $L^2(\Omega)^n$:

**Corollary V.1.** With $K_0 := \gamma_0|_{E_0} \in \mathcal{L}(E_0;U)$, we have

$$L'f = \text{div } f - K_0^*\gamma_1 f, \quad f \in H^{\text{div}}(\Omega). \quad (V.7)$$

Moreover, $K_0^*$ is injective.

**Proof.** Using (V.6), for $w \in E_0 = H^1_0(\Omega)$ and $f \in H^{\text{div}}(\Omega)$:

$$\langle w, L'f + K_0\gamma_1 f \rangle_{E_0, E_0} = \langle \nabla w, f \rangle_{L^2(\Omega)^n} + \langle \gamma_0 w, \gamma_1 f \rangle_{L^2(\Omega)} = \langle w, \text{div } f \rangle_{L^2(\Omega)} = \langle w, f \rangle_{E_0, E_0},$$

which implies (V.7). Finally, if $K_0^*g = 0$ then

$$0 = \langle h, K_0^*g \rangle_{E_0, E_0} = \langle \gamma_0 h, g \rangle_U$$

for all $h \in E_0$, and consequently $g \in U \cap \gamma_0 E_0 = \{0\}$. \(\square\)

Cor. [V.1] makes it easy to prove that (V.3) satisfies

$$\left[\begin{array}{c} \mathcal{A} \mathcal{B} - I \\ \mathcal{C} \end{array}\right] \left[\begin{array}{c} t \\ \xi \end{array}\right]^{-1} = \left[\begin{array}{c} \mathcal{A} P(t) + G(t) \\ \mathcal{C} P(t) \end{array}\right],$$

where

$$\mathcal{A} := \left[\begin{array}{cc} 0 & -L \\ L' & -\frac{1}{2}K'K \end{array}\right], \quad \mathcal{B} := \left[\begin{array}{c} 0 \\ R' \end{array}\right],$$

$$\mathcal{C} := \left[\begin{array}{c} 0 \\ -K \end{array}\right], \quad \text{dom}(\mathcal{A}) = \text{dom}(\mathcal{C}) = \left[\begin{array}{c} H \\ E_0 \end{array}\right].$$

Then $A \subset \mathcal{A} \subset A_{-1}$, where (with $X := H \times E$)

$$A := \mathcal{A}_{(\text{dom}(\mathcal{A}) \cap \text{dom}(\mathcal{C}))}, \quad \text{dom}(A) := \{x \in X \mid \mathcal{A}x \in X\},$$

and $A_{-1}$ is the unique extension of $A$ to an operator in $\mathcal{L}(X;X_{-1})$; see [I] for details.

The unbounded operator

$$\left[\begin{array}{c} L \\ K \end{array}\right] : E \supset \text{dom}(\left[\begin{array}{c} L \\ K \end{array}\right]) = E_0 \rightarrow \left[\begin{array}{c} H \\ U \end{array}\right]$$

is closed, since the Hilbert space $E_0$ is equipped with the graph norm of $-L$ and $K \in \mathcal{L}(E_0;U)$. In case $T(t) = I$, $\rho = 1$ and $Q(t) = Q \geq 0$ for all $t \geq 0$, then

$$\left[\begin{array}{c} \hat{x}(t) \\ \hat{y}(t) \end{array}\right] = \left[\begin{array}{c} \mathcal{A} P(t) + G(t) \\ \mathcal{C} P(t) \end{array}\right] \left[\begin{array}{c} x(t) \\ u(t) \end{array}\right], \quad t \geq \tau, \quad (V.9)$$

with the operators defined in (V.8) and $G(t) = \left[\begin{array}{cc} 0 & 0 \\ 0 & -Q \end{array}\right]$, is indeed in the “physically motivated” class, with state space $X = H \times E$, by [I] Thm 1.1. The connection between (V.8) and (V.1) is made more precise in the next result, which states that the equations have the same classical solutions.

**Theorem V.2.** Assume that $T$ and $T^{-1}$ are such that the functions $T^{(z)} z = T^{(z)} z$ are in $C^1(J; L^2(\Omega)^n)$ for all $z \in L^2(\Omega)^n$, cf. (V.2). Also, assume that the multiplications by $\rho(t)$ and $1/\rho(t)$ are strongly in $C^1(J; L^2(\Omega))$, and that $Q(z)$ is strongly in $C(J; L^2(\Omega))$. Then $\Sigma_w$ in (V.9) is a well-posed system with state space $X = L^2(\Omega)^n \times L^2(\Omega)$, input/output space $U = L^2(\Gamma_1)$, and properties 1)-3) in Theorem IV.3.

Now additionally assume that $T(z)$ and $\rho(z)$ are strongly in $C^2$ and that $Q(z)$ is strongly in $C^4$. Then $\Sigma_w$ has properties 4)-5) in Thm IV.3. Moreover, for every $z_0, z_1 \in H^1_{\text{loc}}(\Omega)$, $\tau \in J$ with $\tau < \sup J$, and $u \in H^1_{\text{loc}}(J; U)$, such that

$$T(\tau) \nabla z_0 \in H^{\text{div}}(\Omega)$$

and

$$\gamma_\perp T(\tau) \nabla z_0 + b^2 \gamma_\perp z_1 = \sqrt{2b} u(\tau),$$

there is a unique solution of (V.1) on $J_\tau$ that satisfies

$$z \in C^2(J_\tau; L^2(\Omega)) \cap C^1(J_\tau; H^1_{\text{loc}}(\Omega)).$$

(IV.10)

For this solution, $(u, x, y)$ is a classical trajectory of (IV.9), where $x(t) := \left[\begin{array}{c} \nabla v(t) \\ \rho(t) \hat{z}(t) \end{array}\right], \ t \in J_\tau$, the output signal satisfies $y \in H^1_{\text{loc}}(J_\tau; Y)$, and the power balance

$$\frac{d}{dt} \langle T(t) \nabla v(t), \nabla v(t) \rangle_H + \frac{d}{dt} \langle \rho(t) \hat{z}(t), \hat{z}(t) \rangle_E$$

$$+ \|y(t)\|_Y^2 = \langle u(t), 0 \rangle_H + \langle \hat{T}(t) \nabla v(t), \nabla v(t) \rangle_H$$

(IV.11)

holds for $t \in J_\tau$, together with the corresponding integrated energy balance. In this case, if $Q(\cdot)$ is a multiplication operator like (V.2), then the assertions in Prop. IV.4 hold.

A multiplication operator $M(\cdot)$ of the type (V.2) satisfies $M(\cdot)f \in C^k(J; L^2(\Omega)^k)$ for all $f \in L^2(\Omega)^k$ if all its component functions $M_a(\cdot, \xi) \in C^k(J; L^2(\Omega))$. If additionally $M(t, \xi) \geq \delta I$ for some $\delta > 0$ independent of $t \in J$ and $\xi \in \mathbb{R}$, then also $M(\cdot)^{-1} f \in C^k(J; L^2(\Omega)^k)$ for all $f \in L^2(\Omega)^k$; see (III.2). Even, thus the smoother assumptions on $T(\cdot)$, $\rho(\cdot)$ and $Q(\cdot)$ in Thm IV.2 are satisfied in the following interesting particular case, cf. [I] pp. 177-181:

A rigid object moves inside the domain $\Omega$, with center point $\eta(t)$ moving according to $\hat{\eta}(t) = a(t, \eta(t))$, where the acceleration field $a \in C(\bar{J} \times \Omega; \mathbb{R}^n)$; then $\eta \in C^2(\bar{J}; \Omega)$. In the moving object, the physical parameters $\rho(t, \xi), T(t, \xi)$ and $Q(t, \xi)$ depend only on the distance to the center point, in a twice continuously differentiable manner; they are of the form

$$(M(t)f)(\xi) = m(\|\eta(t) - \xi\|^2) f(\xi), \ t \in J, \ \xi \in \Omega,$$

with $m \in C^2(\mathbb{R})$ such that $m(\cdot) \geq \delta I$ for some $\delta > 0$. \(\square\)

**Proof.** For the first assertion, use the first, less smooth part of Thm IV.3 on (V.9). For the second assertion, note that $P(t)$ and $Q(t)$ satisfy the standing assumptions (III.1). For the last statement, note that if $Q(\cdot)$ is a multiplication operator then it is self-adjoint, and hence $G(\cdot)^*$ inherits strong continuity from $G(\cdot)$. It suffices to prove the rest of the statements for compact intervals $[a, b] \subset J$; then, in particular, $H^1([a, b]; U) = H^1_{\text{loc}}([a, b]; U)$. Assume that $T(\cdot), \rho(\cdot) \in C^2$ and $Q(\cdot) \in C^1$, strongly.

Let $z_0, z_1$ and $u$ be as in the second assertion. Then $x_\tau := \left[\begin{array}{c} \nabla z_0 \\ \rho(t) \hat{z} \end{array}\right]$ satisfies $P(t)x_\tau, u \in V(\tau)$, since $A \subset A_{-1}$, and

$$A_{-1} P(t)x_\tau + B u(\tau) = \left[\begin{array}{c} \nabla z_1 \\ \text{div } \left(T(\tau) \nabla z_0\right) \end{array}\right] \in \left[\begin{array}{c} L^2(\Omega)^n \\ L^2(\Omega) \end{array}\right] = X.$$
unique $x$ and $y$, such that $(u, x, y)$ is a classical trajectory of \( (V.9) \) with \( x(\tau) = x_\tau \), and this trajectory satisfies \( (IV.4) \) with equality, \( y \in H^1(J_\tau; Y) \) and \( P(\cdot) x(\cdot) \in C(J_\tau; Z) \). Writing \( x(t) = [x_2(t) \atop x_2(t)] \) and defining

\[
z(t) := z_0 + \int_\tau^t \frac{x_2(s)}{\rho(s)} \, ds,
\]  

\[(V.12)\]

we get \( x(t) = \begin{bmatrix} \nabla z_2(t) \\ \rho(t) \end{bmatrix}, \) and then \( (IV.4) \) specializes to \( (V.11) \). The definition of classical trajectory now gives that

\[
x(t), \dot{x}(t) = \begin{bmatrix} \nabla \dot{z}(t) \\ \dot{\rho}(t) \dot{z}(t) + \rho(t) \ddot{z}(t) \end{bmatrix} \in C \left( J_\tau; \left[ L^2(\Omega)^n \atop L^2(\Omega) \right] \right).
\]

Thus \( (V.10) \) holds with \( H^1 \) instead of \( H^1_{\nu_0}(\Omega). \)

We next prove that \( (u, z, y) \) is a solution of \( (V.1) \) in the \( L^2 \) sense. Using the formula for \( \dot{x}(t) \), \( (V.8) \) and Cor. \( V.1 \) we get

\[
\rho(t) \ddot{z}(t) = L^T(t) \nabla z(t) - \frac{1}{2} K^T K \dot{z}(t) + K^T u(t) - Q(t) \dot{z}(t)
\]

\[= \text{div} T(t) \nabla z(t) - Q(t) \dot{z}(t) - K_0^* \gamma \nabla T(t) \nabla z(t) - K_0^* b^2 \nabla \dot{z}(t) + K_0^* \sqrt{2b} u(t),
\]

as an equality in \( E_\nu^\prime \). Applying this functional to an arbitrary test function, \( \varphi \in C^\infty(\Omega) \) with compact support in \( \Omega \), we get that \( \rho(t) \ddot{z}(t) + Q(t) \dot{z}(t) = \text{div} T(t) \nabla z(t) \) in the sense of distributions. From \( P(\cdot) x(\cdot) \in C(J_\tau; Z) \) and \( (V.2) \), we moreover get that \( \dot{z}(t) \in H^1_{\nu_0}(\Omega) \) and \( T(t) \nabla z(t) \in H_{\nu_0}^\prime(\Omega) \), so that in fact \( \rho(t) \ddot{z}(t) = \text{div} T(t) \nabla z(t) - Q(t) \dot{z}(t) \) in \( L^2(\Omega) \), i.e., the first and fourth lines of \( (V.1) \) are satisfied in \( L^2 \). Then the injectivity of \( K_0^* \) and the preceding display gives line 2 of \( (V.1) \), as an equality in \( L^2(\Gamma_1) \), and line 3 follows from \( (V.8) \):  

\[
\sqrt{2b} r(t) = \gamma \nabla_T(T(t) \nabla z(t)) + b^2 \gamma \dot{z}(t) - 2b^2 \gamma z(t),
\]

in \( L^2(\Gamma_1) \). By \( (V.12) \), we have \( z(\tau) = z_0 \) and \( \dot{z}(\tau) = x_2(\tau)/\rho(\tau) = z_1 \).

It remains to prove uniqueness. Let \( (u, z, y) \) be a classical solution of \( (V.1) \) with \( (V.10) \). Defining \( x(t) := \begin{bmatrix} \nabla z(t) \\ \rho(t) \end{bmatrix}, \) we get from the calculations above that \( (u, x, y) \) is a classical trajectory of \( (V.9) \) with \( x(\tau) = \begin{bmatrix} x_2(\tau) \\ \rho(\tau) z_1 \end{bmatrix} \) and the given input signal \( u \). By Thm \( IV.3 \), such a trajectory is unique.

The detour via \( (V.5) \) was needed only in order to establish that the solution space of \( (V.9) \) with \( P(t) = I \) and \( G(t) = 0 \) is \( Z \) in \( (V.4) \), which in turn was needed to prove that \( \dot{z}(t) \big|_{\Gamma_0} = 0 \) for \( t \geq \tau \). We can unfortunately not prove a complete analogue of [2] Thm 6.3 for mild trajectories of \( (V.9) \), as we were unable to establish \( (I.5) \) for mild trajectories in Thm \( IV.3 \).

VI. ACKNOWLEDGMENT

The author thanks George Weiss for suggesting this very interesting research project. The research was partially funded by the foundation of Ruth and Nils-Erik Stenbäck.
