Abstract. We introduce the weighted CFG constraint and propose a propagation algorithm that enforces domain consistency in $O(n^3 |G|)$ time. We show that this algorithm can be decomposed into a set of primitive arithmetic constraints without hindering propagation.

1 Introduction

One very promising method for rostering and other domains is to specify constraints via grammars or automata that accept some language. We can specify constraints in this way on, for instance, the number of consecutive night shifts or the number of days off in each 7 day period. With the Regular constraint [4], we specify the acceptable assignments to a sequence of variables by a deterministic finite automaton. One limitation of this approach is that the automaton may need to be large. For example, there are regular languages which can only be defined by an automaton with an exponential number of states. Researchers have therefore looked higher up the Chomsky hierarchy. In particular, the CFG constraint [8, 6] permits us to specify constraints using any context-free grammar. In this paper, we consider a further generalization to the weighted CFG constraint. This can model over-constrained problems and problems with preferences.

2 The weighted CFG constraint

In a context-free grammar, rules have a left-hand side with just one non-terminal, and a right-hand side consisting of terminals and non-terminals. Any context-free grammar can be written in Chomsky form in which the right-hand size of a rule is just one terminal or two non-terminals. The weighted WCFG($G, W, z, [X_1, \ldots, X_n]$) constraint holds iff an assignment $X$ forms a string belonging to the grammar $G$ and the minimal weight of a derivation of $X$ less than or equal to $z$. The matrix $W$ defines weights of productions in the grammar $G$. The weight of a derivation is the sum of production weights used in the derivation. The WCFG constraint is domain consistent iff for each variable, every value in its domain can be extended to an assignment satisfying the constraint.

We give a propagator for the WCFG constraint based on an extension of the CYK parser to probabilistic grammars [3]. We assume that $G$ is in Chomsky normal form and with a single start non-terminal $S$. The algorithm has two stages. In the first, we construct a dynamic programming table $V[i,j]$ where an element $A$ of $V[i,j]$ is a potential non-terminal that generates a substring $[X_i, \ldots, X_{i+j}]$. We compute a lower bound $l[i, j, A]$ on the minimal weight of a derivation from $A$. In the second stage, we move from $V[1,n]$ to the bottom of table $V$. For an element $A$ of $V[i,j]$, we compute an
upper bound \( u[i, j, A] \) on the maximal weight of a derivation from \( A \) of a substring \( [X_i, \ldots, X_n] \). We mark the element \( A \) if \( l[i, j, A] \leq u[i, j, A] \). The pseudo-code is presented in Algorithm 1. Lines 2–5 initialize \( l \) and \( u \). Lines 6–16 compute the first stage, whilst lines 20–29 compute the second stage. Finally, we prune inconsistent values in lines 30–31. Algorithm 1 enforces domain consistency in \( O(|G|n^3) \) time.

Algorithm 1 The weighted CYK propagator

1: procedure WCYK-ALG(\( G, W, z, [X_1, \ldots, X_n] \))
2:  for \( j = 1 \) to \( n \) do
3:      for \( i = 1 \) to \( n - j + 1 \) do
4:          for each \( A \in G \) do
5:              \( l[i, j, A] = z + 1 \); \( u[i, j, A] = -1 \);
6:      for \( i = 1 \) to \( n \) do
7:          \( V[i, j] = \{ A | A \rightarrow a \in G, a \in D(X_i) \} \)
8:          for \( A \in V[i, j] \) s.t \( A \rightarrow a \in G, a \in D(X_i) \) do
9:              \( l[i, 1, A] = \min\{l[i, 1, A], W[A \rightarrow a]\} \);
10:     for \( j = 2 \) to \( n \) do
11:        for \( i = 1 \) to \( n - j + 1 \) do
12:          \( V[i, j] = \emptyset \);
13:          for \( k = 1 \) to \( j - 1 \) do
14:              \( V[i, j] = V[i, j] \cup \{ A | A \rightarrow BC \in G, B \in V[i, k], C \in V[i + k, j - k] \} \)
15:              for each \( A \rightarrow BC \in G \) s.t \( B \in V[i, k], C \in V[i + k, j - k] \) do
16:                  \( l[i, j, A] = \min\{l[i, j, A], W[A \rightarrow BC] + l[i, k, B] + l[i + k, j - k, C]\} \);
17:          if \( S \notin V[1, n] \) then
18:              return 0;
19:      mark (1, \( n \), \( S \)); \( u[1, n, \emptyset] = z \);
20:     for \( j = n \) downto 2 do
21:         for \( i = 1 \) to \( n - j + 1 \) do
22:             for \( A \) such that \((i, j, A)\) is marked do
23:                 for \( k = 1 \) to \( j - 1 \) do
24:                     for each \( A \rightarrow BC \in G \) s.t \( B \in V[i, k], C \in V[i + k, j - k] \) do
25:                         if \( W[A \rightarrow BC] + l[i, k, B] + l[i + k, j - k, C] \geq u[i, j, A] \) then
26:                             continue;
27:                             mark \((i, k, B)\); mark \((i + k, j - k, C)\);
28:                             \( u[i, k, B] = \max\{ u[i, k, B], u[i, j, A] - l[i + k, j - k, C] - W[A \rightarrow BC] \} \);
29:                             \( u[i + k, j - k, C] = \max\{ u[i + k, j - k, C], u[i, j, A] - l[i, k, B] - W[A \rightarrow BC] \} \);
30:         \( D(X_i) = \{ a \in D(X_i) | A \rightarrow a \in G, (i, 1, A) \text{ is marked and } W[A \rightarrow a] \leq u[i, 1, A] \} \);
31:     return 1;

3 Decomposition of the weighted CFG constraint

As an alternative to this monolithic propagator, we propose a simple decomposition with which we can also enforce domain consistency. A decomposition has several advantages. For example, it is easy to add to any constraint solver. As a second example, decomposition gives an efficient incremental propagator, and opens the door to advanced techniques like nogood learning and watched literals. The idea of the decomposition is to introduce arithmetic constraints to compute \( l \) and \( u \). Given the table \( V \) obtained by Algorithm 1, we construct the corresponding \( AND/OR \) directed acyclic graph (DAG) as in [7]. We label an \( OR \) node by \( n(i, j, A) \), and an \( AND \) node by \( n(i, j, k, A \rightarrow BC) \). We denote the parents of a node \( nd \) as \( PRT(nd) \) and the children as \( CHD(nd) \). For each node two integer variables are introduced to compute \( l \) and \( u \).
For each OR-node $nd$, these are $l_O(nd)$ and $u_O(nd)$, whilst for an AND-node $nd$, these are $l_A(nd)$, $u_A(nd)$. 

For each AND node $nd = n(i, j, k, A \rightarrow BC)$ we post a constraint to connect $nd$ to its children $CHD(nd)$:

$$l_A(nd) = \sum_{n_c \in CHD(nd)} l_O(n_c) + W[A \rightarrow BC]$$ (1)

For each OR node $nd = n(i, j, A)$ we post constraints to connect $nd$ to its children $CHD(nd)$:

$$l_O(nd) = \min_{n_c \in CHD(nd)} \{ l_A(n_c) \}$$ (2)

$$u_O(nd) = u_A(n_c), n_c \in CHD(nd)$$ (3)

For each OR node $nd = n(i, j, A)$ we post a set of constraints to connect $nd$ to its parents $PRT(nd)$ and siblings:

$$u_O(nd) = \max_{n_p \in PRT(nd)} \{ u_A(n_p) - l_O(n_{sb}) - W[P] \},$$ (4)

where $P = B \rightarrow AC$ or $B \rightarrow CA$, $n_p = n(r, q, t, P)$ is the parent of $nd = n(i, j, A)$ and $n_{sb} = n(i_1, j_1, C)$.

Finally, we introduce constraints to prune $X_i$. For each leaf of the DAG that is an OR node $nd = n(i, 1, a)$, we introduce:

$$\begin{align*}
a &\in D(X_i) \Rightarrow 0 \leq l_O(nd) \leq z \quad (5) \\
a &\notin D(X_i) \Rightarrow l_O(nd) > z \quad (6) \\
l_O(nd) > u_O(nd) \Rightarrow a \notin D(X_i) \quad (7)
\end{align*}$$

As the maximal weight of a derivation is less than or equal to $z$ we post:

$$u_O(n(1, n, S)) \leq z$$ (8)

Bounds propagation will set the lower bound of $l_O(n(i, j, A))$ to the minimal weight of a derivation from $A$, and the upper bound on $u_O(n(i, j, A))$ to the maximum weight of a derivation from $A$. We forbid branching on variables $l_{A|O}$ and $u_{A|O}$ as branching on $l_{A|O}$ would change the weights matrix $W$ and branching on $u_{A|O}$ would add additional restrictions to the weight of a derivation. Bounds propagation on this decomposition enforces domain consistency on the WCFG constraint. If we invoke constraints in the decomposition in the same order as we compute the table $V$, this takes $O(n^3|G|)$ time. For simpler grammars, propagation is faster. For instance, as in the unweighted case, it takes just $O(n|G|)$ time on a regular grammar.

We can speed up propagation by recognizing when constraints are entailed. If $l_O(nd) > u_O(nd)$ holds for an OR node $nd$ then constraints (4) and (2) are entailed. If $l_A(nd) > u_A(nd)$ holds for an AND node $nd$ then constraints (1) and (3) are entailed. To model entailment we augmented each of these constraints in such a way that if $l_O(nd) > u_O(nd)$ or $l_A(nd) > u_A(nd)$ hold then corresponding constraints are not invoked by the solver.
4 The Soft CFG constraint

We can use the WCFG constraint to encode a soft version of CFG constraint which is useful for modelling over-constrained problems. The soft CFG($G, z, [X_1, \ldots, X_n]$) constraint holds if the string $[X_1, \ldots, X_n]$ is at most distance $z$ from a string in $G$. We consider both Hamming and edit distances. We encode the soft CFG($G, z, [X_1, \ldots, X_n]$) constraint as a weighted CFG($G', W, z, [X_1, \ldots, X_n]$) constraint. For Hamming distance, for each production $A \to a \in G$, we introduce additional unit weight productions to simulate substitution:

\[
\{ A \to b, W[A \to b] = 1 \mid A \to a \in G, A \to b \notin G, b \in \Sigma \}
\]

Existing productions have zero weight. For edit distance, we introduce additional productions to simulate substitution, insertion and deletion:

\[
\{ A \to b, W[A \to b] = 1 \mid A \to a \in G, A \to b \notin G, b \in \Sigma \} \cup \\
\{ A \to \varepsilon, W[A \to \varepsilon] = 1 \mid a \in \Sigma \} \cup \\
\{ A \to Aa, W[A \to Aa] = 1 \mid a \in \Sigma \} \cup \\
\{ A \to aA, W[A \to aA] = 1 \mid a \in \Sigma \}
\]

To handle $\varepsilon$ productions we modify Alg. 1 so loops in lines (13),(23) run from 0 to $j$.

5 Experimental results

We evaluated these propagation methods on shift-scheduling benchmarks [2, 1]. A personal schedule is subject to various regulation rules, e.g. a full-time employee has to have a one-hour lunch. This rules are encoded into a context-free grammar augmented with restrictions on productions [7, 5]. A schedule for an employee has $n = 96$ slots represented by $n$ variables. In each slot, an employee can work on an activity ($a_i$), take a break ($b$), lunch ($l$) or rest ($r$). These rules are represented by the following grammar:

\[
S \to RPR, f_P(i, j) \equiv 13 \leq j \leq 24, \quad P \to WbW, L \to LL[l], f_L(i, j) \equiv j = 4 \\
S \to RFR, f_F(i, j) \equiv 30 \leq j \leq 38, \quad R \to rR[r], \quad W \to A_i, f_W(i, j) \equiv j \geq 4 \\
A_i \to a_iA_i[a_i, f_A(i, j) \equiv open(i)], \quad F \to PLP
\]

where functions $f(i, j)$ are restrictions on productions and $open(i)$ is a function that returns 1 if the business is opened at $i$th slot and 0 otherwise. To model labour demand for a slot we introduce Boolean variables $b(i, j, a_k)$, equal to 1 if $j$th employee performs activity $a_k$ at $i$th time slot. For each time slot $i$ and activity $a_k$ we post a constraint $\sum_{k=1}^m x(i, j, a_k) > d(i, a_k)$, where $m$ is the number of employees. The goal is to minimize the number of slots in which employees worked.

We used Gecode 2.0.1 for our experiments and ran them on an Intel Xeon 2.0Ghz with 4Gb of RAM. In the first set of experiments, we used the weighted CFG($G, z_j, X$), $j = 1, \ldots, m$ with zero weights. Our monolithic propagator gave similar results to the

---

1 We would like to thank Claude-Guy Quimper for his help with the experiments
unweighted CFG propagator from [7]. Decompositions were slower than decompositions of the unweighted CFG constraint as the former uses integers instead of Booleans.

In the second set of experiments, we assigned weight 1 to activity productions, like $A_i \rightarrow a_i$, and post an additional cost function $\sum_{j=1}^m z_j$ that is minimized. $\sum_{j=1}^m z_j$ is the number of slots in which employees worked. Results are presented in Table 1. We improved on the best solution found in the first model in 4 benchmarks and proved optimality in one. The decomposition of the weighted CFG constraint was slightly slower than the monolithic propagator, while entailment improved performance in most cases.

| A | # | m | cost | time | bt | BT | cost | time | bt | BT | Opt | Imp |
|---|---|---|------|------|----|----|------|------|----|----|-----|-----|
| 1 | 2 | 4 | 107  | 5    | 0  | 8652 | 107  | 7    | 0  | 5926 | 107  | 7   | 0   | 11521 |

| 1 | 10 | 9 | –   | –    | –  | 10871 | –    | –    | –  | –    | –    | –   | –   | –    |

Table 1. All benchmarks have one-hour time limit. $|A|$ is the number of activities, $m$ is the number of employees, $cost$ shows the total number of slots in which employees worked in the best solution, $time$ is the time to find the best solution, $bt$ is the number of backtracks to find the best solution, $BT$ is the number of backtracks in one hour, $Opt$ shows if optimality is proved, $Imp$ shows if a lower cost solution is found by the second model.
