COMBINATORIAL CLASSES ON $\bar{M}_{g,n}$ ARE TAUROLOGICAL

GABRIELE MONDELLO

Abstract. The combinatorial description via ribbon graphs of the moduli space of Riemann surfaces makes it possible to define combinatorial cycles in a natural way. Witten and Kontsevich first conjectured that these classes are polynomials in the tautological classes. We answer affirmatively to this conjecture and find recursively all the polynomials.

Introduction

0.1. History. Let $g$ and $n$ be nonnegative integers such that $2g - 2 + n > 0$ and set $P = \{p_1, \ldots, p_n\}$. Denote by $\mathcal{M}_{g,P}$ the moduli space of compact Riemann surfaces $S$ of genus $g$ with an injection $P \hookrightarrow S$.

In the early ’80s a combinatorial description of $\mathcal{M}_{g,P}$ was discovered. Thanks to ideas mainly due to Mumford and Thurston, it was proven that, if $S$ is a compact oriented surface of genus $g$ and $P$ is nonempty, then there is a homeomorphism between the Teichmüller space $\mathcal{T}(S,P)$ and a certain subset $|A^0(S,P)|$ of the realization of the arc complex $A(S,P)$, which is equivariant with respect to the action of the modular group $\Gamma_{S,P}$. This gives a homeomorphism between $\mathcal{M}_{g,P} \times \Delta_P$ and the orbicellular complex $|A^0(S,P)|/\Gamma_{S,P}$, which can be equivalently expressed in terms of the ribbon graph complex $\mathcal{M}_{g,P}^{\text{comb}}$.

This combinatorial description led to impressive results about the topology of $\mathcal{M}_{g,P}$: among the others, the computation of the virtual cohomological dimension of $\Gamma_{S,P}$ by Harer (see [Har86]), the computation of the virtual Euler characteristic of $\Gamma_{S,P}$ by Harer-Zagier and Penner (see [HZZ86] and [Pen88]), computations and estimates of Weil-Petersson volumes (see for instance [Pen92], [KMZ96] and [Gru01]) and Witten’s conjecture by Kontsevich (see [Kon92]).

There are (at least) two different ways to define the above homeomorphism. While combinatorially equivalent, they are geometrically very different. The first way uses the hyperbolic geometry of noncompact Riemann surfaces with finite volume and is due to Penner (see [Pen92]) and Bowditch-Epstein (see [BE88]).

The second way uses results of Jenkins (see [Jen57]) and Strebel (see [Str67]) on meromorphic quadratic differentials, in particular results of existence and uniqueness for differentials with closed trajectories, and is due
to Harer, Mumford and Thurston (see [Har86]). We refer to [Str84] for a detailed treatment of this subject, but see also [HM79].

The conjecture of Witten and Kontsevich (see [Kon92]), which can be formulated in both the combinatorial descriptions equivalently, says that the $W$ cycles, which are defined as the locus of ribbon graphs with assigned valencies of their vertices, are Poincaré dual to the tautological classes $\kappa$ on the moduli space. In fact, these subcomplexes $W$ determine homology classes with noncompact support on $\mathcal{M}_{g,P}$; so we naturally obtain cohomology classes with rational coefficients by Poincaré duality, because $\mathcal{M}_{g,P}$ is an orbifold. More precisely, the conjecture says that a multiple of $\kappa_r$ is Poincaré dual to $W_{2r+3}$, whose support is the locus of ribbon graphs with one vertex of valency at least $2r+3$.

More generally, let $m_* = (m_{-1}, m_0, m_1, \ldots)$ be a sequence of nonnegative integers such that $\sum_{i \geq -1} (2i+1)m_i = 4g-4+2n$ and let $\mathcal{M}_{m_*}^{\text{comp}} \subset \mathcal{M}_{g,P}^{\text{comp}}$ be the orbicellular subcomplex of ribbon graphs whose top-dimensional orbicells are parametrized by ribbon graphs with $m_i$ vertices of valency $2i+3$. Notice, by the way, that $\mathcal{M}_{m_*}^{\text{comp}} \simeq \mathcal{M}_{g,P}^{\text{comp}}$ if $m_* = (0, 4g-4+2n, 0, 0, \ldots)$. For every $l = (l_1, \ldots, l_{p_0}) \in \mathbb{R}_+^P$ denote by $\mathcal{M}_{m_*}^{\text{comp}}(l)$ the subset of graphs in $\mathcal{M}_{m_*}^{\text{comp}}$ such that the $p_i$-th hole has perimeter $2l_{p_i}$. Remark that $\mathcal{M}_{m_*}^{\text{comp}}(\mathbb{R}_+^P)$ is homeomorphic to $\mathcal{M}_{m_*}^{\text{comp}}(l) \times \mathbb{R}_+^P$ for every $l \in \mathbb{R}_+^P$.

Kontsevich [Kon92] and Penner [Pen93] proved that for every $l \in \mathbb{R}_+^P$ the orbicompact $\mathcal{M}_{m_*}^{\text{comp}}(l)$ has an orientation, and so the classifying map $\mathcal{M}_{m_*}^{\text{comp}}(l) \to \mathcal{M}_{g,P}$ defines a homology class with noncompact support $W_{m_*}(l)$ on $\mathcal{M}_{g,P}$, that does not depend on the choice of $l \in \mathbb{R}_+^P$, and which will be called combinatorial class. Moreover, Kontsevich introduced combinatorial “compactifications” $\overline{\mathcal{M}}_{m_*}^{\text{comp}}$ which still have orientations and (in the case $m_{-1} = 0$) embed as subcomplexes $\overline{\mathcal{M}}_{m_*}^{\text{comp}} \hookrightarrow \overline{\mathcal{M}}_{g,P}^{\text{comp}}$; thus, they define cycles $\overline{W}_{m_*}(\mathbb{R}_+^P) \in H_*^{BM}(\overline{\mathcal{M}}_{g,P}^{\text{comp}}(\mathbb{R}_+^P); \mathbb{Q})$ in Borel-Moore homology and ordinary cycles $\overline{W}_{m_*}(l) \in H_*(\overline{\mathcal{M}}_{g,P}^{\text{comp}}(l); \mathbb{Q})$ for every $l \in \mathbb{R}_+^P$. In fact, $\overline{\mathcal{M}}_{g,P}^{\text{comp}}(l)$ is homeomorphic to a quotient $\overline{\mathcal{M}}_{g,P}$ of the Deligne-Mumford compactification $\overline{\mathcal{M}}_{g,P}$ for all $l \in \mathbb{R}_+$ and the class $\overline{W}_{m_*}(l)$ on $\overline{\mathcal{M}}_{g,P}$ does not depend on $l$. However, while $\overline{\mathcal{M}}_{g,P}$ is an orbifold and so virtual Poincaré duality holds and allows us to write equalities that mix rational homology and cohomology classes, $\overline{\mathcal{M}}_{g,P}$ might have ugly singularities, so it is not so easy to get a cohomology class on $\overline{\mathcal{M}}_{g,P}$. In any case, we will always consider homology and cohomology groups with rational coefficients in what follows.

**Conjecture** (Witten-Kontsevich [Kon92]). For every $m_* = (0, m_0, m_1, \ldots)$ such that $\sum_{i \geq -1} (2i+1)m_i = 4g-4+2|P|$, the class $W_{m_*}(P) \in H_*^{BM}(\mathcal{M}_{g,P})$ is Poincaré dual to a polynomial in the $\kappa$ classes $f_{m_*}(\kappa_1, \kappa_2, \ldots) \in H^*(\mathcal{M}_{g,P})$. 

First results towards a proof of the conjecture were obtained by Penner [Pen93]; using a result of Wolpert [Wol83] on the Weil-Petersson metric, he could deal with the case $W_5 = 12 \kappa_1$.

The approach of Arbarello and Cornalba [AC96] passes through matrix models, Di Francesco-Itzykson-Zuber’s theorem [DFIZ93] and Kontsevich’s compactification $\overline{M}_{g,P}$ and led to stronger results. In fact, they found a way to compute in principle all the $W_{m^*,P}$ in terms of the kappa classes and reported their results in lower codimensions, giving a strong evidence to the conjecture. For example, they discovered that on $\overline{M}_{g,P}$ the cycle $W_{(0,m_0,3,0,...),P}$ is dual to $288 \kappa_3 - 4176 \kappa_1 \kappa_2 + 20736 \kappa_3$. Looking at a number of results such as the previous one, they refined the conjecture as follows.

**Conjecture** ([AC96]). Consider the algebra of polynomials $\mathbb{Q}[t] := \mathbb{Q}[t_1, t_2, \ldots]$ where each $t_i$ has degree 1. Then for every $m_* = (0, m_0, m_1, \ldots)$ there exists a polynomial $f_{m_*} \in \mathbb{Q}[t]$ of degree $\sum_{i \geq 1} m_i$ such that

$$W_{m^*,P} = f_{m_*}(\kappa_1, \kappa_2, \ldots) \in H^*(\overline{M}_{g,P})$$

where $W_{m^*,P}$ is the Poincaré dual of $W_{m^*,P}$. Moreover $f_{m_*}$ looks like

$$f_{m_*}(t) = \prod_{i \geq 1} \left( \frac{(2i+1)!! \cdot m_i!}{m_i!} t_i^{m_i} + \text{terms of lower degree} \right).$$

In any event, the meaning of the other coefficients of $f_{m_*}$ was still obscure. Really, they compared the combinatorial classes and the kappa classes as functionals on the algebra generated by the $\psi$ classes, which are defined both on $\overline{M}_{g,P}$ and on $\overline{M}_{g,P}^{com}(l)$. In this way, they were able to compute the difference $W_{m^*,P} - f_{m_*}(\kappa)$ in some concrete cases up to some minor uncertainty.

In this paper we give an affirmative answer to the previous conjecture and we exhibit a formula that permits one to compute all the polynomials $f_{m_*}$ inductively on their degree.

Quite recently, K. Igusa [Igu02] [Igu03] and K. Igusa-M. Kleber [IK03] have proven very similar results by different methods.

**0.2. Contents of the paper.** We begin with some introductory material on the Teichmüller space and the moduli space of curves, the combinatorial description and the tautological classes.

Next, we introduce the combinatorial classes $\overline{W}_{m^*,P}$ on $\overline{M}_{g,P}$ and some generalized classes $\overline{W}_{m^*,\rho,P} \subset \overline{W}_{m^*,P \cup Q}$ on $\overline{M}_{g,P \cup Q}$ depending on a $\rho : Q \rightarrow \mathbb{Z}_{\geq -1}$, which are defined prescribing that every $q \in Q$ marks a vertex of valency at least $2\rho(q) + 3$.

After that, we lift the cycles $\overline{W}_{m^*,P}(l)$ on $\overline{M}_{g,P}^{com}$ to cycles on $\overline{M}_{g,P}$ (resp. the cycles $\overline{W}_{m^*,\rho,P}$ from $\overline{M}_{g,P \cup Q}^{com}$ to $\overline{M}_{g,P \cup Q}$). However, in order to do that, we have to pay a price. In fact, we do not obtain absolute homology classes of $\overline{M}_{g,P}$ (resp. $\overline{M}_{g,P \cup Q}$) but only homology classes relative to a certain
algebraic closed subset $\Sigma_{g,P} \subset \mathcal{M}_{g,P}$ (resp. $\Sigma^Q_{g,P} \subset \mathcal{M}_{g,P \cup Q}$), which in any case is contained in the boundary.

We remark that the $\mathcal{W}_{m_r,P}$ classes can be obtained by pushing $\mathcal{W}_{m_r,P}$ forward via a combinatorial analogue of the forgetful map $\pi_Q : \mathcal{M}_{g,P \cup Q} \to \mathcal{M}_{g,P}$. Hence, we first remark that $\mathcal{W}_{m_r,P}$ is Poincaré dual to a polynomial in the $\psi$ classes, if all nontrivalent vertices of the general ribbon graph of $\mathcal{W}_{m_r,P}$ are marked by $Q$. Then we obtain our result for any combinatorial class, because we know how $\psi$ classes behave under forgetful morphisms (Faber’s formula).

The simplest case is the class $\mathcal{W}_{2r+3}$ supported on the subcomplex of $P \cup \{q\}$-marked ribbon graphs in which $q$ marks a vertex of valency at least $2r + 3$. We prove that $\mathcal{W}_{2r+3}$ is Poincaré dual to $2^{r+1}(2r + 1)!\psi_q^{r+1}$ on $\mathcal{M}_{g,P \cup \{q\}}$; with a little more care we obtain also that $\mathcal{W}_{2r+3}$ is Poincaré dual to $2^{r+1}(2r + 1)!\kappa_r$ on $\mathcal{M}_{g,P}$, essentially because $(\pi_q)_*(\psi)^{r+1} = \kappa_r$.

Very roughly, we want to verify the above equality $\mathcal{W}_{2r+3} = 2^{r+1}(2r + 1)!\psi_q^{r+1}$ (where $(\psi_q^{r+1})$ is the Poincaré dual of $\psi_q^{r+1}$) by coupling both sides with a closed PL differential form $\eta$ on $\mathcal{M}_{g,P \cup \{q\}}$.

In this computation, we exploit a nice and explicit PL differential form $\overline{\omega}_q$ on $\mathcal{M}_{g,P \cup \{q\}}$ (found by Kontsevich), whose class pulls back to $\psi_q$ on $\mathcal{M}_{g,P \cup \{q\}}$.

Hence, the problem translates to showing that, for some perimeter lengths $\tilde{l}$ and $\tilde{l'}$, the equality

$$\int_{\mathcal{M}_{g,P \cup \{q\}}(\tilde{l})} \overline{\omega}_q^{r+1} \wedge \eta = 2^{r+1}(2r + 1)! \int_{\mathcal{W}_{2r+3}(\tilde{l'})} \eta + \int_{\mathcal{N}(\tilde{l'})} \eta$$

holds, where $\mathcal{N}(\tilde{l'})$ is a certain cycle sitting in the boundary. The main problem is that the combinatorial class $\mathcal{W}_{2r+3}$ is defined in the slices $\mathcal{M}_{g,P \cup \{q\}}(\tilde{l'})$ with $\tilde{l'} = 0$, while the differential form $\overline{\omega}_q$ is defined only on the slices $\mathcal{M}_{g,P \cup \{q\}}(\tilde{l})$ with $\tilde{l} > 0$.

The key idea to overcome this difficulty is to define a deformation retraction $\mathcal{H}^q_0$ that shrinks the $q$-th hole and so provides a bridge between the region $\{\tilde{l} > 0\}$ and the slice $\{\tilde{l} = 0\}$. In other words, $\mathcal{H}^q_0$ makes it possible to recover the combinatorial class $\mathcal{W}_{2r+3}$ as push-forward of $\overline{\omega}_q^{r+1}$. We remark that this $\mathcal{H}^q_0$ retracts some cells sitting in the interior of $\mathcal{M}_{g,P \cup \{q\}}$ to the boundary. Sometimes the curious behaviour of this map gives rise to some technical problems; nevertheless, it is a key tool in the proofs and it has the merit of being easily visualizable.

Once we have our retraction $\mathcal{H}^q_0$, we discover that, by simple reasons of degree, the restriction of the differential form $\overline{\omega}_q^{r+1} \wedge (\mathcal{H}^q_0)^* \eta$ on $\mathcal{M}_{g,P \cup \{q\}}(\tilde{l})$ is supported on the smallest subcomplex $\mathcal{Y}_{2r+3}(\tilde{l})$ that contains all the cells parametrized by ordinary ribbon graphs whose $q$-th hole is bordered by $2r+3$ edges.
Next, we dissect $Y_{2r+3}$ into subcomplexes $Y_{2r+3}^i$ according to the topology of the $q$-th hole. In this way, the restriction of $H_0^q$ to each $Y_{2r+3}^i$ is generically a fibration whose fibers $F^i$ are simplicial complexes of dimension $2r + 3$. Hence
\[ \int_{\bar{\mathcal{M}}_{g,P;\cup\{q\}}(\mathcal{I})} \varpi^q \wedge (H_0^q)^* \eta = \sum_i \int_{H_0^q(Y_{2r+3}^i(\mathcal{I}))} \eta \int_{F^i \cap \{q=\varepsilon\}} \varpi^q \]
and we get the result analyzing $H_0^q(Y_{2r+3}^i)$ and computing the integral on the fibers. We underline that, once the spaces and the machinery are set up, the actual calculation is really straightforward.

For example, the class $\overline{W}_{2r+3}$ arises as image of top-dimensional simplices when the hole $q$ is contractible, i.e. no edge borders the hole $q$ from both sides. In this case, the fiber is just one simplex (provided $r \geq 1$) and the integral on the fiber is exactly $\frac{(r+1)!}{(2r+2)!}$. Other top-dimensional simplices give rise to boundary terms.

Hence, in the case of combinatorial classes with only one nontrivalent vertex, the main result (in a slightly simplified version) is the following.

**Theorem A.** For any $g$ and $n \geq 1$, the equality
\[ \overline{W}_{2r+3} = \frac{(2r+2)!}{(r+1)!} (\psi^{r+1}_q)^* \]
holds in $H_{6g-6+2n-2r}(\mathcal{M}_{g,P;\cup\{q\}}, \partial \mathcal{M}_{g,P;\cup\{q\}})$ for every $r \geq -1$. Moreover, for $r \geq 1$ the equality
\[ \overline{W}_{2r+3} = 2^{r+1}(2r+1)!! \kappa_r^* \]
holds in $H_{6g-6+2n-2r}(\mathcal{M}_{g,P}, \partial \mathcal{M}_{g,P})$.

As an example, we have the following corollary which was already proven by Arbarello and Cornalba in a very different manner (see [AC96]).

**Corollary A.1.** For every $g$ and $|P| = n \geq 1$ such that $2g-2+n > 0$ the following equalities hold
\[ \overline{W}_5 + \delta^q_{irr} + \sum_{g',I \neq \emptyset,P} \delta^q_{g',I} = 12(\psi^2_q)^* \quad \text{in } H_{6g-8+2n}(\mathcal{M}_{g,P;\cup\{q\}}, \Sigma^q_{g,P}) \]
\[ \overline{W}_5 + \delta_{irr} + \sum_{g',I \neq \emptyset,P} \delta_{g',I} = 12\kappa_1^* \quad \text{in } H_{6g-8+2n}(\mathcal{M}_{g,P}, \Sigma^q_{g,P}) \]
where $\delta^q_{g',I}$ is the image of the morphism
\[ \mathcal{M}_{g',I;\cup\{p\}} \times \mathcal{M}_{0,\{q,q',q''\}} \times \mathcal{M}_{g-g',I;\cup\{p''\}} \rightarrow \mathcal{M}_{g,P;\cup\{q\}} \]
that glues $p'$ with $q'$ and $p''$ with $q''$ (analogously for $\delta_{irr}$).

Next, we pass to examine the case of a general combinatorial class $\overline{W}_{m_*}$.

As explained before, we recover them by pushing some $\overline{W}_{m_*}$ forward through a combinatorial version of the forgetful morphism $\pi_Q : \mathcal{M}_{g,P;\cup\{q\}} \rightarrow \mathcal{M}_{g,P;\cup\{q\}}$.

\[ \overline{W}_{m_*} = \frac{(2r+2)!}{(r+1)!} (\psi^{r+1}_q)^* \]
holds in $H_{6g-6+2n-2r}(\mathcal{M}_{g,P;\cup\{q\}}, \partial \mathcal{M}_{g,P;\cup\{q\}})$ for every $r \geq -1$. Moreover, for $r \geq 1$ the equality
\[ \overline{W}_{m_*} = 2^{r+1}(2r+1)!! \kappa_r^* \]
holds in $H_{6g-6+2n-2r}(\mathcal{M}_{g,P}, \partial \mathcal{M}_{g,P})$.

As an example, we have the following corollary which was already proven by Arbarello and Cornalba in a very different manner (see [AC96]).

**Corollary A.1.** For every $g$ and $|P| = n \geq 1$ such that $2g-2+n > 0$ the following equalities hold
\[ \overline{W}_5 + \delta^q_{irr} + \sum_{g',I \neq \emptyset,P} \delta^q_{g',I} = 12(\psi^2_q)^* \quad \text{in } H_{6g-8+2n}(\mathcal{M}_{g,P;\cup\{q\}}, \Sigma^q_{g,P}) \]
\[ \overline{W}_5 + \delta_{irr} + \sum_{g',I \neq \emptyset,P} \delta_{g',I} = 12\kappa_1^* \quad \text{in } H_{6g-8+2n}(\mathcal{M}_{g,P}, \Sigma^q_{g,P}) \]
where $\delta^q_{g',I}$ is the image of the morphism
\[ \mathcal{M}_{g',I;\cup\{p\}} \times \mathcal{M}_{0,\{q,q',q''\}} \times \mathcal{M}_{g-g',I;\cup\{p''\}} \rightarrow \mathcal{M}_{g,P;\cup\{q\}} \]
that glues $p'$ with $q'$ and $p''$ with $q''$ (analogously for $\delta_{irr}$).

Next, we pass to examine the case of a general combinatorial class $\overline{W}_{m_*}$.

As explained before, we recover them by pushing some $\overline{W}_{m_*}$ forward through a combinatorial version of the forgetful morphism $\pi_Q : \mathcal{M}_{g,P;\cup\{q\}} \rightarrow \mathcal{M}_{g,P;\cup\{q\}}$.
\( \mathcal{M}_{g,P} \). The proof works more or less as before, but a new phenomenon occurs when we shrink via \( \mathcal{H}_0^Q \) all the \( Q \)-marked holes. In fact, the cycles in the image of \( \mathcal{H}_0^Q \) do not depend only on the shape of a single hole \( q_i \in Q \), but also on the configuration of the \( Q \)-marked holes in the ribbon graph. For instance, in the case \( Q = \{q_1, q_2\} \), the map \( \mathcal{H}_0^{q_1,q_2} \) produces two different cycles if the two holes \( q_1 \) and \( q_2 \) “touch” each other (i.e. they have at least one vertex in common) or if they are detached. Hence, a careful combinatorial analysis is needed in order to prove the theorem for a general \( \mathcal{W}_{m_*,p,P} \).

The notations and the results about the classes \( \mathcal{W}_{m_*,p,P} \) are quite heavy, so here we content ourselves to state the theorem in the simpler case of \( \mathcal{W}_{m_*,p} \) and to defer to Section 8 for more refined results.

Choose \( \rho : Q \to \mathbb{N}_+ \) and \( m_* = (0, m_0, m_1, \ldots) \) such that \( m_0 \geq 0 \), \( m_i = \rho^{-1}(i) \) for \( i > 0 \) and \( \sum_{i \geq 0} (2i + 1)m_i = 4g - 4 + 2n \). Let \( \Psi_Q \) be the set of partitions of \( Q \) and for all \( \mu \subset Q \) define \( \rho_\mu = \sum_{q_i \in \mu} \rho(q_i) \).

**Theorem B** (simplified version). For any \( g \geq 0 \) and \( P \neq \emptyset \) such that \( 2g - 2 + |P| > 0 \), the following equality holds

\[
\sum_{M \in \Psi_Q} C(\rho, M) \mathcal{W}_{m_*(M),p} = (\pi_Q)_* \left[ \prod_{q \in Q} 2^{\rho(q)+1}(2\rho(q) + 1)!(\psi_{q}^{\rho(q)+1})^* \right]
\]

in \( H_*(\mathcal{M}_{g,p}, \partial \mathcal{M}_{g,p}) \), where

\[
m_i(M) = \begin{cases} m_0 & \text{if } i = 0 \\ |\{\mu \subset M | \rho_\mu = i\}| & \text{if } i \neq 0 \end{cases}
\]

and \( C(\rho, M) \) is an explicit integer coefficient that depends only on \( \rho \) and \( M \).

The theorem gives a recipe, which works inductively on \( |Q| \), to calculate all the coefficients of \( f_{m_*} \). As an example we have the following.

**Corollary B.2.** For every \( g \geq 0 \) and \( P \neq \emptyset \) such that \( 2g - 2 + |P| > 0 \) and for every \( a, b \geq 1 \), the following identity

\[
2^{\delta_{a,b}} \mathcal{W}_{2a+3,2b+3} = 2^{a+b+2}(2a + 1)!(2b + 1)!(\kappa_a^{*} \kappa_b^{*} + \kappa_{a+b}^{*}) - 2^{a+b+1}(2a + 2b + 3)\kappa_{a+b}^{*}
\]

holds in \( H_*(\mathcal{M}_{g,p}, \partial \mathcal{M}_{g,p}) \).

0.3. **Plan of the paper.** In the first section we recall a few facts on the Teichmüller space and the moduli space of curves and we introduce Kontsevich’s compactification \( \overline{\mathcal{M}}_{g,P} ^\Delta \) as a quotient of the product \( \overline{\mathcal{M}}_{g,P} \times \Delta_P \) of Deligne-Mumford compactification by \( \Delta_P = \{l \in \mathbb{R}_{\geq 0}^P | \sum_{p \in P} l_p = 1\} \). Moreover, we describe the fiber of the quotient map \( \xi : \overline{\mathcal{M}}_{g,P} \times \Delta_P \to \overline{\mathcal{M}}_{g,P} ^\Delta \).

In the second section we introduce the arc complex \( A(S, P) \) (following the presentation of Looijenga [Loo95]) and the ribbon graph complex \( \overline{\mathcal{M}}_{g,P} ^{comb} \).
COMBINATORIAL CLASSES ON $\overline{M}_{g,n}$ ARE TAUTOLOGICAL

(following Kontsevich [Kon92]) and we recall the equivalence of these two constructions (already present in [Loo95]) and Kontsevich’s isomorphism $\overline{M}_{g,P}^{\text{comb}} \cong \overline{M}_{g,P}^\Delta \times \mathbb{R}_+$. We follow the approach by means of quadratic differentials. However, since our tools and techniques are essentially combinatorial, there is an identical argument in the parallel setting in hyperbolic geometry.

In the third section we define the tautological classes and we recall the string and dilaton equations and, more generally, Faber’s formula which govern the push-forward of $\psi$ classes via the forgetful maps.

In the fourth section we introduce $\overline{M}_{m,P}^{\text{comb}}$ and their generalizations $\overline{M}_{m_*,p,P}^{\text{comb}}$. Moreover, we describe Kontsevich’s combinatorial representatives $\overline{\omega}$ of the $\psi$ classes and we recall how their (weighted) sum gives a sort of symplectic form and so an orientation form on these complexes.

In the fifth section we develop the main technical tools, namely the retraction $H^q_0$ in the simplest case and the combinatorial forgetful map $\pi^\text{comb}_q$, which are used in the proof of Theorem A contained in Section 6.

Parallelly, the seventh section extends the retraction and the combinatorial forgetful map to the case of many marked vertices; while, in the eighth section, we introduce combinatorial classes with rational tails and we prove the full version of Theorem B.

Finally, in the Appendix we describe Looijenga’s modification $\hat{A}(S,P)$ of the arc complex (see [Loo95]), that maps to the Deligne-Mumford compactification in a $\Gamma_{S,P}$-equivariant way, and we discuss how it might give a canonical way to lift the combinatorial classes to $\overline{M}_{g,P}$ without ambiguities.

Acknowledgements. I warmly thank my advisor Enrico Arbarello for having introduced me to the subject and for his constant support spanning many years. I also wish to thank Robert Penner for useful discussions, and Domenico Fiorenza and Riccardo Murri for valuable suggestions and remarks. Finally, I want to thank the referee for carefully reading the paper and for several comments and improvements.

1. Moduli spaces of curves and compactifications

Let $S$ be a compact connected oriented surface of genus $g$ and let $P \hookrightarrow S$ be an injection of $n$ points such that $\chi(S \setminus P) = 2 - 2g - n < 0$.

Definition 1.1. A family of $P$-pointed surfaces is a couple $(\pi, s)$ where $\pi : \mathcal{C} \to B$ is a proper differentiable submersion whose fibers are oriented connected surfaces and $\{s_p : B \to \mathcal{C}|p \in P\}$ is a collection of disjoint sections. An $(S,P)$-marking is an equivalence class of oriented diffeomorphisms $f : S \times B \xrightarrow{\sim} \mathcal{C}$ that commute with the projections onto $B$ and such that $f(p, b) = s_p(b)$ for every $p \in P$. Two markings $f \sim \tilde{f}$ are equivalent if and only if

$$\tilde{f}^{-1} \circ f : (S,P) \times B \to (S,P) \times B$$

is a vertically (i.e. over $B$) isotopic to the identity relatively to $P$. 

A conformal structure is an atlas such that the changes of coordinates are differentiable and preserve the angles. There is an obvious bijection between conformal structures and complex structures and between conformal structures and Riemannian metrics up to multiplication by a positive function.

Remark. By uniformization, the universal covering of a Riemann surface \( S \setminus P \) with negative Euler characteristic is isomorphic to the unit disk \( \Delta = \{ z \in \mathbb{C} \mid |z| < 1 \} \). Thus, the Poincaré metric \( \frac{4dz\,d\bar{z}}{(1-|z|^2)^2} \) on \( \Delta \) descends to a complete hyperbolic metric \( S \setminus P \) of finite volume with cusps at \( P \), which is unique because the analytic automorphisms of \( \Delta \) are isometries. Vice versa, given a complete hyperbolic metric of finite volume on \( S \setminus P \) one can associate a complex structure in a canonical way. As we are taking a conformal approach, we will not pursue the hyperbolic point of view in what follows.

Definition 1.2. Let \( (\pi, s) \) be a family of \( P \)-pointed surfaces. A conformal structure on \( (\pi, s) \) is a differentiable atlas of \( C \) which endows \( C_b \cup s_p(b) \) with a conformal structure for all \( b \in B \).

We say that two marked families \( (C, f) \) and \( (C', f') \) of \( P \)-pointed surfaces with conformal structure are isomorphic if there is a diffeomorphism \( t : C \to C' \) such that \( t \circ f' = f \) and the restriction to each fiber \( t_b : C_b \to C'_b \) is conformal outside the sections.

The Teichmüller functor \( \mathcal{T}_{S,P} : (\text{Top. Spaces}) \to (\text{Sets}) \) associates to every manifold \( B \) the set of isomorphism classes of \( (S, P) \)-marked families of \( P \)-pointed surfaces over \( B \) with conformal structure. It is represented by a complex manifold \( \mathcal{T}_{S,P} \) of (complex) dimension \( 3g - 3 + n \), which is diffeomorphic to a ball. Except in the case \( (g, n) = (0, 3) \) it is never compact.

The modular group \( \Gamma_{S,P} := \text{Diff}_+(S,P) / \text{Diff}_0(S,P) \) of connected components of the space of oriented diffeomorphisms of \( (S, P) \) acts on the \( (S, P) \)-markings and so on \( \mathcal{T}_{S,P} \). Its quotient is denoted by \( \mathcal{M}_{g,P} \) and classifies smooth families of \( P \)-pointed Riemann surfaces of genus \( g \) up to isomorphism. However this functor is not representable, so the topological quotient \( \mathcal{T}_{S,P} / \Gamma_{S,P} \) is only a coarse moduli space.

The functor \( \mathcal{M}_{g,P} \) admits a natural extension \( \overline{\mathcal{M}}_{g,P} \) that classifies flat families of stable \( P \)-pointed Riemann surfaces of (arithmetic) genus \( g \), where stable means that the singularities look like \( \{ xy = 0 \} \subset \mathbb{C}^2 \) in local analytic coordinates and that each connected component of the smooth locus has negative topological Euler characteristic. The functor \( \overline{\mathcal{M}}_{g,P} \) admits a coarse moduli space \( \overline{\mathcal{M}}_{g,P} \) which is a normal irreducible projective variety with quotient singularities and which contains \( M_{g,P} \) as a Zariski-dense open subset. It can be seen that \( \overline{\mathcal{M}}_{g,P} \) is in fact represented by an orbifold \( \overline{\mathcal{M}}_{g,P} \) which is connected and compact.

Now we want to introduce a different compactification \( \overline{\mathcal{M}}_{g,P} \) due to Kontsevich [Kon92] which will be very useful in what follows. Really, we slightly
modify Kontsevich’s construction as we realize our space as a quotient of $\mathcal{M}_{g,P} \times \Delta_P$ by an equivalence relation, where $\Delta_P := \{l \in \mathbb{R}_{\geq 0}^P | \sum_{p \in P} l_p = 1\}$.

If $(S, l)$ is an element of $\mathcal{M}_{g,P} \times \Delta_P$, then we say that an irreducible component of $S$ is positive (with respect to $l$) if it contains a point $p \in P$ such that $l_p > 0$. So we declare that $(S, l)$ is equivalent to $(S', l')$ if $l = l'$ and there is a homeomorphism of pointed surfaces $S \sim S'$ which is holomorphic on the positive components of $S$.

As this relation would not give back a Hausdorff space, we consider its closure, which can be described as follows.

We attach to every $S$ its dual graph $\gamma_S$, whose vertices are irreducible components and whose edges are nodes of $S$. Moreover, every vertex $v$ is labelled by a couple $(g_v, P_v)$, where $g_v$ is the geometric genus of $v$ and $P_v \subset P$ is the set of marked points lying on $v$. Given $(S, l)$ as before, consider the following two moves:

1. if two nonpositive vertices $v$ and $v'$ are joined by an edge $e$, then we can build a new graph discarding $e$, melding $v$ and $v'$ together to obtain a new vertex $w$ which we label with $(g_w, P_w) := (g_v + g_{v'}, P_v \cup P_{v'})$

2. if a nonpositive vertex $v$ has a loop $e$, we can make a new graph discarding $e$ and labelling $v$ with $(g_v + 1, P_v)$.

**Figure 1.** Two surfaces with different dual graphs
Applying these moves to $\gamma_S$ iteratively until the process ends, we are given back a reduced dual graph $\gamma^\text{red}_{S,l}$. Call $V_0(S,l)$ the subset of vertices $v$ of $\gamma^\text{red}_{S,l}$ such that $l_p = 0$ for every $p \in P_v$ and call $V_+(S,l)$ the subset of positive components of $S$.

![Figure 2. Dual graphs of surfaces in Fig. 1](image)

**Example.** Consider the nodal surfaces of genus 5 as in Fig. 1 and let $l$ be given in such a way that $l_{p_1} > 0$ and $l_{p_4} + l_{p_5} > 0$, but $l_{p_2} = l_{p_3} = 0$. Hence, components $w_1$, $w_2$ and $w_3$ in case (a) and $w$ in case (b) are nonpositive, while $v_1$ and $v_2$ are positive. Their associated dual graphs are obviously different (see Fig. 2); but in case (b) it is reduced, while in case (a) it is not. In fact, it is easy to check that both surfaces have the same reduced dual graph (which of course coincide with the dual graph of the surface (b)).

For every couple $(S,l)$ denote by $\bar{S}$ the quotient of $S$ obtained collapsing every nonpositive component to a point. We say that $(S,l)$ and $(S',l')$ are equivalent if $l = l'$ and there exist a homeomorphism $\bar{f} : \bar{S} \rightarrow \bar{S}'$ and an isomorphism $f^\text{red} : \gamma^\text{red}_{S,l} \sim \gamma^\text{red}_{S',l'}$ of reduced dual graphs such that $\bar{f}$ and $f^\text{red}$ are compatible and the restriction of $\bar{f}$ to each component is holomorphic.

Call $\Mt := \MgP \times \Delta_P / \sim$ the quotient and $\xi : \Mt \rightarrow \MgP$ the natural projection. Remark that $\Mt$ is compact and that $\xi$ commutes with the projection onto $\Delta_P$. For every $l$ in $\Delta_P$ we will denote by $\Mt(l)$ the subset of points of the type $[S,l]$ and we will write $\Mt(L)$ for $\cup_{l \in L} \Mt(l)$ where $L \subset \Delta_P$. Then it is easy to see that $\Mt(\Delta^o_P)$ is in fact homeomorphic to a product $\Mt(l) \times \Delta^o_P$ for any given $l \in \Delta^o_P$.

Finally notice that the fibers of $\xi$ are isomorphic to moduli spaces. More precisely, consider a point $[S,l]$ of $\Mt$ and call $Q_v$ the subset of half-edges of $\gamma^\text{red}_{S,l}$ incident on the vertex $v$ for every $v \in V_0(S,l)$. Thus $\xi^{-1}([S,l]) \cong \prod_{v \in V_0(S,l)} \Mt_{v \cup Q_v}.$
2. Combinatorial description

Fix a compact connected oriented surface \( S \) of genus \( g \) and an injection \( P := \{ p_1, \ldots, p_n \} \hookrightarrow S \) with \( n > 0 \).

2.1. The arc complex. Let \( \mathcal{A} \) be the set of isotopy classes relative to \( P \) of unoriented loops or arcs embedded in \( S \) that intersect \( P \) exactly in the extremal point(s). The arc complex is the abstract simplicial complex \( A(S, P) \) whose \( k \)-simplices are subsets \( \alpha = \{ \alpha_0, \ldots, \alpha_k \} \) of \( \mathcal{A} \) that are representable by a system of \( k + 1 \) arcs and loops intersecting only in \( P \). We will denote its geometric realization by \( |A| \).

A simplex \( \alpha = \{ \alpha_0, \ldots, \alpha_k \} \) of \( A \) is called proper if its star is finite, or equivalently if \( S \setminus \bigcup_{i=0}^k \alpha_i \) is a disjoint union of open disks, each one containing at most one point of \( P \). The subset \( A_\infty \subset A \) of improper simplices is a subcomplex; we denote \( A^\circ := A \setminus A_\infty \) the subset of proper ones and by \( |A^\circ| \) its “geometric realization” \( |A| \setminus |A_\infty| \).

We will associate a marked ribbon graph \( G_\alpha \) to every proper simplex \( \alpha \) in a natural way and a metric on \( G_\alpha \) to every internal point of \( |\alpha| \). Let us fix some notation first.

Definition 2.1. An (ordinary) ribbon graph \( G \) is a triple \( (X(G), \sigma_0, \sigma_1) \) such that \( X(G) \) is a nonempty finite set, \( \sigma_0 \) is a permutation of \( X(G) \) and \( \sigma_1 \) is a fixed-point-free involution of \( X(G) \). Let denote by \( X_i(G) \) the set of orbits in \( X(G) \) with respect to the action of \( \sigma_i \) for \( i = 0, 1 \).

![Figure 3. Geometric representation of a ribbon graph](image)

Remark that this definition is equivalent to the intuitive one given in terms of a graph plus a cyclic ordering of the half-edges incident on each vertex.
(see Fig. 3). In fact we shall regard \(X(G)\) as the set of oriented edges of \(G\), \(X_0(G)\) as the set of vertices and \(X_1(G)\) as the set of unoriented edges. So we can identify \(\sigma_0\) with the operator that sends an oriented edge outcoming from a vertex \(v\) to the following oriented edge outcoming from \(v\) with respect to a given cyclic order, and \(\sigma_1\) with the operator that simply reverses the orientation of the given oriented edge. Consequently, there is a natural bijection between connected components of the ribbon graph \(G\) and orbits in \(X(G)\) under the action of the subgroup \(\langle \sigma_0, \sigma_1 \rangle \subset \mathfrak{S}(X(G))\). Finally we can define \(\sigma_\infty\) requiring that \(\sigma_\infty \sigma_1 \sigma_0 = 1\), so that \(X_\infty(G)\) naturally corresponds to the set of holes of \(G\) and \(\sigma_\infty\) rotates the edges that border each hole. To each ribbon graph \((X(G), \sigma_0, \sigma_1)\) we can associate a dual one \(G^* := (X(G), \sigma_\infty^{-1}, \sigma_1)\) such that \((G^*)^* = G\).

**Definition 2.2.** A \(P\)-marking of \(G\) is an injection \(x : P \hookrightarrow X_0(G) \cup X_\infty(G)\) such that \(X_\infty(G)\) is in the image of \(x\). A realization of the ribbon graph \(G\) into an oriented surface \(S'\) is a realization of the graph \(|G|\) together with an embedding \(|G| \hookrightarrow S'\) which is compatible with the cyclic ordering of the half-edges incident on every vertex of \(|G|\). A realization is proper if \(S' \setminus |G|\) is a disjoint union of disks and of pointed disks.

We call \((G, x)\) reduced if every unmarked vertex has valency greater than two. In what follows ribbon graphs are intended to be reduced.

To each proper simplex \(\alpha = \{\alpha_0, \ldots, \alpha_k\}\) we can associate a connected ribbon graph \(G^*_\alpha\) simply taking as \(X(G^*_\alpha)\) the set of oriented versions of \(\alpha_i\)'s, as \(\sigma_1\) the sense-reversing operator and making \(\sigma_0\) rotate edges outcoming from a point \(p\) counterclockwise with respect to the given orientation of \(S\). It is easy to see that \(G_\alpha := (G^*_\alpha)^*\) inherits a \(P\)-marking: we call it the “dual” ribbon graph associated to \(\alpha\).

Now we show that both \(G^*_\alpha\) and \(G_\alpha\) admit proper realizations \(|G^*_\alpha|\) and \(|G_\alpha|\) in \(S\), which are canonically defined up to isotopy. This canonicity depends on the fact that orientation-preserving embeddings of a disk into an oriented surface are isotopic.

For \(G^*_\alpha\) it is sufficient to choose explicit representatives for the arcs \(\alpha_0, \ldots, \alpha_k\) and to take them as edges of the ribbon graph. For \(G_\alpha\) one proceeds in the following way. As \(\alpha\) is a proper simplex, the surface \(S \setminus |G^*_\alpha|\) is a disjoint union of disks and of pointed disks; then, one chooses as vertices of \(|G_\alpha|\) one point in each unmarked disk and the marked point in each pointed disk. Then, for every \(\alpha_i\) one draws on \(S\) an edge which joins the vertices corresponding to the disks separated by \(\alpha_i\) and which intersects the explicit representative of \(\alpha_i\) transversely in one point. It is easy to see that this determines a proper realization of the \(P\)-marked graph \(G_\alpha\) in \((S, x)\), which is canonical up to isotopy.

**Remark.** Fix realizations of \(G_\alpha\) and \(G^*_\alpha\). Both determine a cellular decomposition of \(S\) and so a complex of cellular chains in a natural way: call \(C_\bullet(S)\)
and $C_i^\bullet(S)$ these complexes. The construction described above induces natural isomorphisms $C_i(S) \cong C^\bullet_{i-2}(S)$ for $i = 0, 1, 2$, and it is easy to see that they induce Poincaré duality in homology.

**Definition 2.3.** A metrized ribbon graph is a couple $(G, l)$ where $G$ is a ribbon graph and $l$ is a positive metric of total length 1 on $G$, i.e. a point of $\Delta^\infty_{X_1}(G)$.

Actually it is clear that a point $a$ of $\Delta^\bullet \subset |A^\circ|$ correspond to a positive metric on $G^\circ_a$ and so on $G_a$. Moreover, if $\lambda : |A| \to \Delta_P$ is the simplicial map that sends a vertex $\{\alpha\}$ of $|A|$ to the barycenter of the extremal points of the arc $\alpha$, then the restriction of $\lambda$ to a proper simplex is the circumference function of the associated ribbon graph, that is, it sends a metrized ribbon graph $(G, a)$ to the point whose $p$-th coordinate is half the perimeter of the $p$-marked hole (it is zero in the case that $p$ marks a vertex).

To each metrized ribbon graph $(G, a)$ we can canonically associate a Riemann surface obtained by gluing half-infinite strips

$$S(G, a) := \left( \bigcup_{e \in \Xi(G)} T_e \right) / \sim$$

where $T_e = [0, e(a)] \times [0, \infty] / [0, e(a)] \times \{\infty\}$ and $\sim$ is the equivalence relation generated by $T_e \ni (t, 0) \sim (e(a) - t, 0) \in T_{\sigma_1(e)}$ and $T_e \ni (e(a), s) \sim (0, s) \in T_{\sigma_{\infty}(e)}$. Call $\bar{T}_e$ the image of $T_e$ under the above identifications and $(G$ is $P$-marked) $\bar{T}_p$ the union of the $\bar{T}_e$’s for all $e \in x(p)$ and notice that the conformal structures on $\bar{T}_e \setminus (\{\infty\} \cup \{0\} \times \{0\} \cup \{e(a)\} \times \{0\}) \subset \mathbb{R}^2 \cong \mathbb{C}$ glue to give a conformal structure on $S(G, a)$ minus a finite set and that it induces a well-defined unique complex structure on the whole $S(G, a)$. It is clear that a $P$-marking on $G$ descends to a $P$-marking $x' : P \to S(G, a)$ and that $G$ has a natural proper realization in $(S(G, a), x')$. As $G$ is also properly realized in $(S, x)$ (canonically up to isotopy), this determines an isotopy class of diffeomorphisms $(S, P) \sim (S(G, a), x'(P))$ and a classifying map $\Psi : |A^\circ(S, P)| \to T_{S, P}$ to the Teichmüller space.

**Theorem 2.4** (Harer-Mumford-Thurston). The map

$$(\Psi, \lambda) : |A^\circ(S, P)| \sim T_{S, P} \times \Delta_P$$

is a $\Gamma_{S, P}$-equivariant homeomorphism. Hence the quotient

$$\Phi : |A^\circ(S, P)| / \Gamma_{S, P} \sim \mathcal{M}_{g, P} \times \Delta_P$$

is a homeomorphism too.

**Proof.** One can construct a tautological family of Riemann surfaces $C \to |A^\circ(S, P)|$ whose restriction over a simplex $\alpha$ is real-analytic. So $\Psi$ is continuous by the universal property of the Teichmüller space and $\Psi|_{\alpha}$ is real-analytic for every $\alpha$. 

COMBINATORIAL CLASSES ON $\overline{\mathcal{M}}_{g, n}$ ARE TAUTOLOGICAL 13
Next, we recall that $|A^\circ(S,P)|$ can be given a structure of differentiable manifold compatible with the piecewise linear one (see [HM79]). Hence, if we prove that $(\Psi, \lambda)$ is bijective, then we can conclude that it is open and so a homeomorphism by invariance of domain.

To prove that $(\Psi, \lambda)$ is bijective, we notice that every $S(G,a)$ is canonically endowed with a meromorphic quadratic differential $\beta$ which restricts to $(dz)^2$ on each $T_\epsilon \subset \mathbb{C}$. This differential has three interesting properties (among others):

1. it is holomorphic in $S(G,a) \setminus x'(P)$ and almost all its horizontal trajectories (namely, those defined by $\text{Arg}(\beta) = 0$) are closed
2. for every $p \in P$: if $\lambda_p(a) > 0$, then $\beta$ has a double pole on $x'(p)$ with quadratic residue $-\left(\frac{\lambda_p(a)}{\pi}\right)^2$; if $\lambda_p(a) = 0$, then $x'(p)$ lies either a simple pole of $\beta$ or on a critical trajectory or is a zero of $\beta$
3. the zeroes of $\beta$ and the marked points $\{x'(p) \mid \lambda_p(a) = 0\}$ are the vertices of $|G_a| \subset S(G,a)$, the horizontal trajectories between these points (i.e. the critical trajectories) are the edges of $|G_a|$; hence the critical graph $\text{Crit}(\beta)$ of $\beta$ coincides with $|G_a|$.

Now we invoke the following celebrated result.

**Theorem 2.5** (Jenkins-Strebel, [Jen57] [Str67]). Let $\tilde{S}$ be a compact Riemann surface and $\tilde{x} : P \hookrightarrow \tilde{S}$ a nonempty subset such that $\chi(\tilde{S} \setminus \tilde{x}(P)) < 0$. Then, for every nonzero function $\tilde{h} : P \to \mathbb{R}_{\geq 0}$, there exists a unique meromorphic quadratic differential $\beta(\tilde{S}, P, \tilde{h})$ on $\tilde{S}$ with the following properties:

1. $\beta(\tilde{S}, P, \tilde{h})$ is holomorphic in $\tilde{S} \setminus \tilde{x}(P)$ and it has almost all closed horizontal trajectories (and so at most double poles)
2. every closed trajectory of $\beta(\tilde{S}, P, \tilde{h})$ is isotopic inside $\tilde{S} \setminus \tilde{x}(P)$ to a simple loop winding around the point $\tilde{x}(p)$ for some $p \in P \setminus \tilde{h}^{-1}(0)$
3. for every $p \in P \setminus \tilde{h}^{-1}(0)$, the differential $\beta(\tilde{S}, P, \tilde{h})$ has a double pole in $\tilde{x}(p)$ with quadratic residue $-\left(\frac{\tilde{h}(p)}{\pi}\right)^2$
4. for every $p \in \tilde{h}^{-1}(0)$, the point $\tilde{x}(p)$ is contained inside the critical graph of $\beta(\tilde{S}, P, \tilde{h})$ (and so $\tilde{x}(p)$ is at worst a simple pole).

A consequence of the previous theorem is that the critical graph of $\beta(\tilde{S}, P, \tilde{h})$ is a $P$-marked ribbon graph, properly embedded in $(\tilde{S}, \tilde{x})$. Furthermore it inherits a metric from the quadratic differential. Hence, we have produced a well-defined map

$$\mathcal{T}_{\tilde{S}, P} \times \Delta_P \quad \rightarrow \quad |A^\circ(S,P)|$$

$$([f : (S,P) \rightarrow (\tilde{S}, \tilde{x})], h) \quad \mapsto \quad \text{Crit}(\beta(\tilde{S}, P, \tilde{h}))$$

and one can see that it is the (set-theoretical) inverse of $(\Psi, \lambda)$. Hence $(\Psi, \lambda)$ is bijective and so a homeomorphism. \hfill \Box

**2.2. More on the arc complex.** We have just seen that there is a correspondence between points belonging to proper simplices of $|A(S,P)|$ and
COMBINATORIAL CLASSES ON $\overline{\mathcal{M}}_{g,n}$ ARE TAUTOLOGICAL

$P$-marked Riemann surfaces $\tilde{S}$ of genus $g$ together with an oriented diffeomorphism $f : S \sim \rightarrow \tilde{S}$ and a perimeter length $2l$, with $l \in \Delta_P$.

Now we recall how to describe points of $|A_\infty(S,P)| \subset |A(S,P)|$. This has already been done in [BE88] and [Pen96] in the hyperbolic setting and it can be adapted to the conformal case with minor modifications.

Keep the notation as in the previous subsection and fix an improper simplex $\alpha = \{\alpha_0, \ldots, \alpha_k\}$ of the arc complex $A(S,P)$. As before, $\alpha$ determines a (possibly disconnected) ribbon graph $G_\alpha^* = (X(G_\alpha^*), \sigma_0, \sigma_1)$ with a realization in $S$, but in this case the realization is not proper and so it does not determine a cellular structure in a natural way. The fact is that some components of $S \setminus |G_\alpha^*|$ are not disks or pointed disks but may have positive genus or may contain many marked points, thus no explicit link with Poincaré duality is any longer possible.

Nevertheless, we can find an open subsurface $N \subset S$ (up to isotopy) containing $|G_\alpha^*|$ such that $\partial N$ is a disjoint union of circles and $N \setminus |G_\alpha^*|$ is a collection of disks, pointed disks and cylinders that touch the boundary $\partial N$. More concretely, $N$ is obtained as the union of a fattening of $|G_\alpha^*|$ inside $S$ and of those components of $S \setminus |G_\alpha^*|$ that are disks or pointed disks; thus, $N$ can well be disconnected (for instance, see Fig. 4).

If $N$ is not the whole $S$, then $N$ is not compact. Call $\tilde{N}$ the unique compactification of $N$ to a surface obtained by adding a finite set $Q$ of “special points”, and notice that $G_\alpha^*$ has a canonical proper realization in $\tilde{N}$.

Now we can construct the “dual” ribbon graph $G_\alpha = (G_\alpha^*)^*$ by simply setting $G_\alpha := (X(G_\alpha^*), \sigma_\infty^{-1}, \sigma_1)$ as before. Notice that the holes of $G_\alpha$ are naturally marked by some elements of $P$ and that $Q$ marks some vertices in such a way that $G_\alpha$ admits a canonical realization in $\tilde{N}$ up to isotopy which is compatible with the markings (Fig. 5).

As a consequence, for every point $a \in \alpha$ we can build a Riemann surface $S(G_\alpha, a)$ as explained before, which comes endowed with an isotopy class of oriented diffeomorphisms $\tilde{N} \sim \rightarrow S(G_\alpha, a)$ and a Jenkins-Strebel differential, whose critical graph realizes $G_\alpha$.

The complement $N^c := S \setminus N$ is just a topological subsurface and it cannot be given a complex structure in a natural way. Hence, by means of Theorem 2.5 applied to $N$ componentwise, a point $a \in |A(S,P)|$ corresponds to an equivalence class of couples $(N, l)$, where

- $N \subset S$ is a nonempty open subsurface with complex structure, such that $\partial N$ consists of disjoint circles, and $l$ is a point of $\Delta_P$
- every connected component $N_i$ of $N$ contains at least one point $p$ of $P$ such that $l_p > 0$ and the Euler characteristic of $N_i \setminus P$ is negative
- no connected component of the complement $N^c$ is a disk or a pointed disk and $l_p = 0$ for every $p \in P \cap N^c$
Figure 4. An arc system corresponding to an improper simplex

Figure 5. Surface $\hat{N} = \hat{N}_1 \cup \hat{N}_2$ with a proper realization of $G_\alpha$

and two such couples $(N_1, l_1)$ and $(N_2, l_2)$ are to be considered equivalent if $l_1 = l_2$ and there is a biholomorphism $N_1 \sim N_2$ such that the inclusion $N_1 \hookrightarrow S$ and the composition $N_1 \sim N_2 \hookrightarrow S$ are isotopic relatively to the markings.

Figure 6. Dual graph of $(N, l)$ as in Figures 4 and 5

As a consequence, we can define a map

$$\overline{\Phi} : \{A(S, P)\}/\Gamma_{S,P} \longrightarrow \overline{M}_{g,P}$$

in the following way. Pick a point $a \in [A(S, P)]$ and consider the associated $N \subset S$. Then consider the surface $\overline{S}$ obtained from $S$ collapsing every circle of $\partial N$ to a point (Fig. 7). Moreover the positive components of $\overline{S}$
COMBINATORIAL CLASSES ON $\overline{M}_{g,n}$ ARE TAUROLOGICAL

(which correspond to the connected components of $\hat{N}$) are given a complex structure thanks to the diffeomorphism $S(G_\alpha, a) \cong \hat{N}$. Hence, we can set $\overline{\Phi}(a) := [S, \lambda(a)]$. It is easy to see that $\overline{\Phi}$ is well-defined and bijective. One can also prove that $\overline{\Phi}$ is continuous (see [Loo95] and the Appendix), and so it is a homeomorphism.

Remark. Unfortunately, the arc complex does not give a cellularization of the Deligne-Mumford compactification of $M_{g,P}$. On the contrary, we have just seen that there is a proper surjective map

$$\overline{\mathcal{M}}_{g,P} \times \Delta_P \to |A(S, P)|/\Gamma_{S,P}$$

which is in fact a quotient. In the Appendix, we sketch the construction of Looijenga’s modification of the arc complex $\hat{A}(S, P)$ (see [Loo95]) which “nearly” does the job.

2.3. The ribbon graph complex. Here we introduce the second complex we are interested in, for which we follow Kontsevich [Kon92]. The point of view is reversed: the central object is the ribbon graph and no longer the arc system (a point of view which was already present in [Pen88]).

Form the category $\mathcal{RG}_{g,P}$ of $P$-marked ribbon graphs of genus $g$ as follows. Its objects are the ribbon graphs $G_\alpha$ with $\alpha$ in $A^c(S, P)$, and its morphisms are compositions of isomorphisms of pointed ribbon graphs and contractions of one edge. Denote by $\mathcal{M}$ (resp. $\overline{\mathcal{M}}$) the functor $\mathcal{RG}_{g,P} \to (\text{Top. spaces})$ that associates $|\alpha| \cap |A^c| \times \mathbb{R}_+$ (resp. $|\alpha| \times \mathbb{R}_+$) to every $G_\alpha$ and by $\mathcal{M}_{g,P}^{\text{comb}}$ (resp. $\overline{\mathcal{M}}_{g,P}^{\text{comb}}$) its limit functor. Remark that both functors are represented by orbicellular complexes and that $\mathcal{M}_{g,P}^{\text{comb}} \subset \overline{\mathcal{M}}_{g,P}^{\text{comb}}$ embeds as a dense open subspace. Moreover we can define a circumference function $\tilde{\lambda}: \overline{\mathcal{M}}_{g,P}^{\text{comb}} \to \mathbb{R}_{\geq 0} \setminus \{0\}$ as in the case of the arc complex.

Remark. Notice that our definition of $\mathcal{M}_{g,P}^{\text{comb}}$ and $\overline{\mathcal{M}}_{g,P}^{\text{comb}}$ slightly differs from that of Kontsevich. In fact, we allow some holes to have perimeter zero.
(i.e. we admit marked vertices) while Kontsevich does not. Briefly, Kontsevich’s spaces are obtained from ours by intersecting \( \mathcal{M}_{g.P}^{\text{comb}} \) and \( \overline{\mathcal{M}}_{g.P}^{\text{comb}} \) with \( \lambda^{-1}(\mathbb{R}_+^P) \).

Observe that the points of \( \overline{\mathcal{M}}_{g.P}^{\text{comb}} \) correspond to the following data:

- a connected graph \( \gamma \) (the “dual graph of the pointed surface”) with vertices \( V \) labelled by pairs \((g_v, P_v)\) such that \( \sqcup_{v \in V} P_v = P \) and \( \sum_{v \in V} g_v + \dim H^1(|\gamma|) = g \) (where \( |\gamma| \) is a topological realization of \( \gamma \))
- a subset \( V_+ \subset V \) of vertices of \( \gamma \) (the “positive vertices of the dual graph”)
- for every vertex \( v \in V_+ \) an ordinary \( P_v \cup Q_v \)-marked ribbon graph \((G_v, x_v)\) of genus \( g_v \) with positive metric (possibly of total length different from 1) such that \( Q_v \) marks only vertices of \( G_v \), where \( Q_v \) bijectively correspond to the set of half-edges of \( \gamma \) incident on \( v \).

We require moreover that no edge of \( \gamma \) joins two nonpositive vertices (i.e. that the \( \gamma \) is reduced).

It is easy to see that the natural map
\[
F : \overline{\mathcal{M}}_{g.P}^{\text{comb}} \xrightarrow{\sim} \overline{\mathcal{M}}_{g,P}^{\Delta} \times \mathbb{R}_+^P
\]
is bijective and proper (see [Kon92]). One can prove that \( F \) is also continuous (see [Loo95] and the Appendix), so \( F \) is a homeomorphism.

We summarize the preceding observations in the following commutative diagram

\[
\begin{array}{ccc}
\mathcal{M}_{g.P} \times (\mathbb{R}_+^P \setminus \{0\}) & \xrightarrow{\phi} & \overline{\mathcal{M}}_{g,P}^{\Delta} \times \mathbb{R}_+^P \\
F & \cong & F \\
\xi & \cong & \xi
\end{array}
\]

and we recall that \( \xi \) is the map that collapses nonpositive components so that its fibers are isomorphic to products of smaller moduli spaces. Notice that the homeomorphism \( F^{-1} \Phi \) is induced by the \( \Gamma_{S,P} \)-equivariant map
\[
|A(S, P)|/\Gamma_{S,P} \times \mathbb{R}_+^P \xrightarrow{\Phi} |A(S, P)|/\Gamma_{S,P} \times \mathbb{R}_+ \\
\cong \mathcal{M}_{g.P}^{\text{comb}} \xrightarrow{\cong} \overline{\mathcal{M}}_{g,P}^{\text{comb}}
\]
that sends a point \( a \in |A(S, P)| \) corresponding to \((N, l)\) to the point of \( \overline{\mathcal{M}}_{g,P}^{\text{comb}} \) associated to \((\gamma_{S,l}, G_a)\), where \( \gamma_{S,l} \) is the (reduced) dual graph of
The moduli spaces \( \mathcal{M}_{g,P} \) of complex projective stable curves have also the structure of smooth proper Deligne-Mumford stacks over \( \mathbb{C} \), so it is possible to define the Chow intersection ring with rational coefficients \( CH^\ast(\mathcal{M}_{g,P})_\mathbb{Q} \) (as the \( \mathcal{M}_{g,P} \) are global quotients of smooth projective varieties by finite groups it is also possible to define integral Chow rings and \( CH^\ast(\mathcal{M}_{g,P})_\mathbb{Z} = CH^\ast(\mathcal{M}_{g,P})_\mathbb{Q} \otimes \mathbb{Z} \)).

There are three kinds of natural maps:

3. Tautological classes

Let \( g,n \) be nonnegative integers such that \( 2g - 2 + n > 0 \) and let \( P := \{ p_1, \ldots, p_b \} \). The moduli spaces \( \mathcal{M}_{g,P} \) of complex projective stable curves have also the structure of smooth proper Deligne-Mumford stacks over \( \mathbb{C} \), so it is possible to define the Chow intersection ring with rational coefficients \( CH^\ast(\mathcal{M}_{g,P})_\mathbb{Q} \) (as the \( \mathcal{M}_{g,P} \) are global quotients of smooth projective varieties by finite groups it is also possible to define integral Chow rings and \( CH^\ast(\mathcal{M}_{g,P})_\mathbb{Z} = CH^\ast(\mathcal{M}_{g,P})_\mathbb{Q} \otimes \mathbb{Z} \)).
(1) the proper and flat map \( \pi_q : \overline{M}_{g,P \cup \{q\}} \to \overline{M}_{g,P} \) that forgets the point \( q \) and stabilizes the curve (i.e. contracts two-pointed spheres), which is isomorphic to the universal family and so is endowed with natural sections \( \vartheta_{0,\{p_i,q\}} : \overline{M}_{g,P} \to \overline{M}_{g,P \cup \{q\}} \) for all \( p_i \in P \).

(2) the proper map \( \vartheta_{irr} : \overline{M}_{g-1,P \cup \{p',p''\}} \to \overline{M}_{g,P} \) (defined for \( g > 0 \)) that glues \( p' \) and \( p'' \) together.

(3) the proper map \( \vartheta_{g',I} : \overline{M}_{g',I \cup \{p'\}} \times \overline{M}_{g-g',I \cup \{p''\}} \to \overline{M}_{g,P} \) (defined for every \( 0 \leq g' \leq g \) and \( I \subseteq P \) such that the spaces involved are nonempty) that takes two curves and glues them together identifying \( p' \) and \( p'' \).

Call \( \delta_{irr} \subseteq \overline{M}_{g,P} \) and \( \delta_{g',I} \subseteq \overline{M}_{g,P} \) the divisors supported on the image of \( \vartheta_{irr} \) and \( \vartheta_{g',I} \). When no confusion can occur, we will denote by the same symbol the divisors and the associated classes in the Chow ring or in homology.

If \( \omega_{\pi_q} \) denote the relative dualizing sheaf and \( L_{p_i} := \vartheta_{0,\{p_i,q\}}^* (\omega_{\pi_q}) \), then define the Miller classes as

\[
\psi_{p_i} := c_1(L_{p_i}) \in CH^1(\overline{M}_{g,P})_{\mathbb{Q}}
\]

and the modified (by Arbarello-Cornalba) Mumford-Morita classes as

\[
\kappa_j := (\pi_q)_*(c_1(\omega_{\pi_q} (\sum_i \delta_{0,\{p_i,q\}}))^{j+1}) \in CH^j(\overline{M}_{g,P})_{\mathbb{Q}}.
\]

When there is no risk of ambiguity, we will denote in the same way the line bundles \( L \) and the classes \( \psi \) and \( \kappa \) belonging to different \( \overline{M}_{g,P} \)'s. Because of the natural definition of \( \kappa \) and \( \psi \) classes, the subring \( RH^* (\overline{M}_{g,P}) \) of \( CH^* (\overline{M}_{g,P})_{\mathbb{Q}} \) they generate is called tautological ring of \( \overline{M}_{g,P} \). Its image \( RH^* (\overline{M}_{g,P}) \) through the cycle class map is called cohomology tautological ring.

The system of tautological rings \( (RH^*(\overline{M}_{g,P}) \subseteq CH^*(\overline{M}_{g,P})_{\mathbb{Q}}) \) is minimal system of subrings that contain the classes \( \kappa \) and \( \psi \) which is closed under the push-forward maps \( \pi_* \), \( (\vartheta_{irr})_* \) and \( (\vartheta_{g',I})_* \). The definition is the same for the rational cohomology.

The psi classes and the kappa classes are related in a very nice way. In fact

\[
(\pi_q)_*(\psi_{p_1}^{r_1} \cdots \psi_{p_n}^{r_n}) = \sum_{i \mid r_i > 0} \psi_{p_1}^{r_1} \cdots \psi_{p_i}^{r_i-1} \cdots \psi_{p_n}^{r_n}
\]

\[
(\pi_q)_*(\psi_{p_1}^{r_1} \cdots \psi_{p_n}^{r_n} \psi_{q}^{b+1}) = \psi_{p_1}^{r_1} \cdots \psi_{p_n}^{r_n} \kappa_b
\]

where the first one is the so-called string equation and the second one for \( b = 0 \) is the dilaton equation.

In [AC96] Arbarello and Cornalba noticed that the previous formulas, together with the relation

\[
\pi_q^*(\kappa_b) = \kappa_b + \psi_q^b
\]
and a repeated use of the push-pull formula, make it possible to compute the push-forward of any polynomial in the \( \psi \)'s through the forgetful maps.

The following explicit formula for maps that forget more than one point was found by Faber. Let \( Q := \{ q_1, \ldots, q_m \} \) and let \( \pi_Q : \overline{M}_{g,P,q} \to \overline{M}_{g,P} \) be the forgetful map. Then
\[
(\pi_Q)_*(\psi_{p_1}^{r_1} \cdots \psi_{p_n}^{r_n} \psi_{q_1}^{b_1} \cdots \psi_{q_m}^{b_m}) = \psi_{q_1}^{r_1} \cdots \psi_{q_m}^{r_m} K_{b_1 \cdots b_m}
\]
where \( K_{b_1 \cdots b_m} = \sum_{\sigma \in S_m} \kappa_b(\sigma) \) and \( \kappa_b(\sigma) \) is defined in the following way. If \( \gamma = (c_1, \ldots, c_l) \) is a cycle, then \( b(\gamma) := \sum_{j=1}^{l} b_{c_j} \). If \( \sigma = \gamma_1 \cdots \gamma_\nu \) is the decomposition in disjoint cycles (including 1-cycles), then we define \( k_b(\gamma) := \prod_{i=1}^{\nu} k_b(\gamma_i) \).

Another property we will use is the following. Consider the map
\[
\vartheta_{0,\{p_i,q\}} : \overline{M}_{g,P} \to \overline{M}_{g,P \cup \{q\}}.
\]
One can easily check that the line bundle \( \vartheta_{0,\{p_i,q\}}^*(L_q) \) is trivial, so that \( \vartheta_{0,\{p_i,q\}}^*(\psi_{q}) = 0 \) in \( H^2(\overline{M}_{g,P}) \). If we call \( D_q \) the (disjoint) union \( \cup_i \delta_{0,\{p_i,q\}} \), then the exact sequence of the couple
\[
0 = H^1(D_q) \to H^2(\overline{M}_{g,P \cup \{q\}}) = H^2(\overline{M}_{g,P \cup \{q\}}) \to H^2(D_q) \to H^2(D_q)
\]
shows that \( \psi_q \) lifts to a class in \( H^2(\overline{M}_{g,P \cup \{q\}}, D_q) \).

Similarly, consider the following situation. Let \( Q = \{ q_1, \ldots, q_m \} \) and for every \( Q' \subset Q \) define \( D_{Q',P} \subset \overline{M}_{g,P \cup Q} \) to be the union of all divisors of the type \( \delta_{0,\{q_1, \ldots, q_{j_h}, p_i\}} \) with \( p_i \in P \) and \( \{ q_{j_1}, \ldots, q_{j_h} \} \subset Q' \). Then, for every \( b_1, \ldots, b_m \geq 0 \), the class \( \psi_{q_1}^{b_1} \cdots \psi_{q_m}^{b_m} \) admits a lift to \( H^*(\overline{M}_{g,P \cup Q}, D_{Q',P}) \). In fact, as \( \pi_{q_i}^*(\psi_{p_i}) = \psi_{p_i} - \delta_{0,\{p_i,q_i\}} \), the class we are interested in coincides with
\[
\pi_{q_{j_1}, \ldots, q_2}^*(\psi_{q_1}^{b_1}) \cdots \pi_{q_{j_1}, \ldots, q_1}^*(\psi_{q_2}^{b_2}) \cdots \pi_{q_{j_1}, \ldots, q_{j_h}}^*(\psi_{q_{j_h}}^{b_{j_h} - 1}) \cdot \psi_{q_{j_h}+1}^{b_{j_h}}
\]
which lies in the image of the homomorphism
\[
\bigotimes_{j=1}^{m} H^*(\overline{M}_{g,P \cup \{q_{j_1}, \ldots, q_j\}}, D_{\{q_j\},P}) \to H^*(\overline{M}_{g,P \cup Q}, D_{Q',P})
\]
which pulls classes back via appropriate forgetful morphisms and then multiplies them together.

We refer to [KMZ96] for some remarks on Faber’s formula, its inversion and for other useful formulas on Weil-Petersson volumes.

Moreover, we refer [AC96] for a proof of the above relations between \( \kappa \) classes and \( \psi \) classes, and to [Fab99] for a conjectural description of the tautological rings.

4. Combinatorial classes

Fix a compact oriented surface \( S \) of genus \( g \) and a nonempty subset \( P = \{ p_1, \ldots, p_n \} \) of \( n \) distinct points of \( S \) such that \( 2g - 2 + n > 0 \).
Let $m_\ast = (m_{-1}, m_0, m_1, \ldots)$ be a sequence of nonnegative integers such that
\[ \sum_{i \geq -1} (2i + 1)m_i = 4g - 4 + 2n \]
and define $(m_\ast)! := \prod_{i \geq -1} m_i!$ and $r := \sum_{i \geq -1} i m_i$.

**Warning.** Even if one could still define combinatorial classes with $m_{-1} > 0$, much more care is needed to handle them. Moreover, in this case the argument of Lemma 8.5 would not be sufficient to complete the proof of Theorem B. Therefore we assume $m_{-1} = 0$ in what follows.

Reasoning as in Section 2.3, it is possible to construct an orbispace $\overline{\mathcal{M}}_{m_\ast, P}^{\text{comb}}$ whose cells of maximal dimension are indexed by isomorphism classes of ordinary ribbon graphs that have exactly $m_i$ vertices of valency $2i + 3$. Analogously it is possible to define an arc complex $A(S, P)_{m_\ast}$ as the smallest subcomplex of $A(S, P)$ that contains all simplices $\alpha$ such that $G_\alpha$ is an ordinary ribbon graph with exactly $m_i$ vertices of valency $2i + 3$. Notice that both these complexes are acted on by $\Gamma_{S, P}$ and so is $A^\circ(S, P)_{m_\ast} := A(S, P)_{m_\ast} \cap A^\circ(S, P)$. Thus, the following diagram is obviously commutative.

\[
\begin{array}{ccc}
(A^\circ(S, P)_{m_\ast}) \times \mathbb{R}_+ & \xrightarrow{\cong} & \mathcal{M}_{m_\ast, P}^{\text{comb}} \\
\downarrow & \Downarrow & \downarrow \\
(A(S, P)_{m_\ast}) \times \mathbb{R}_+ & \xrightarrow{\cong} & \overline{\mathcal{M}}_{m_\ast, P}^{\text{comb}}
\end{array}
\]

In what follows, we will naturally identify arc complexes with combinatorial moduli spaces.

**Remark.** In the case $m_{-1} > 0$ it is still possible to define $A(S, P)_{m_\ast}$ (and $A^\circ(S, P)_{m_\ast}$) as a subcomplex of an extended arc complex $\tilde{A}(S, P)$, obtained adding to $A$ contractible loops (i.e. unmarked tails in the corresponding ribbon graph picture). However $A(S, P)_{m_\ast}$ is no longer a subcomplex of $A(S, P)$, so we can only define $\mathcal{M}_{m_\ast, P}^{\text{comb}} \to \mathcal{M}_{g, P} \times (\mathbb{R}^P_{\geq 0} \setminus \{0\})$ as a classifying map by constructing a family of Riemann surfaces over $\mathcal{M}_{m_\ast, P}^{\text{comb}}$.

Now consider the following commutative diagram.

\[
\begin{array}{ccc}
\mathcal{M}_{m_\ast, P}^{\text{comb}} & \xrightarrow{\cong} & \mathcal{M}_{g, P} \times (\mathbb{R}^P_{\geq 0} \setminus \{0\}) \\
\downarrow & \Downarrow & \downarrow \\
\overline{\mathcal{M}}_{m_\ast, P}^{\text{comb}} & \xrightarrow{\cong} & \overline{\mathcal{M}}_{g, P} \times (\mathbb{R}^P_{\geq 0} \setminus \{0\})
\end{array}
\]

For every $l \in \mathbb{R}^P_{\geq 0} \setminus \{0\}$ call $\overline{\mathcal{M}}_{g, P}^{\text{comb}}(l)$ the slice $\overline{\lambda}^{-1}(l) \subset \overline{\mathcal{M}}_{g, P}^{\text{comb}}$. In the same way we can define $\overline{\mathcal{M}}_{m_\ast, P}(l)$ and the restriction
\[
\xi_l : \overline{\mathcal{M}}_{g, P} \to \overline{\mathcal{M}}_{g, P}^{\text{comb}}(l)
\]
of $\xi$. Notice that the dimensions of the slices are the expected ones, because in every cell they are described by a system of $n$ independent linear equations.

**Lemma 4.1** ([Kon92]). Fix $p \in P$ and $l \in \mathbb{R}^P_{\geq 0}$ such that $l_p > 0$. Then, on every simplex $\alpha \in \overline{M}_{g,P}^c(l)$, define

$$\overline{\omega}_l|_\alpha := \sum_{1 \leq s < t \leq k} d \left( \frac{e_s(a)}{2l_p} \right) \wedge d \left( \frac{e_t(a)}{2l_p} \right)$$

where $x(p)$ is a hole with cyclically ordered sides $(e_1, \ldots, e_k)$. These 2-forms glue to give a piecewise-linear 2-form $\overline{\omega}$ on $\overline{M}_{g,P}^c(l)$ and the class $\xi^*_l[\overline{\omega}_l]$ pulls back to $\psi_p$ in $H^2(\overline{M}_{g,P})$.

**Lemma 4.2** ([Kon92]). For every $l \in \mathbb{R}^P_{\geq 0} \setminus \{0\}$ the restriction of $\overline{\Omega} := \sum_{\alpha \in P} \overline{\omega}_l|_\alpha$ to $\overline{M}_{g,P}^c(l)$ is a nondegenerate symplectic form, so $\overline{\Omega}$ defines an orientation on $\overline{M}_{g,P}^c(l)$. Hence, $\overline{\Omega}^r \wedge \lambda^*d\nu|_{\mathbb{R}^P_+}$ is an orientation on $\overline{M}_{g,P}^c(\mathbb{R}^P_+)$.

**Lemma 4.3** ([Kon92]). With the given orientation $\overline{M}_{g,P}^c(l)$ is a cycle for all $l \in \mathbb{R}^P_{\geq 0} \setminus \{0\}$ and $\overline{M}_{g,P}^c(\mathbb{R}^P_+)$ is a cycle with noncompact support.

Notice that the space $\overline{M}_{g,P}^c$ reduces to $\overline{M}_{g,P}^c$ when restricted to the locus of ordinary ribbon graphs, and it coincides with the closure of $\overline{M}_{g,P}^c$ in $\overline{M}_{g,P}$.

Define the combinatorial classes $W_{g,n}(l) := [\overline{M}_{g,P}^c(l)]$ and $\overline{W}_{g,n}(l) := [\overline{M}_{g,P}^c(l)]$, and observe that Künneth formula and $H^*_{BM}(\mathbb{R}^P_+) \cong \mathbb{Q}[-n]$ give the following isomorphism

$$H^*_{BM}(\overline{M}_{g,P}^c(\mathbb{R}^P_+)) \cong H^*_{BM}(\overline{M}_{g,P}^c(l))$$

and analogously

$$H^*_{BM}(\overline{M}_{g,P}^c(\mathbb{R}^P_+)) \cong H^*_{BM}(\overline{M}_{g,P}^c(l))$$

for every $l \in \mathbb{R}^P_+$, naturally with respect the inclusion $\overline{M}_{g,P}^c \hookrightarrow \overline{M}_{g,P}^c$. Therefore, we will write $W_{g,n}(l)$ and $\overline{W}_{g,n}(l)$ instead of $W_{g,n}(l)$ and $\overline{W}_{g,n}(l)$ for the homology classes they define on $M_{g,P}(l) \cong M_{g,P}$ and $\overline{M}_{g,P}^c(l)$ respectively, for any $l \in \mathbb{R}^P_+$. Moreover, we will also identify $W_{g,n}$ with its Poincaré dual in $H^{2r}(M_{g,P})$. 
It is possible to define a slight generalization of the previous classes, prescribing that some markings hit vertices with assigned valency.

Given a finite set $Q = \{q_1, \ldots, q_h\}$ and a map $\rho : Q \to \mathbb{Z}_{\geq -1}$, we define $m_\rho^h = (m_\rho^{h-1}, m_\rho^0, \ldots) = (|\rho^{-1}(i)|)$. Consider now an $m_\ast$ and a $\rho$ such that $m_\rho^{h-1} = m_{\ast-1}$, $m_\rho^h \leq m_\ast$ and $\sum_{i \geq -1} (2i + 1) m_i = 4g - 4 + 2|P|$, and call $\overline{\mathcal{M}}_{m_\ast, \rho, P}$ the subcomplex of $\overline{\mathcal{M}}_{m_\ast, P; Q}$ whose simplices of maximal dimension are ordinary ribbon graphs in which $q_j$ marks a vertex of valency $2\rho(q_j) + 3$ for every $j = 1, \ldots, h$. Then, denote by $\overline{W}_{m_\ast, \rho, P}$ its homology class inside some slice of $\overline{\mathcal{M}}_{g, P; Q}(\tilde{l})$ with $\tilde{l} \in \mathbb{R}_+ \times \{0\}^Q$ (as before the orientation is determined by $\sum_{p \in P} l^i_p \omega_p$). Define analogously $\overline{\mathcal{M}}^\text{comb}_{m_\ast, \rho, P} = \overline{\mathcal{M}}_{m_\ast, \rho, P} \cap \overline{\mathcal{M}}^\text{comb}_{g, P; Q}$ and let $\overline{\mathcal{W}}_{m_\ast, \rho, P}$ be its Borel-Moore homology class inside the same slice of $\overline{\mathcal{M}}^\text{comb}_{g, P; Q}$.

Notice that the combinatorial classes $\overline{W}_{m_\ast, P}$ are not defined on the Deligne-Mumford compactification but only on the combinatorial compactification (analogously for $\overline{W}_{m_\ast, \rho, P}$). This last space is often singular, so we cannot use Poincaré duality in order to obtain a cohomology class to lift to the Deligne-Mumford compactification.

However the singular locus of $\overline{\mathcal{M}}^\text{comb}_{g, P}(l)$ is contained inside $\Sigma^\text{comb}_{g, P}(l)$. Thus, the following diagram

$$
\begin{array}{ccc}
H_{6g-6+2n-2r}(\overline{\mathcal{M}}^\text{comb}_{g, P}(l)) & \longrightarrow & H_{6g-6+2n-2r}(\overline{\mathcal{M}}^\text{comb}_{g, P}(l), \Sigma^\text{comb}_{g, P}(l)) \\
& \parallel \downarrow & \\
H_{6g-6+2n-2r}(\overline{\mathcal{M}}_{g, P}(l), \Sigma_{g, P}(l))
\end{array}
$$

shows that we can lift the combinatorial classes on the Deligne-Mumford compactification up to some ambiguities.

**Remark.** One can try solve these ambiguities using a different combinatorial compactification $\mathcal{M}^\text{comb}_{g, P}$, which maps to $\overline{\mathcal{M}}_{g, P}$. Looijenga’s modification of the arc complex (see [Loo95]) offers a natural candidate, but it seems much more difficult to prove that the combinatorial chains are in fact cycles (see the Appendix).

As it is evident from the definition, the cycles $\overline{W}_{m_\ast, \rho, P}$ and $\overline{W}_{m_\ast, P}$ are closely related. It seems that one can obtain a multiple of $\overline{W}_{m_\ast, P}$ from $\overline{W}_{m_\ast, \rho, P}$ by simply “forgetting” the $Q$-marking, so that one would like to deduce a kind of push-forward formula for combinatorial classes which looks like

$$
\left(\pi_Q\right)_*(\overline{W}_{m_\ast, \rho, P}) = N(m_\ast, \rho) \overline{W}_{m_\ast, P}
$$

where the integer coefficient $N(m_\ast, \rho)$ counts in how many ways one can obtain a top-dimensional cell of $\overline{W}_{m_\ast, \rho, P}$ by $Q$-marking vertices of a fixed top-dimensional cell of $\overline{W}_{m_\ast, P}$.
In general, $\pi_q(\Sigma^l_{g,P})$ is not contained inside $\Sigma_{g,P}$ or even in the boundary $\partial \mathcal{M}_{g,P}$. For instance, in the case $Q = \{q\}$, the image $\pi_q(\Sigma^q_{g,P})$ does not lie inside $\Sigma_{g,P}$, but $\pi_q(\Sigma^q_{g,P}) \setminus \Sigma_{g,P}$ contains the locus of surfaces with an unmarked three-noded sphere. Hence it has complex codimension three. Nevertheless, in this particular case, $\pi_q(\Sigma^q_{g,P})$ is contained inside $\partial \mathcal{M}_{g,P}$.

5. Shrinking map and combinatorial forgetful map

Before introducing some technical tools, we want to describe the basic ideas involved in the proof of Theorem A. The first observation is that $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\tilde{l})$ is homeomorphic to $\mathcal{M}_{g,P \cup \{q\}}$ for every $\tilde{l} \in \mathbb{R}_{\geq 0}^{P \cup \{q\}} \setminus \{0\}$. The second remark is that the differential form $\omega_q := \partial^q_{M}^{\text{comb}}$ lives on the slices $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\tilde{l})$ such that $\tilde{l}_q > 0$, while the generalized combinatorial class (which we will briefly denote by $W^{q}_{2r+3}$), defined prescribing that $q$ marks a vertex of valency (at least) $2r + 3$, lives on the slices that have $\tilde{l}_q = 0$.

Consequently, a deformation retraction $\mathcal{H}_0^q$ of $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}$ onto the slice defined by $\tilde{l}_q = 0$ would help us to compare $\omega_{q+1}^{r+1}$ and the combinatorial class $W^{q}_{2r+3}$ as functionals on the cohomology of $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\tilde{l})$.

However, the deformation retraction $\mathcal{H}_0^q$ we will construct does not preserve the locus of smooth curves, but it retracts $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}$ onto the slice $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\{\tilde{l} = 0\})$. In fact, $\mathcal{H}_0^q$ is defined sending all the edges bordering the $q$-th hole to zero (and it is defined only when $\tilde{l}_q$ is “small”, because we must avoid the situation in which $\mathcal{H}_0^q$ would squeeze another hole beside $q$). Thus, it shrinks a circular $q$-th hole (i.e. such that $T_q$ is a disk) to a $q$-marked vertex; while it produces a surface with a $q$-marked nonpositive component, if the topology of the $q$-th hole is more complicated. Anyway, if we subdivide the complex $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}$ into subcomplexes $\mathcal{Y}_*$ according to the topology of the $q$-th hole, then the restriction of $\mathcal{H}_0^q$ to each subcomplex becomes a simplicial fibration.

Finally, we consider a differential form $\eta$ on $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\{\tilde{l}_q = 0\})$ and we compare the integral of $\eta$ on $W^{q}_{2r+3}(\tilde{l})$ (the closure of $W^{q}_{2r+3}(\tilde{l})$) for an $\tilde{l}$ such that $\tilde{l}_q = 0$ with the integral of $\omega^{r+1}_q \wedge (\mathcal{H}_0^q)^* \eta$ on $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\tilde{l})$ for an $\tilde{l}$ such that $\tilde{l}_q > 0$. Here we notice that the restriction of the form $\omega^{r+1}_q \wedge (\mathcal{H}_0^q)^* \eta$ to $\mathcal{M}^{\text{comb}}_{g,P \cup \{q\}}(\tilde{l})$ has support on the top-dimensional simplices whose $q$-th hole has exactly $2r + 3$ distinct edges; then the integral of $\omega^{r+1}_q \wedge (\mathcal{H}_0^q)^* \eta$ is evaluated by calculating the integral of $\omega^{r+1}_q$ on the fibers of the restriction of $\mathcal{H}_0^q$ to $\mathcal{Y}_*$, for each subcomplex $\mathcal{Y}_*$. In the case of a circular $q$-th hole with $2r + 3$ edges, from this integration we obtain the coefficient $2^{r+1}(2r + 1)!$. 

COMBINATORIAL CLASSES ON $\mathcal{M}_{g,n}$ ARE TAUROLOGICAL 25
The analogous result for the ordinary combinatorial class $W_{2r+3}$ (supported on the smallest subcomplex containing all ribbon graphs with a $(2r + 3)$-valent vertex) and $\kappa_r$ is derived from the previous one by noticing that the forgetful morphism $\pi_q$ has a combinatorial analogue $\pi_q^{\text{comb}}$ on the combinatorial spaces (another little technical problem is due to the fact that $\pi_q^{\text{comb}}$ is not defined on the whole $\mathcal{M}_{g,P \cup \{q\}}^{\text{comb}}$, but this is also superable).

As a consequence, $(\pi_q)_*(\psi^{r+1}_q) = \kappa_r$ and $(\pi_q^{\text{comb}})_*$ sends $W_{2r+3}$ to $W_{2r+3}$. Hence we obtain our result for the kappa classes too.

As the shrinking map $H^q$ and the combinatorial forgetful map $\pi^{\text{comb}}_q$ play a main role, this section will deal with their definition and their properties.

Fix $g \geq 0$ and a nonempty set of markings $P = \{p_1, \ldots, p_n\}$ such that $2g - 2 + n > 0$ and define

$$C_{P,q} := \{ \tilde{l} \in \mathbb{R}^{P \cup \{q\}} \geq 0 | \tilde{l}_q < \tilde{l}_p \ \text{for all} \ p \in P\}.$$  

Denote by $\pi_q : \mathcal{M}_{g,P \cup \{q\}} \times C_{P,q} \rightarrow \mathcal{M}_{g,P} \times \mathbb{R}^+_P$ the map that forgets $q$ and the $q$-th coordinate. We can define $\pi_q^{\text{comb}}$ forcing the commutativity of the following diagram

$$
\begin{array}{ccc}
(\mathcal{M}_{g,P \cup \{q\}} \setminus D_q) \times C_{P,q} & \xrightarrow{\tilde{\xi}} & (\mathcal{M}_{g,P \cup \{q\}}^{\text{comb}} \setminus D_q^{\text{comb}}) (C_{P,q}) \\
\pi_q \downarrow & & \downarrow \pi_q^{\text{comb}} \\
\mathcal{M}_{g,P} \times \mathbb{R}^+_P & \xrightarrow{\xi} & \mathcal{M}_{g,P}^{\text{comb}} (\mathbb{R}^+_P)
\end{array}
$$

where $D_q = \bigcup_{p \in P} \delta_{0,(q,p)}$ and $D_q^{\text{comb}} = \tilde{\xi}(D_q)$. We remark that $\xi \pi_q$ does not factorize through $\tilde{\xi} : \mathcal{M}_{g,P \cup \{q\}} \times C_{P,q} \rightarrow \mathcal{M}_{g,P \cup \{q\}}^{\text{comb}} (C_{P,q})$. In fact pick a point $(S, \tilde{l})$ in $\mathcal{M}_{g,P \cup \{q\}} \times C_{P,q}$ such that $q$ and $p$ lie on a two-pointed component $S_1$ of $S$ of genus zero which has only one singular point and suppose that the adjacent component $S_2$ is nonpositive (see Fig. 8). Then $\xi(S, \tilde{l})$ does not “remember” the analytic type of $S_2$ but $\xi \pi_q(S, \tilde{l})$ does (if $\tilde{l}_p > 0$) because

![Figure 8](image-url)

**Figure 8.** $\pi_q^{\text{comb}}$ is not defined in this case
the $p$-marking now hits $S_2$ after forgetting $q$ and stabilizing. However this is the only bad case, so it sufficient to excise $D_q$ and $D_q^{\text{comb}}$.

**Remark.** The behaviour of the map $\pi_q^{\text{comb}}$ is really mysterious as we do not know in general how Jenkins-Strebel’s differential changes when we delete the marked point $q$ and consequently how the critical graph modifies. However, we know that if $q$ marks a vertex of valency at least two, then the new critical graph is obtained simply forgetting the marking. On the contrary, we get in troubles if we try to forget the $q$-marking and $q$ marks a univalent vertex. This explains why it is more difficult to deal with univalent vertices.

**Notation.** Call $\overline{\mathcal{Y}}_h \subset \overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}$ the closure of the locus of graphs where the $q$-marked hole has positive perimeter and consists exactly of $h$ distinct (unoriented) edges. Moreover, set $\overline{\mathcal{Y}} \supset \bigcup_{i \geq h} \mathcal{Y}_i$ and $\overline{\mathcal{Y}} \supset \bigcup_{i \leq h} \mathcal{Y}_i$.

Clearly, the topological boundary $\partial \overline{\mathcal{Y}} \geq h$ is contained inside $\overline{\mathcal{Y}} \leq h-1$. Moreover, $\overline{\mathcal{Y}} \supset 2(C_{P,q})$ is contained inside $\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}} \setminus D_q^{\text{comb}}(C_{P,q})$. In fact, taking perimeters in $C_{P,q}$ is essential to our purposes; a consequence of this choice is that $\overline{\mathcal{Y}}_1(C_{P,q})$ is a closed neighbourhood of $D_q^{\text{comb}}(C_{P,q})$ inside $\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(C_{P,q})$, which is false for $\overline{\mathcal{Y}}_1(\tilde{I})$ with $\tilde{I} \notin C_{P,q}$.

Now, since we will work with the differential form $\overline{\omega}_q$, which is defined only where $\tilde{I}_q > 0$, then we let the perimeters vary in the subset $C_{P,q}^+ := C_{P,q} \cap \{ \tilde{I}_q > 0 \}$ only.

Remark that $\overline{\omega}_q|_{\overline{\mathcal{Y}}_1(\tilde{I})} = 0$ with $\tilde{I} \in C_{P,q}^+$, because the hole $q$ does not contain enough edges. Thus, if $\eta$ is a piecewise-linear differential form on $\overline{\mathcal{Y}} \supset (C_{P,q}^+) \subset \overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}$ then $\eta \wedge \omega_q^{r+1}$ regularly extends by zero to the whole $\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(C_{P,q})$ for every $r \geq 0$.

The previous observations and the commutativity of the following diagram

$$
\begin{array}{ccc}
\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(C_{P,q}) \setminus D_q^{\text{comb}}(C_{P,q}) & \xrightarrow{\xi} & \overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(C_{P,q}^+) \setminus D_q^{\text{comb}}(C_{P,q}^+) \\
\pi_q \downarrow & & \pi_q^{\text{comb}} \\
\overline{\mathcal{M}}_{g,P} \times \mathbb{R}_+ & \xrightarrow{\xi} & \overline{\mathcal{M}}_{g,P}^{\text{comb}}(\mathbb{R}_+) \\
\end{array}
$$

tell us how to use the combinatorial forgetful map. Namely, for every $\tilde{I} \in C_{P,q}^+$ we can associate to $[\overline{\omega}_q]^{r+1} \in H^{2r+2}(\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(\tilde{I}), D_q^{\text{comb}}(\tilde{I}))$ a homology class $[\overline{\omega}_q]^{r+1}$ in $H_{6g-6+2n-2r}(\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(\tilde{I}) \setminus D_q^{\text{comb}}(\tilde{I}))$, which is defined as the functional on $H_{6g-6+2n-2r}(\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(\tilde{I}) \setminus D_q^{\text{comb}}(\tilde{I}))$ given by

$$
\eta \mapsto \int_{\overline{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}}(\tilde{I})} \eta \wedge \omega_q^{r+1}.
$$

Thus, $\tilde{\xi}_*(\omega_q^{r+1}) = [\overline{\omega}_q]^{r+1}$ and $\pi_q^*(\omega_q^{r+1}) = \kappa_r^+$. Consequently, $\pi_q^{\text{comb}}([\overline{\omega}_q]^{r+1}) = \xi_* \kappa_r^+$. 

**COMBINATORIAL CLASSES ON $\overline{\mathcal{M}}_{g,n}$ ARE TAUTOGICAL**
Proposition 5.1. There is a deformation retraction

\[ \tilde{H}^q : \overline{M}_{g,p \cup \{q\}}(C_{P,q}) \times [0,1] \rightarrow \overline{M}_{g,p \cup \{q\}}(C_{P,q}) \]

such that \( \tilde{H}^0_q \) is the identity and \( \tilde{H}^1_q \) is the piecewise-linear retraction onto \( \overline{M}_{g,p \cup \{q\}}(\mathbb{R}_+^P \times \{0\}) \). Moreover, \( \tilde{H}^q_0(\overline{Y}_h) \subset \overline{Y}_h \) and \( \tilde{H}^q_1(D^\text{comb}_q) \subset D^\text{comb}_q \) for all \( t \in [0,1] \).

Proof. Consider a cell \( \tilde{\lambda}^{-1}(C_{P,q}) \cap (|\alpha| \times \mathbb{R}_+) \) inside \( \overline{M}_{g,p \cup \{q\}}(C_{P,q}) \). Denote by \( e_1, \ldots, e_h \) the coordinates of \( |\alpha| \times \mathbb{R}_+ \) corresponding to the unoriented edges of \( G_\alpha \) that border the hole \( q \) and by \( f_1, \ldots, f_k \) the remaining ones. Then it is sufficient to define \( \tilde{H}^q_t \) as the map that sends \( e_i \mapsto t \cdot e_i \) and \( f_j \mapsto f_j \) and to observe that all these deformation retractions glue to give a global \( H^q \). By definition, it is immediate that \( \tilde{H}^q_1(\overline{Y}_h) \subset \overline{Y}_h \) and one can also easily check that the locus \( D^\text{comb}_q \) is preserved. \( \square \)

![Figure 9. The deformation retraction \( \tilde{H}^q \) ](image)

Definition 5.2. The map \( H^q_0 : \overline{M}_{g,p \cup \{q\}}(C_{P,q}) \rightarrow \overline{M}_{g,p \cup \{q\}}(\mathbb{R}_+^P \times \{0\}) \) obtained from \( \tilde{H}^q_0 \) by restriction of the codomain is called shrinking of the \( q \)-th hole.

A consequence of the previous proposition is that we can compare \( [\mathbb{R}_+^{P+1}]^* \) with the combinatorial classes that live in \( \overline{M}_{g,p \cup \{q\}}(\mathbb{R}_+^P \times \{0\}) \) using the
following diagram.

\[
\begin{array}{ccc}
\mathcal{M}_{g,P\cup\{q\}}^\text{comb}(\mathbb{R}_+^* \times \{0\}) & \xrightarrow{\sim} & \mathcal{M}_{g,P\cup\{q\}}^\text{comb}(C_{P,q}) \\
\uparrow \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \uparrow \downarrow \\
\mathcal{M}_{g,P\cup\{q\}}^\text{comb}(C^+_{P,q}) & \xrightarrow{\mathcal{H}_q^g} & \mathcal{M}_{g,P\cup\{q\}}^\text{comb}(\mathbb{R}_+^* \times \{0\}) \\
\end{array}
\]

In particular, we can consider the functional \(\omega_q^{r+1}\) of \(\tilde{\omega}_q^r\) associated to the restriction of \(\omega_q^{r+1}\) to \(\mathcal{M}_{g,P\cup\{q\}}^\text{comb}(\tilde{t})\) with \(\tilde{t} \in C^+_{P,q}\) as a homology class in \(H_*^{g,P\cup\{q\}}(\tilde{t} \setminus D_q^{\text{comb}})\) and then we can look at its image in \(H_*^{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}})\) through \((\mathcal{H}_q^g)_*\).

Henceforth, with the aid of this last diagram

\[
\begin{array}{ccc}
H_*^{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}} & \xrightarrow{\xi_t} & H_*^{g,P\cup\{q\}}(C_{P,q}) \setminus D_q^{\text{comb}}) \\
\uparrow \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \uparrow \downarrow \\
H_*^{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}}, \Sigma_{g,P\cup\{q\}}^{\text{comb}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}}) & \cong & (\mathcal{H}_q^g)_* \mathcal{M}_{g,P\cup\{q\}}^\text{comb}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}})
\end{array}
\]

we obtain that, if we prove that \((\mathcal{H}_q^g)_*(\omega_q^{r+1}) = X\) in \(H_*^{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}}, \Sigma_{g,P\cup\{q\}}^{\text{comb}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}})\) with \(X\) a combinatorial cycle, then we have that \((\psi_q^r)^* = X\) in \(H_*^{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \setminus D_q^{\text{comb}}\).

6. CLASSES WITH ONE NONTRIVALENT VERTEX

Let \(P = \{p_1, \ldots, p_n\}\) be a nonempty set of markings and \(g \geq 0\) an integer such that \(2g - 2 + n > 0\). For every integer \(r \geq -1\) denote by \(\mathcal{W}_r\) the generalized combinatorial class on \(\mathcal{M}_{g,P\cup\{q\}}^\text{comb}\) corresponding to ribbon graphs whose vertices are all trivalent except one which has valency \(2r + 3\) and is marked by \(q\). Analogously, for every \(r \geq 0\) call \(\mathcal{W}_r\) the combinatorial class on \(\mathcal{M}_{g,P}^\text{comb}\) correspondent to ribbon graphs whose vertices are all trivalent except one which has valency \(2r + 3\) (in the case \(r = 0\) all the vertices are trivalent). In what follows, when there is no risk of ambiguity, we will use the same symbols \(\mathcal{W}_r\) and \(\mathcal{W}_r\) for the combinatorial classes and for the subcomplexes of the combinatorial moduli spaces the classes are supported on.

Before stating the first result, we need to introduce some auxiliary combinatorial classes. Call \(\mathcal{N}_{v_1,v_2}^q\) the subcomplex of \(\mathcal{M}_{g,P\cup\{q\}}^\text{comb}\) \(\{l_q = 0\}\) that parametrizes surfaces with a nonpositive component \(S_0\) of genus \(0\), such
that: $S_0$ is $g$-marked, it has two singular points and the two nodes identify
points of $S_0$ to vertices of valencies $v_1$ and $v_2$. Call $\mathcal{N}_{v_1,v_2}$ the subcomplex
of $\mathcal{M}^\text{comb}_{g,P}$ which parametrizes surfaces with a node that identifies a vertex
of valency $v_1$ and a vertex of valency $v_2$.

It is not difficult to check that, for odd $v_1$ and $v_2$, these subcomplexes
define cycles, which in fact could also be obtained as images of combinatorial
classes of the type $\mathcal{W}$ through “combinatorial boundary maps”.

\textbf{Theorem A.} For any $g$ and $n \geq 1$, the equality

$$\mathcal{W}^g_{2r+3} + \sum_{i,j \geq 0} (2i+1)(2j+1)\mathcal{N}^g_{2i+1,2j+1} = \frac{(2r+2)!}{(r+1)!} (\psi^{r+1}_q)^*$$

holds in $H_{2s}(\mathcal{M}^\text{comb}_{g,P\cup\{q\}}, \Sigma^q_{g,P})$ for every $r \geq -1$, where $s = 3g - 3 + n - r$.
As a consequence, for $r \geq 1$ the equality

$$\mathcal{W}^g_{2r+3} + \sum_{i,j \geq 0} (2i+1)(2j+1)\mathcal{N}^g_{2i+1,2j+1} = 2^{r+1}(2r+1)!! \kappa^*_r$$

holds in $H_{2s}(\mathcal{M}^\text{comb}_{g,P}, \pi_q(\Sigma^q_{g,P}))$.

\textbf{Strategy.} First, notice that for $r \geq 0$ and $\vec{l} = (l,0) \in \mathbb{R}^P_+ \times \{0\}$ the cycles
$\mathcal{W}^g_{2r+3}(\vec{l})$ and $\mathcal{N}^g_{2i+1,2j+1}(\vec{l})$ live also in $H_{2s}(\mathcal{M}^\text{comb}_{g,P\cup\{q\}}(\vec{l}) \setminus D^\text{comb}_q(\vec{l}))$, because
$\mathcal{W}^g_{2r+3}(\vec{l}) \cap D^\text{comb}_q(\vec{l}) = \emptyset$ and $\mathcal{N}^g_{2i+1,2j+1}(\vec{l}) \cap D^\text{comb}_q(\vec{l}) = \emptyset$.

Then, considerations developed in Section 5 show that it is sufficient to compare

$$\frac{(2r+2)!}{(r+1)!} (\psi^{r+1}_q)^*$$

and

$$\mathcal{W}^g_{2r+3} + \sum_{i,j \geq 0} (2i+1)(2j+1)\mathcal{N}^g_{2i+1,2j+1}$$

as elements of $H_{2s}(\mathcal{M}^\text{comb}_{g,P\cup\{q\}}(\mathbb{R}^P_+ \times \{0\}) \setminus D^\text{comb}_q, \Sigma^\text{comb}_{g,P\cup\{q\}}(\mathbb{R}^P_+ \times \{0\}) \setminus D^\text{comb}_q)$;
so we couple them with classes

$$[\eta] \in H^2(\mathcal{M}^\text{comb}_{g,P\cup\{q\}}(\mathbb{R}^P_+ \times \{0\}) \setminus D^\text{comb}_q, \Sigma^\text{comb}_{g,P\cup\{q\}}(\mathbb{R}^P_+ \times \{0\}) \setminus D^\text{comb}_q)$$

and a simple computation proves the first relation.

For the second claim, it is sufficient to recall that we can push the first relation forward, using the following diagram

$$\begin{array}{ccc}
H_{2s}(\mathcal{M}_{g,P\cup\{q\}} \setminus D_q, \Sigma^q_{g,P} \setminus D_q) & \xrightarrow{\pi_q,*} & H_{2s}(\mathcal{M}^\text{comb}_{g,P\cup\{q\}}(\vec{l}) \setminus D^\text{comb}_q, \Sigma^\text{comb}_{g,P\cup\{q\}}(\vec{l}) \setminus D^\text{comb}_q) \\
\mathcal{W}^g_{2r+3} & \xrightarrow{\mathcal{W}^g_{2r+3}} & \mathcal{W}^g_{2r+3} \\
H_{2s}(\mathcal{M}^\text{comb}_{g,P}, \pi_q(\Sigma^q_{g,P})) & \xrightarrow{\pi_q,*} & H_{2s}(\mathcal{M}^\text{comb}_{g,P}(\vec{l}), \pi_q^\text{comb}(\Sigma^\text{comb}_{g,P})(\vec{l}))
\end{array}$$
in order to obtain the second relation
\[ \pi_{q,*}^{\text{comb}} \left( W_{2r+3}^q + \sum_{i,j \geq 0, i+j=r-1} (2i+1)(2j+1) \mathcal{N}_{2i+1,2j+1}^q \right) = \frac{(2r+2)!}{(r+1)!} \pi_{q,*}(\psi_{r+1}^q)^* \]
thus concluding the argument.

**Proof of Theorem A.** Consider a closed PL differential form \( \eta \) of degree \( 2s \) on \( (\overline{\mathcal{M}}_{g,P \cup \{q\}}^\text{comb} \setminus D_q^\text{comb}) \) that vanishes on \( (\Sigma_{g,P \cup \{q\}}^\text{comb} \setminus D_q^\text{comb})(\mathbb{R}_P^+ \times \{0\}) \).

The form \( (\mathcal{H}_0^q)^* \eta \wedge \omega_r^{q+1} \) extends by zero to \( \overline{\mathcal{M}}_{g,P \cup \{q\}}^\text{comb} \), because \( (\mathcal{H}_0^q)^{-1}(D_q^\text{comb} \cap \overline{\mathcal{M}}_{g,P \cup \{q\}}^\text{comb})(C_{P,q}^+) \subset \overline{Y}_1(C_{P,q}^+) \) is an inclusion in a closed neighbourhood and \( \pi_{q,+}^q \) vanishes on \( \overline{Y}_1 \). Moreover, for simple reasons of degree, the restriction of \( (\mathcal{H}_0^q)^* \eta \wedge \omega_r^{q+1} \) to \( \overline{\mathcal{M}}_{g,P \cup \{q\}}^\text{comb} \) has support contained inside \( \overline{Y}_{2r+3}(\tilde{l}) \) for every \( \tilde{l} \in C_{P,q}^+ \). In fact, the restriction of \( \pi_{q,+}^q \) has support inside \( \overline{Y}_{\geq 2r+3}(\tilde{l}) \), while the restriction of \( (\mathcal{H}_0^q)^* \eta \) has support inside \( \overline{Y}_{\leq 2r+3}(\tilde{l}) \). Now decompose \( \overline{Y}_{2r+3}(C_{P,q}^+) \) into three families of subsets:

1. the closure \( \overline{Y}_{2r+3}^\text{disk}(C_{P,q}^+) \) of the locus of graphs where the surface \( \bar{T}_q \) is a disk (see Subsection 2.1); in this case \( \mathcal{H}_0^q(\overline{Y}_{2r+3}^\text{disk}(C_{P,q}^+)) \) is exactly \( \overline{W}_{2r+3}^q(\mathbb{R}_P^+ \times \{0\}) \)

\[ \overline{Y}_{2r+3}^\text{disk} \]
\[ \overline{Y}_{2r+3}^\text{surf} \]

\[ \overline{Y}_{1,3} \]

**Figure 10.** Three examples of loci \( \overline{Y} \)
Since the volume of the difference \( \int_0 = \lim \) of the closure \( H^0_\nu \) is exactly \( \mathcal{N}^0_{v_1,v_2}(\mathbb{R}_+^* \times \{0\}) \).

Remark that \( L \), hence \( \lambda \) the closure \( \mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\}) \) of graphs with one nonpositive component of genus \( h \) which has the \( q \)-marking and \( \nu \) nodes corresponding to vertices of valencies \( v_1,\ldots,v_\nu \).

Notice that all the subcomplexes \( \mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\}) \) are contained inside \( \Sigma_{g,P\cup\{q\}}(\mathbb{R}_+^* \times \{0\}) \), hence \( \langle H^0_\nu \rangle^* \eta \) vanishes on \( \mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\}) \).

Choose \( 0 < \epsilon < L'' \ll L' \) and notice that \( \langle H^0_\nu(\mathcal{Y}_{2\nu+3}([L'',L']^n \times \{\epsilon\})) \rangle \) contains

\[
(\bigcup_{h,v_1,...,v_\nu} \mathcal{Z}_{h,v_1,...,v_\nu} \cup W_{2\nu+3} \cup_{v_1,v_2} \mathcal{N}_{v_1,v_2})([L'',L' - \epsilon^n] \times \{0\})
\]

and is contained inside

\[
(\bigcup_{h,v_1,...,v_\nu} \mathcal{Z}_{h,v_1,...,v_\nu} \cup W_{2\nu+3} \cup_{v_1,v_2} \mathcal{N}_{v_1,v_2})([L'' - \epsilon^n,L']^n \times \{0\})
\]

Since the volume of the difference \([L'' - \epsilon,L']^n \setminus [L'',L' - \epsilon^n]^n \) goes to zero as \( \epsilon \) decreases, we have

\[
\int_{[L'',L']^n} d\tilde{p}_1 \land \cdots \land d\tilde{p}_n \int_{\mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\})} \psi_q^{n+1} \circ \bar{\xi}^*(\langle H^0_\nu \rangle^* \eta) = 0
\]

\[
= \lim_{\epsilon \to 0} \int_{Y_{2\nu+3}([L'',L']^n \times \{\epsilon\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \bar{\omega}_q^{n+1} \land \langle H^0_\nu \rangle^* \eta
\]

\[
= \lim_{\epsilon \to 0} \left( \int_{W_{2\nu+3}([L'',L']^n \times \{\epsilon\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \bar{\omega}_q^{n+1} \land \langle H^0_\nu \rangle^* \eta
\]

\[
+ \sum_{v_1+v_2=2r} \int_{\mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \bar{\omega}_q^{n+1} \land \langle H^0_\nu \rangle^* \eta
\]

\[
+ \sum_{h,v_1,...,v_\nu} \int_{\mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \bar{\omega}_q^{n+1} \land \langle H^0_\nu \rangle^* \eta
\]

\[
= \lim_{\epsilon \to 0} \left( \int_{W_{2\nu+3}([L'',L' - \epsilon^n] \times \{0\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \eta \int_{E_{2\nu+3}(\epsilon)} \bar{\omega}_q^{n+1} +
\]

\[
+ \sum_{v_1+v_2=2r} \int_{\mathcal{Z}_{h,v_1,...,v_\nu}(\mathbb{R}_+^* \times \{0\})} \lambda^*(d\tilde{p}_1 \land \cdots \land d\tilde{p}_n) \land \eta \int_{E_{2\nu+3}(\epsilon)} \bar{\omega}_q^{n+1}
\]

\[
= \int_{[L'',L']^n} d\tilde{p}_1 \land \cdots \land d\tilde{p}_n \left( \int_{W_{2\nu+3}(\epsilon)} \eta \int_{E_{2\nu+3}(\epsilon)} \bar{\omega}_q^{n+1} +
\right)
\]
that volumes of the differences ε are the (unoriented) edges of the q.

Remark. In the first equality, we used the push-forward through the map

\[ \tilde{\xi}_\varepsilon : \mathcal{M}_{g,PU(q)}^\text{com} \times \mathbb{R}_+^P \times \{\varepsilon\} \to \mathcal{M}_{g,PU(q)}^\text{com}(\mathbb{R}_+ \times \{\varepsilon\}). \]

In the third equality, we used that \( H^q_0 \) restricts to

\[ \mathcal{V}^\text{disk}_{2r+3}([L'', L']^n \times \{\varepsilon\}) \leftarrow \mathcal{V}^\text{disk}_{2r+3}([L'' - \varepsilon, L']^n \times \{0\}) \]

where the lower map is a fibration with fiber \( F^\text{disk}_{2r+3}(\varepsilon) \), and the fact that the volumes of the differences \( \mathcal{V}^\text{disk}_{2r+3}([L'', L']^n \times \{\varepsilon\}) \backslash (H^q_0)^{-1}(\mathcal{V}^\text{disk}_{2r+3}([L'', L' - \varepsilon]^n \times \{0\})) \) and \( \mathcal{V}^\text{disk}_{2r+3}([L'' - \varepsilon, L']^n \times \{0\}) \backslash \mathcal{V}^\text{disk}_{2r+3}([L'', L' - \varepsilon]^n \times \{0\}) \) tend to zero with \( \varepsilon \). Analogous considerations hold for \( F^\text{cyl}_{v_1, v_2} \) and \( \mathcal{V}^\text{cyl}_{v_1, v_2} \).

It is easy to see that \( F^\text{disk}_{2r+3}(\varepsilon) \) is a simplex of dimension \( 2r + 2 \) with affine coordinates \( e_0, \ldots, e_{2r+2} \) subject to the constraint \( \sum_{j=0}^{2r+2} e_j = 2\varepsilon \), where \( e_j \) are the (unoriented) edges of the \( q \)-marked hole. It is also immediate to see that \( \mathcal{V}^\text{cyl}_{v_1, v_2} \) is equal to \( (r + 1)!d(e_0^2) \cdots d(e_{2r+2}^2) \) on \( F^\text{disk}_{2r+3}(\varepsilon) \), so that

\[ \int_{F^\text{cyl}_{v_1, v_2}(\varepsilon)} \mathcal{V}^\text{cyl}_{v_1, v_2} = (r + 1)! \text{vol}(\Delta_{2r+2}) = \frac{(r + 1)!}{(2r + 2)!}. \]

A simple computation shows that \( \mathcal{V}^\text{cyl}_{v_1, v_2} \) vanishes on \( F^\text{cyl}_{v_1, v_2} \) if \( v_1 \) and \( v_2 \) are even; while \( \mathcal{V}^\text{cyl}_{v_1, v_2} = (r + 1)!d(e_0^2) \cdots d(e_{2r+2}^2) \) if \( v_1 \) and \( v_2 \) are odd, where \( 2e_0 + \sum_{j=1}^{2r+2} e_j = 2\varepsilon \) and \( e_0 \) is the “separating” edge of the cylinder. We deduce that, for \( v_1 \) and \( v_2 \) odd,

\[ \int_{F^\text{cyl}_{v_1, v_2}(\varepsilon)} \mathcal{V}^\text{cyl}_{v_1, v_2} = v_1 v_2 \frac{(r + 1)!}{(2r + 2)!} \]

because \( F^\text{cyl}_{v_1, v_2} \) contains \( v_1 v_2 \) top-dimensional simplices.

Hence, we conclude that

\[ \frac{(2r + 2)!}{(r + 1)!} \int_{\mathcal{M}_{g,PU(q)}} \psi^{v_1, v_2} \sim \tilde{\xi}_{\varepsilon}^*(H^q_0)^{\ast}[\eta] = \int_{\mathcal{V}^\text{disk}_{2r+3}(\tilde{\eta})} \eta^{v_1, v_2} + \sum_{i,j \geq 0, i+j=r-1} (2i+1)(2j+1) \int_{\mathcal{V}^\text{cyl}_{2i+1,2j+1}(\tilde{\eta})} \eta^{v_1, v_2}. \]
and the proof is complete. \hfill \square

**Corollary A.1.** For every \( g \) and \( |P| = n \geq 1 \) such that \( 2g - 2 + n > 0 \) the following equalities hold
\[
\bar{W}_5 + \delta_{irr}^g + \sum_{g',I \neq \emptyset,P} \delta_{g',I}^g = 12(\psi_q^2)^n \quad \text{in } H_{6g-8+2n}(\overline{\mathcal{M}}_{g,P\cup\{q\}},\Sigma_g^q)
\]
\[
\bar{W}_5 + \delta_{irr}^g + \sum_{g',I \neq \emptyset,P} \delta_{g',I}^g = 12\kappa_1^g \quad \text{in } H_{6g-8+2n}(\overline{\mathcal{M}}_{g,P},\Sigma_g^p)
\]
where \( \delta_{g',I}^g \) is the image of the morphism
\[
\overline{\mathcal{M}}_{g',I\cup\{p'\}} \times \overline{\mathcal{M}}_{0,\{q,q',q''\}} \times \overline{\mathcal{M}}_{g-g',I\cup\{p''\}} \to \overline{\mathcal{M}}_{g,P\cup\{q\}}
\]
that glues \( p' \) with \( q' \) and \( p'' \) with \( q'' \) (analogously for \( \delta_{irr}^g \)).

The second equality of the previous corollary has been proven first by Arbarello and Cornalba \[AC96\] in a very different manner. Here it is a consequence of the proof of Theorem A and of the remark at the end of Section 4. In fact, the difference between \( \pi_q(\Sigma_g^q) \) and \( \Sigma_g^p \) has complex codimension three. Moreover, for \( r = 1 \) all simplices of top dimension in \( \mathcal{T}^m \) have \( v_1 = v_2 = 1 \).

### 7. More on the Shrinking Map and the Forgetful Map

We now want to examine the case of an arbitrary class \( \overline{W}_{m_*,\rho,P} \) on \( \overline{\mathcal{M}}_{g,P\cup\{Q\}}^{\text{comb}} \) for some \( \rho : Q \to \mathbb{N} \).

The ideas involved in the proof are the same as before, but more care is needed. The main difference is that \( \pi_Q(\Sigma_g^Q) \) is not contained in \( \partial\overline{\mathcal{M}}_{g,P} \), as in the case \( Q = \{ q \} \).

However, we do not need to consider homology classes relative to \( \Sigma_g^Q \). In fact, the singular locus of \( \overline{\mathcal{M}}_{g,P\cup\{Q\}}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \) is smaller than \( \Sigma_g^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \). In this way, we can adapt the combinatorial forgetful map and the shrinking map to the case \( |Q| > 1 \).

Fix \( P = \{ p_1, \ldots, p_n \}, \ Q' = \{ q_1, \ldots, q_s \} \) and \( Q'' = \{ q_{s+1}, \ldots, q_{s+u} \} \), and let \( Q = Q' \cup Q'' \). Consider the forgetful map \( \pi_{Q''} : \overline{\mathcal{M}}_{g,P\cup\{Q''\}} \to \overline{\mathcal{M}}_{g,P\cup\{Q''\}} \) and call \( \overline{C}_{g,P\cup\{Q''\}} \) the inverse image \( \pi_{Q''}^{-1}(\overline{\mathcal{M}}_{g,P\cup\{Q''\}}) \), which is the locus of curves with one component of geometric genus \( g \) plus some rational tails, each one containing at most one point of \( P \cup Q' \); moreover, call \( \partial\overline{C}_{g,P\cup\{Q''\}} \) its boundary
\[
\overline{\mathcal{M}}_{g,P\cup\{Q''\}} \setminus \overline{C}_{g,P\cup\{Q''\}}.
\]

On the combinatorial side, consider the map
\[
\xi : \overline{\mathcal{M}}_{g,P\cup\{Q''\}} \times \mathbb{R}_+^P \times \{0\}^Q \to \overline{\mathcal{M}}_{g,P\cup\{Q''\}}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q)
\]
and call \( \overline{C}_{g,P\cup\{Q''\}}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \) the image of \( \overline{C}_{g,P\cup\{Q''\}}^{\text{comb}} \times \mathbb{R}_+^P \times \{0\}^Q \), and analogously \( \partial\overline{C}_{g,P\cup\{Q''\}}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \) its boundary \( \overline{\mathcal{M}}_{g,P\cup\{Q''\}} \setminus \overline{C}_{g,P\cup\{Q''\}}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \).
Remember that $D_{Q',P} \subset \overline{\mathcal{M}}_{g,p\cup q}$ is the union of all divisors of the type $\delta_{0,q_1,...,q_j,\{p_i\}}$ for $p_i \in P$ and $\{q_j,\ldots, q_{j+1}\} \subset Q'$. Call $D_{Q',P}^{\text{comb}}$ its image through $\xi$ and define $\pi_{Q'}^{\text{comb}}$ as the composition $\pi_{q_{j+1}} \cdots \pi_{q_{j+u}}$, so that the following diagram

\[
\begin{array}{c}
\overline{\mathcal{M}}_{g,p\cup q} \times \mathbb{R}_+^P \times \{0\}^Q \\
\downarrow \pi_{Q'}^{\text{comb}} \\
\overline{\mathcal{M}}_{g,p\cup q'}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \end{array} \quad \begin{array}{c}
\overline{\mathcal{M}}_{g,p\cup q} \setminus D_{Q',P} \times \mathbb{R}_+^P \times \{0\}^Q \\
\downarrow \pi_{Q'}^{\text{comb}} \\
\overline{\mathcal{M}}_{g,p\cup q'}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q) \\
\end{array}
\]

is commutative.

**Lemma 7.1.** The locus $(C_{Q',P}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\mathbb{R}_+^P \times \{0\})$ is smooth.

**Proof.** Notice that the restriction of $\xi$ factorizes as follows

\[
\begin{array}{c}
(C_{Q',P}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\mathbb{R}_+^P \times \{0\}) \\
\downarrow \xi \\
(C_{Q',P}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\mathbb{R}_+^P \times \{0\}) \\
\end{array} \quad \begin{array}{c}
(C_{Q',P}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\mathbb{R}_+^P \times \{0\}) \\
\end{array}
\]

and that the locus we are interested in is homeomorphic to a fiber product of $u$ copies of $C_{Q',P}^{\text{comb}} \setminus D_{Q',P}$ over $\mathcal{M}_{g,p\cup q}$, which is smooth. \qed

We now want to show that for every $\tilde{I} \in \mathbb{R}_+^P \times \{0\}$ we can lift homology classes via $\xi$ from

\[
H_*(\overline{\mathcal{M}}_{g,p\cup q}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\tilde{I}), (\partial C_{Q',P}^{\text{comb}} \setminus D_{Q',P}^{\text{comb}})(\tilde{I})
\]

to

\[
H_*(\overline{\mathcal{M}}_{g,p\cup q} \setminus D_{Q',P})(\tilde{I}), (\partial C_{Q',P} \setminus D_{Q',P})(\tilde{I})
\]

using a sort of Lefschetz duality.

**Remark.** Let be given a compact connected triangulated space $K$ and two nonempty proper subcomplexes $F$ and $G$, such that $K \setminus (F \cup G)$ is a connected oriented topological manifold of dimension $d$. Suppose that $F$ (resp. $G$) has a closed neighbourhood $N_F$ (resp. $N_G$) that retracts on $F$ (resp. on $G$) by deformation. Moreover, suppose that $\partial N_F \setminus N_G$ is a topological manifold of dimension $d - 1$. Then we can define a duality homomorphism

\[
H_k(K \setminus N_F, N_G \setminus N_F) \rightarrow H_ {d-k}(K \setminus (N_F \cup N_G), \partial N_F \setminus N_G)
\]
noticing that every dual cocycle vanishes on $\partial N_F \setminus N_G$. Moreover, this map fits in the following diagram

$$
\begin{array}{c}
\begin{array}{c}
H^{d-k-1}(\partial N_F \setminus N_G) \\ \cong \\
H_k(\partial N_F \cap N_G)
\end{array}
\xrightarrow{\cong}
\begin{array}{c}
H^{d-k}(K \setminus (N_F^0 \cup N_G), \partial N_F \setminus N_G) \\
\cong
\end{array}
\xrightarrow{\cong}
\begin{array}{c}
H^{d-k}(K \setminus (N_F \cup N_G))
\end{array}
\end{array}
$$

where the first row is the exact sequence of the couple

$$(K \setminus (N_F^0 \cup N_G), \partial N_F \setminus N_G)$$

and the second row is the exact sequence of the triple

$$(K \setminus N_F^0, \partial N_F \cup (N_G \setminus N_F^0), N_G \setminus N_F^0),$$

and we are using the homotopy equivalences

$$K \setminus (N_F^0 \cup N_G) \simeq K \setminus (N_F \cup N_G)$$

$$(K \setminus N_F, N_G \setminus N_F) \simeq (K \setminus N_F^0, N_G \setminus N_F^0).$$

Notice that we are identifying

$$H_k(\partial N_F, \partial N_F \cap N_G) \quad \text{and} \quad H_k(\partial N_F \cup (N_G \setminus N_F^0), N_G \setminus N_F^0)$$

in the following way. First we have that

$$H_k(\partial N_F, \partial N_F \cap N_G) \cong H_k(\partial N_F \setminus G, \partial N_F \cap (N_G \setminus G))$$

by excision of $\partial N_F \cap G$. Then we use that $\partial N_F \cap (N_G \setminus G)$ has a tubular neighbourhood inside $N_G \setminus G$ and we get

$$H_k(\partial N_F \setminus G, \partial N_F \cap (N_G \setminus G)) \cong H_k(\partial N_F \cup (N_G \setminus N_F^0) \setminus G, N_G \setminus (N_F^0 \cup G)).$$

Finally, the excision of $G \setminus N_F^0$ gives

$$H_k(\partial N_F \cup (N_G \setminus N_F^0) \setminus G, N_G \setminus (N_F^0 \cup G)) \cong H_k(\partial N_F \cup (N_G \setminus N_F^0), N_G \setminus N_F^0)$$

which establishes the desired identification. Hence, we can conclude that the vertical arrow in the middle is an isomorphism by the Five Lemma.

Now we want to show that the hypotheses of the previous remark are satisfied in two particular situations. In the first case, $F = D_{Q''} \setminus P$, $G = \partial C_{g,P \cup Q}$, and $K = \overline{M}_{g,P \cup Q}$, so we can immediately conclude because $K$ is smooth and $F$ is a divisor with normal crossings (as $Q$-varieties). In the second case, $F = D_{Q''}^{comb} \setminus (\tilde{l})$, $G = \partial C_{g,P \cup Q}^{comb}(\tilde{l})$ and $K = \overline{M}_{g,P \cup Q}^{comb}(\tilde{l})$, and we need to prove that there exist “good” neighbourhoods $N_F$ and $N_G$. Call $\overline{C}_{g,P \cup Q}$ the fiber product of all $\overline{M}_{g,P \cup Q} \cup (\{q_{i+1}\} \setminus \{q_{i+1}\})$ for $i = 1, \ldots, u$ over $\overline{M}_{g,P \cup Q}$. The continuous map

$$\prod_{i=1, \ldots, u} C_{g,P \cup Q}^{q_{i+1}} \setminus D_{(q_{i+1})} \setminus P \rightarrow \overline{M}_{g,P \cup Q}^{comb}(\tilde{l})$$
does not extend to $\tilde{C}_{g,\cup Q'}$. However, there is a well-defined map $\M_{g,\cup Q}^\text{comb} \to \M_{g,\cup Q}(\bar{1})$ and an algebraic morphism $\M_{g,\cup Q} \to \tilde{C}_{g,\cup Q'}$. As a consequence, even though $\M_{g,\cup Q}(\bar{1})$ may not be an algebraic space, there is a resolution $\tilde{C}_{g,\cup Q'}$, obtained from $\tilde{C}_{g,\cup Q'}$ by performing iterated blow-ups with centers outside

\[ \prod_{i=1,\ldots,u} C_{g,\cup Q'}^q \setminus D_{\{q_{i+1}\},P}, \]

such that the following diagram commutes

\[ \begin{array}{ccc}
\M_{g,\cup Q}^\text{comb} & \rightarrow & \M_{g,\cup Q}(\bar{1}) \\
\downarrow & & \downarrow \\
\tilde{C}_{g,\cup Q'} & \rightarrow & \tilde{C}_{g,\cup Q'} \\
\end{array} \]

and the inverse image $\tilde{D}_{Q''P} \subset \tilde{C}_{g,\cup Q'}$ of $D_{Q''P}^\text{comb}$ is a divisor with normal crossings inside a smooth variety. Hence, $\tilde{D}_{Q''P}$ has a closed neighbourhood whose boundary is a closed manifold of real codimension 1 and we can define $N_F$ to be its image in $\M_{g,\cup Q}(\bar{1})$. Also the inverse image of $\partial C_{g,\cup Q'}^q \setminus D_{\{q_{i+1}\},P}$ through last map is a divisor with normal crossings, so we can choose the image of an adequate neighbourhood of this divisor as $N_G$.

Thus, we can consider a cycle on $(\M_{g,\cup Q}^\text{comb} \setminus D_{Q''P}^\text{comb})(\bar{1})$ with boundary contained in $(\partial C_{g,\cup Q'}^q \setminus D_{Q''P}^\text{comb})(\bar{1})$, dualize it, pull it back and dualize it again, in order to get a cycle on $(\M_{g,\cup Q} \setminus D_{Q''P}) \times \{\bar{1}\}$ relative to $(\partial C_{g,\cup Q'} \setminus D_{Q''P}) \times \{\bar{1}\}$. This defines the desired pull-back map in homology. In what follows we will denote by the same symbols combinatorial classes and their lifts.

Remember that, for every $a_1, \ldots, a_s, b_1, \ldots, b_u \geq 1$, the class

\[ \psi^{a_1}_{q_1} \cdots \psi^{a_s}_{q_s} \psi^{b_1}_{q_{s+1}} \cdots \psi^{b_u}_{q_{s+u}} \]

which is equal to

\[ \pi^{a_1}_{q_1, \ldots, q_2}, \pi^{a_2}_{q_{s+u}, \ldots, q_3}, \ldots, \pi^{b_u}_{q_{s+u-1}, q_{s+u}} \]

in $H^*(\M_{g,\cup Q})$, admits a natural lift to $H^*(\M_{g,\cup Q}, D_{Q''P})$ (see Section 3). Thus, we can lift the Poincaré dual of this class from $H_*(\M_{g,\cup Q})$ to $H_*(\M_{g,\cup Q} \setminus D_{Q''P})$, and so it makes sense to compare in $H_*(\M_{g,\cup Q} \setminus D_{Q''P})$.
We compute the Euler characteristic, we immediately see that a combinatorial class. We obtain the required representative for a tautological class to compare with closure of the locus of graphs where all the retractions.

For every $k = 1, \ldots, s + u$, call $Q_k := \{q_1, \ldots, q_k\}$ and, analogously to Section 5, call $C_{P,k}$ the subset of $\tilde{l} \in \mathbb{R}_+^P \times \{0\}^Q$ defined by

$$\begin{cases}
l_{q_j} = 0 & \text{for all } j = k + 1, \ldots, s + u \\
\sum_{i=j+1}^{k} l_{q_i} < l_{q_j} & \text{for all } j = 1, \ldots, k - 1 \\
\sum_{i=1}^{k} l_{q_i} < l_{p_j} & \text{for all } j = 1, \ldots, n
\end{cases}$$

and set $C_{P,k}^+ := C_{P,k} \cap \{l_{q_k} > 0\}$. Define coherently $C_{P,0} := \mathbb{R}_+^P \times \{0\}^Q$.

Call $\mathcal{H}_{0}^{q_i} : \overline{\mathcal{M}}_{g,P \cup Q}(C_{P,s+u}) \to \overline{\mathcal{M}}_{g,P \cup Q}(C_{P,0})$ the composition $\mathcal{H}_{0}^{q_1} \mathcal{H}_{0}^{q_2} \cdots \mathcal{H}_{0}^{q_{s+u}}$ of all the retractions

$$\mathcal{H}_{0}^{q_i} : \overline{\mathcal{M}}_{g,P \cup Q}(C_{P,i}) \to \overline{\mathcal{M}}_{g,P \cup Q}(C_{P,i-1})$$

and remark that $\overline{\mathcal{M}}_{g,P \cup Q}(C_{P,s+u})$. As a consequence, if we call $\Upsilon_{t_1, \ldots, t_{s+u}} \subset \overline{\mathcal{M}}_{g,P \cup Q}$ the closure of the locus of graphs where

- the $Q$-marked holes have positive perimeters
- the hole marked by $q_{s+u}$ consists of $t_{s+u}$ distinct edges
- for every $i = 1, \ldots, s + u - 1$ the hole marked by $q_i$ consists of $t_i$ distinct edges beside those which border the holes marked by $q_{i+1}, \ldots, q_{s+u}$,

then we notice that the restriction of this last PL differential form to $\overline{\mathcal{M}}_{g,P \cup Q}(\tilde{l})$ with $\tilde{l} \in C_{P,s+u}^+$ has support contained in $\Upsilon_{\geq 2, \ldots, \geq 2}(C_{P,s+u}^+)$. By a simple computation of Euler characteristic, we immediately see that $D_{Q''_s,P}^{\text{comb}}(\tilde{l}) \cap \Upsilon_{\geq 2, \ldots, \geq 2}(\tilde{l}) = \emptyset$ and so the previous PL differential form vanishes on $D_{Q''_s,P}^{\text{comb}}(\tilde{l})$. Thus, it produces a class in $H_*(\overline{\mathcal{M}}_{g,P \cup Q} \setminus D_{Q''_s,P}^{\text{comb}}(\tilde{l}))$, which we can push forward to $H_*(\overline{\mathcal{M}}_{g,P \cup Q} \setminus D_{Q''_s,P}^{\text{comb}}(\mathbb{R}_+^P \times \{0\}^Q))$ through $\mathcal{H}_{0}^{q_i}$. In this way, we obtain the required representative for a tautological class to compare with a combinatorial class.
M → g,P

we introduce the last type of combinatorial classes. Then this equality lifts to $\pi_{Q''}$

As in the previous section, fix $\pi = (g, P, Q, \partial M_{g, P, Q})$ and suppose we have already proven an equality of the type $\text{comb}_0(Q) \cup Q' \subseteq \partial M_{g, P, Q}$, where $Q$ is a combinatorial class. Then this equality lifts to

$X = (\pi_{Q''})^* (\psi_{q_1}^{\alpha_1} \cdots \psi_{q_{s+u}}^{\alpha_u})^*$

in $H_*(\text{comb}_{g, P, Q'}, \partial M_{g, P, Q'})$. Moreover, we can push it forward to get

$(\pi_{Q''})_*(X) = (\pi_{Q''})_*(\psi_{q_1}^{\alpha_1} \cdots \psi_{q_{s+u}}^{\alpha_u})^*$

in $H_*(\text{comb}_{g, P, Q'}, \partial M_{g, P, Q'})$.

8. Classes with many nontrivalent vertices

As in the previous section, fix $P = \{p_1, \ldots, p_n\}$, $Q' = \{q_1, \ldots, q_s\}$ and $Q'' = \{q_{s+1}, \ldots, q_{s+u}\}$, and let $Q = Q' \cup Q''$. Moreover, let be given $m_* = (0, m_0, m_1, \ldots)$ and $\rho : Q \to \mathbb{N}$ in such a way that $m_i = m_i^\rho$ for every $i > 0$ and $m_0 \geq m_0^\rho$. Clearly, one must have $4g - 4 + 2|P| = \sum_{i \geq 0} (2i + 1)m_i$. In what follows we only consider combinatorial classes $\text{comb}_{M, \rho, P}$ with $\rho$ taking nonnegative values, because proofs and notations are simpler in this case.

As we are interested in cycles in (M\text{comb}_{g, P, Q} \setminus D\text{comb}_{g, P, Q'}) that are sent through $\pi_{Q''}$ to combinatorial cycles in (M\text{comb}_{g, P, Q', Q''} \setminus D\text{comb}_{g, P, Q''}'), now we introduce the last type of combinatorial classes $\text{comb}_{M, \rho, P}$ we will have to deal with.
Notation. We denote by \( \mathcal{P}_Q \) the set of partitions of \( Q \). We denote by \( \mathcal{P}_{Q,Q'} \) the subset of \( \mathcal{P}_Q \) consisting of all \( M = \{\mu_1, \ldots, \mu_k\} \) such that the restriction \( M \cap Q' := \{\mu_1 \cap Q', \ldots, \mu_k \cap Q'\} \) is the discrete partition of \( Q' \). For every \( q \in Q' \) we will denote by \( \mu_q \) the element of \( M \) that contains \( q \).

Let \( M = \{\mu_1, \ldots, \mu_k\} \in \mathcal{P}_Q \) be a partition of \( Q \), and set \( I_M := \{\iota_{\mu_1}, \ldots, \iota_{\mu_k}\} \). For \( l \in \mathbb{R}^P_0 \setminus \{0\} \) and \( \tilde{l} = (l, 0) \in \mathbb{R}^P_{\geq 0} \times \{0\} \), consider the following commutative diagram

\[
\begin{array}{ccc}
\overline{\mathcal{M}}_{g,P \cup I_M} \times \prod_{\mu \in M} \overline{\mathcal{M}}_{0,\mu \cup \{\iota'_\mu\}} & \xrightarrow{\vartheta^r_{M,P}} & \overline{\mathcal{M}}_{g,P \cup Q} \\
\downarrow & & \downarrow \\
\overline{\mathcal{M}}_{g,P \cup I_M}(l, 0) & \xrightarrow{\vartheta^r,P_{\text{comb}}} & \overline{\mathcal{M}}_{g,P \cup Q}(\tilde{l})
\end{array}
\]

where the map \( \vartheta^r_{M,P} \) glues the points \( \iota_\mu \) with \( \iota'_\mu \) together for every \( \mu \in M \) and, if necessary, stabilizes the curve; while \( \vartheta^r_{M,P_{\text{comb}}} \) glues a nonpositive \( \mu \)-marked sphere on \( \iota_\mu \) and, if necessary, stabilizes the surface and reduces the resulting dual graph. Both the horizontal maps are closed immersions.

Remark that in the diagram we have considered \( \overline{\mathcal{M}}_{0,2} \) as a point.

Call \( \delta^r_{M,P} \) the image of \( \vartheta^r_{M,P} \) and \( \delta^r_{M,P_{\text{comb}}}(\tilde{l}) \) the image of \( \vartheta^r_{M,P_{\text{comb}}} \). Notice that, if \( M \) does not belong to \( \mathcal{P}_{Q,Q'} \), then \( \delta^r_{M,P} \) is contained inside \( \partial C_{g,P \cup Q} \) and \( \delta^r_{M,P_{\text{comb}}}(\tilde{l}) \) is contained inside \( \partial C_{g,P \cup Q'}(\tilde{l}) \).

For every partition \( M \), define the function \( \rho^r_M \) as

\[
\rho^r_M : I_M \to \mathbb{N} \\
\iota_\mu \to \rho_\mu := \sum_{q \in \mu} \rho(q)
\]

and set \( m_i(M) := \rho_i^r |_M \) if \( i \neq 0 \), and \( m_0(M) \) in such a way that \( \sum_{i \geq 0} (2i + 1) m_i(M) = 4g - 4 + 2n \).

If \( M \in \mathcal{P}_{Q,Q'} \), then we define another function \( \tau_M \) as

\[
\tau_M : Q' \to \mathbb{N} \\
q \to \rho_{\mu_q}
\]

Definition 8.1. The combinatorial class with rational tails \( \overline{W}_{M,P}^r \) on \( \overline{\mathcal{M}}_{g,P \cup Q}^\text{comb} \) is the image through \( \vartheta^r_{M,P_{\text{comb}}} \) of the combinatorial class \( \overline{W}_{m^r + (M),\rho^r_M}^r \) (which lives on \( \overline{\mathcal{M}}_{g,P \cup I_M} \)). Clearly it is contained inside \( \delta^r_{M,P_{\text{comb}}} \).

Lemma 8.2. Let the notation be as before and let \( M \) be a partition in \( \mathcal{P}_{Q,Q'} \). Consider the forgetful map

\[
\pi_{Q'}^e : \overline{\mathcal{M}}_{g,P \cup Q}^\text{comb}(\mathbb{R}_+ \times \{0\}^Q) \setminus D_{Q',P}^\text{comb} \to \overline{\mathcal{M}}_{g,P \cup Q'}^\text{comb}(\mathbb{R}_+ \times \{0\}^Q')
\]
Then $\pi_Q^{\text{comb}}(W_{M,\rho,P}) = W_{m_*(M),\tau_M,P}$ and the restriction of $\pi_Q^{\text{comb}}$ to $W_{M,\rho,P}$ has degree
\[
\frac{(m_*(M) - m_*^T)!}{(m_0(M) - m_0^T)!}
\]
on its image.

**Proof.** Consider the following commutative diagram, where restrictions are understood and $\pi_{\text{comb}}$ forgets those markings $\iota_\mu$ such that $\mu \cap Q' = \emptyset$.

\[
\begin{array}{ccc}
W_{m_*(M),\rho | M,P} & \xrightarrow{\vartheta_{\text{comb}}^{rt}} & W_{m_*(M),\tau_M,P} \\
\downarrow{\pi_{\text{comb}}} & & \downarrow{\pi_{Q''}^{\text{comb}}} \\
W_{m_*(M),\rho | M,P} & \xrightarrow{\vartheta_{\text{comb}}^{rt}} & W_{m_*(M),\tau_M,P}
\end{array}
\]

As the restriction of $\vartheta_{\text{comb}}^{rt}$ has degree 1, we only need to compute the degree of the restriction of $\pi_{\text{comb}}$.

Consider vertices of valency $2i+3$ in the general simplex of $W_{m_*(M),\tau_M,P}$: among them, $m_i^T$ are marked by some elements of $Q'$ and $(m_i - m_i^T)$ are not. On the other side, the general simplex of $W_{m_*(M),\rho | M,P}$ has $m_i^T$ vertices marked by some elements of $I_M$. Thus, the cardinality of the fiber of $\pi_{\text{comb}}$ over a general simplex of $W_{m_*(M),\tau_M,P}$ is given by the product for every $i \geq 0$ of number of ordered $(m_i^T - m_i^T)$-uples in a set of $(m_i - m_i^T)$ elements. The claim follows because $m_i^T = m_i$ for all $i > 0$. \[\Box\]

Now we can state the main result.

**Theorem B.** Let $P = \{p_1, \ldots, p_n\}$ and $Q = \{q_1, \ldots, q_{s+u}\}$ and let be given $\rho : Q \rightarrow \mathbb{N}$ and $m_* = (0, m_0, m_1, \ldots)$ such that $m_i = m_i^\rho$ for $i > 0$ and $m_0 \geq m_0^\rho$. Then the following equation holds in $H_{6g-6+2n-2r}(\overline{\mathcal{M}}_{g,P,Q}, \partial C_Q)$
\[
\prod_{q \in Q} 2^{\rho(q)+1}(2\rho(q) + 1)!!(\psi^{\rho(q)+1})^* = W_{m_*,\rho,P} + \sum_{M \in \mathcal{P}_Q} c_M W_{M,\rho,P}^{rt}
\]

where $r = \sum_{i \geq 1} i m_i$ and the coefficient $c_M$ is defined as
\[
c_M := \prod_{\mu \in M} c_\mu \quad \text{and} \quad c_\mu = \frac{(2\rho_\mu + 2|\mu| - 1)!!}{(2\rho_\mu + 1)!!}.
\]

**Corollary B.1.** With the same notation as in the theorem, the following relation holds
\[
\left(\prod_{q \in Q} 2^{\rho(q)+1}(2\rho(q) + 1)!!\right) \prod_{q \in Q'} (\psi^{\rho(q)+1})^* \sum_{\sigma \in \mathcal{S}_Q} k_\sigma^* =
\]
Proof of Theorem B. Pick a closed PL differential form \( \omega \) on \( M \). Theorem B lifts to a subcomplex and decomposed into a sum of integrals on fibrations (which are restrictions of \( H_0^Q \)) and we get our result by using Faber’s formula (see Section 3) and Lemma 8.2.

Strategy. The proof of Theorem B basically follows that of Theorem A. To establish the asserted equality, we evaluate the integral

\[
\int_{\mathcal{M}_{g,P}^{\text{comb}}(\tilde{l})} (H_0^Q)^s(\eta) \wedge (H_0^{Q_u} \cdots H_0^{Q_1})^s(\xi_1^{q_1}+1) \wedge \cdots \wedge \xi_{q_u+u}^{q_u+1}
\]

where \([\eta] \in H^{6g-6+2n-2r}_{\mathcal{M}_{g,P}^{\text{comb}}}(\tilde{l}) \setminus D^{\text{comb}}_{Q,P}, \partial C^{Q_{u+1}}_{g,P} \setminus D^{\text{comb}}_{Q,P}\) with \( \tilde{l} \in C_{P,0} \) and \( \tilde{l} \) belongs to \( C_{P,s+u+1}^\ast \).

As in the proof of Theorem A, the integral is restricted to a certain subcomplex and decomposed into a sum of integrals on fibrations (which are restrictions of \( H_0^Q \)), so that we can integrate the \( \xi\)'s over the fibers of \( H_0^Q \). Each fiber consists of a cellular complex: the volume of a single cell (which is a product of simplices) is responsible of the factor in the left hand side, while \( c_M \) counts the number of maximal cells in the fiber.

Proof of Theorem B. Pick a closed PL differential form \( \eta \) of degree \( 6g-6+2n-2r \) on \( \mathcal{M}_{g,P}^{\text{comb}}(C_{P,0}) \setminus D^{\text{comb}}_{Q,P} \) that vanishes on \( \partial C^{Q_{u+1}}_{g,P} \setminus D^{\text{comb}}_{Q,P} \).

Consider then the forms \( \beta_i(\eta) \) on \( \mathcal{M}_{g,P}^{\text{comb}}(C_{P,i+1}^\ast) \setminus D^{\text{comb}}_{Q,P} \) defined as

\[
(\mathcal{H}_0^Q)^s(\eta) \wedge (\mathcal{H}_0^{Q_u} \cdots \mathcal{H}_0^{Q_1})^s(\xi_1^{q_1}+1) \wedge \cdots \wedge \xi_{q_u+u}^{q_u+1}
\]

for \( i = 1, \ldots, s+u \) and remember that \( \beta_{s+u}(\eta) \) extends by zero outside \( \mathcal{M}_{g,P}^{\text{comb}}(C_{P,s+u+1}^\ast) \setminus D^{\text{comb}}_{Q,P} \). As already mentioned in Section 5, the form \( \beta_{s+u}(1) \) has the property that its cohomology class pulls back via \( \tilde{\xi} \) to

\[
\psi_{q_1}^{q_1+1} \psi_{q_2}^{q_2+1} \cdots \psi_{q_u+u}^{q_u+1}
\]

on \( \mathcal{M}_{g,P} \times C_{P,s+u}^\ast \).
As in the proof of Theorem A, it is easy to see that the restriction of 
\( \beta_{s+u}(\eta) \) to \( \overline{M}_{g,P,\rho,Q}^{\text{comb}}(\tilde{l}) \) for some \( \tilde{l} \in C_{P,s+u}^{+} \) has support contained inside the locus \( \bigcup_{2\rho(q_{1})+3,\ldots,2\rho(q_{s+u})+3}^{+}(\tilde{l}) \) by reasons of degree. Now we want to analyze its image through \( \mathcal{H}_{0}^{Q} \) which consists of several components.

**Definition 8.3.** Given a ribbon graph, we say that two holes are **adjacent** if they have at least one vertex in common. Moreover, we say that a subset \( \mu \) of markings forms a **cluster** if

- every vertex of \( x(\mu) \) contains an edge that belongs to a hole in \( x(\mu) \)
- every two distinct holes in \( x(\mu) \) are joined by a chain of pairwise adjacent holes belonging to \( x(\mu) \).

Two clusters \( \mu \) and \( \mu' \) are **disjoint** if \( \mu \cup \mu' \) is not a cluster (in particular \( \mu \) and \( \mu' \) are disjoint as sets).

We associate to every partition \( M = \{ \mu_{1}, \ldots, \mu_{k} \} \) in \( P_{Q} \) the closure \( \overline{Y}_{M}(C_{P,s+u}^{+}) \) of the locus of top-dimensional simplices of \( \overline{Y}_{2\rho(q_{1})+3,\ldots,2\rho(q_{s+u})+3}^{+}(C_{P,s+u}^{+}) \) such that \( \mu_{1}, \ldots, \mu_{k} \) form disjoint clusters. It is obvious that \( \bigcup_{\mu} \overline{Y}_{M}(C_{P,s+u}^{+}) \) is a dissection of \( \overline{Y}_{2\rho(q_{1})+3,\ldots,2\rho(q_{s+u})+3}^{+}(C_{P,s+u}^{+}) \). Really, these subcomplexes overlap on simplices of nonmaximal dimension, but this fact is not important for what follows. Strictly speaking, we need a refinement of this dissection: for every tripartition \( M^{\bullet} = (M^{\text{disk}}, M^{\text{cyl}}, M^{\text{surf}}) \) of \( M \), we denote by \( \overline{Y}_{M^{\bullet}}(C_{P,s+u}^{+}) \) the closure of the locus in \( \overline{Y}_{M}(C_{P,s+u}^{+}) \) where the subsurface \( \bigcup_{\mu} \overline{T}_{\mu} \) form a disk (resp. a cylinder or a surface with negative Euler characteristic) for every cluster \( \mu \) in \( M^{\text{disk}} \) (resp. in \( M^{\text{cyl}} \) or in \( M^{\text{surf}} \)).

Then \( \mathcal{H}_{0}^{Q}(\overline{Y}_{M^{\bullet}}(C_{P,s+u}^{+})) \) is the smallest subcomplex of \( \overline{M}_{g,P,\rho,Q}^{\text{comb}}(C_{P,0}) \) containing all the simplices indexed by ribbon graphs \( G \) such that:

1. every \( \mu \in M^{\text{disk}} \) marks a nonpositive sphere that intersects only one positive component in a vertex of \( G \) of valency \( 2\rho_{\mu} + 3 \) (if \( \mu = \{ q_{j} \} \) we should simply say: \( q_{j} \) marks a vertex of \( G \) of valency \( 2\rho_{\mu} + 3 \), while all the other vertices in the smooth locus of \( G \) are trivalent)
2. every \( \mu \in M^{\text{cyl}} \) marks a nonpositive sphere that intersects the positive components in two vertices of \( G \) of valencies \( v_{1} \) and \( v_{2} \), with \( v_{1} + v_{2} = 2\rho_{\mu} \)
3. every \( \mu \in M^{\text{surf}} \) marks a nonpositive component of some genus \( h \) which intersects the positive components in \( \nu \) vertices of \( G \) of valencies \( v_{1}, \ldots, v_{\nu} \), provided \( 6h - 6 + \sum_{j=1}^{\nu} (v_{j} + 3) = 2\rho_{\mu} \).

Notice that \( \mathcal{H}_{0}^{Q}(\overline{Y}_{M^{\bullet}}(C_{P,s+u}^{+})) \) is contained inside \( \partial C_{g,P}^{Q,\text{comb}}(C_{P,0}) \) if \( M^{\text{cyl}} \) or \( M^{\text{surf}} \) are nonempty. Hence, we can restrict to \( M^{\text{cyl}} = M^{\text{surf}} = \emptyset \), in which case

\[
\mathcal{H}_{0}^{Q}(\overline{Y}_{M^{\bullet}}(C_{P,s+u}^{+})) = \begin{cases} 
\overline{W}_{m+\rho,P} & \text{if } M \text{ is discrete} \\
\overline{W}_{M,\rho,P} & \text{if } M \text{ is not discrete}.
\end{cases}
\]
The configuration of the $Q$-marked holes in the ribbon graphs $G$ that correspond to simplices of top dimension in $\overline{Y}_{(M, \emptyset, \emptyset)}$ is not so difficult to describe. We can restrict our analysis to a single cluster $\mu \in M$, because in $\overline{Y}_{(M, \emptyset, \emptyset)}$ they are disjoint.

We already know that the cluster $\mu$ has circular shape, that is $\bigcup_{q \in \mu} \overline{T}_q \subset S(G)$ is a disk. The fact that $\rho$ takes nonnegative values leads to a stronger conclusion.

**Lemma 8.4.** In the previous hypotheses, every $\overline{T}_q$ is a disk.

**Proof of Lemma 8.4.** By contradiction, suppose $h$ to be the minimum integer such that $q_h \in \mu$ and $\overline{T}_{q_h}$ is not a disk. Then it is a surface of genus zero with at least two boundary components. Moreover, if we remove $\overline{T}_{q_h}$, we disconnect the surface $S(G)$. Call $S_1, \ldots, S_f$ the connected components of $S(G) \setminus \overline{T}_{q_h}$ (which are necessarily disks) that do not contain $P$-markings. Call, for instance, $q_{i_1}, \ldots, q_{i_j}$ the marked points of $S_1$, with $i_1 < \cdots < i_j$.

One can see that $i_2 < h$ is impossible, because $\mathcal{H}_0^{q_h} \cdots \mathcal{H}_0^{q_{i_2}}$ sends $S_1$ to a genus zero component with a node and at least two marked points. A simple Euler characteristic computation shows that the holes in $S_1$ cannot have the right number of edges. In algebro-geometric terms, the equivalent assertion is that on $\overline{M}_{0,m+1}$ the class $\psi_1^{i_1} \cdots \psi_m^{i_j}$ vanishes if $t_1, \ldots, r_m \geq 1$, because $\dim_{\mathbb{C}} \overline{M}_{0,m+1} = m - 2$.

One can also exclude the case $i_1 < h < i_2$. In fact, the hole $\overline{T}_{q_{i_1}}$ is a disk (because $i_1 < h$) and $G$ has no univalent vertices, hence $\overline{T}_{q_{i_1}}$ does not contain internal edges. As a consequence, the hole $q_{i_1}$ has all its edges in common with $q_h, q_{i_2}, \ldots, q_{i_j}$, which is impossible.

A similar conclusion holds if we replace $S_1$ with any other component $S_2, \ldots, S_f$. Thus, the hole $q_h$ is collapsed after all the components $S_1, \ldots, S_f$. Hence, $\mathcal{H}_0^{q_{i_1}} \cdots \mathcal{H}_0^{q_{i_j}}$ shrinks $S_1, \ldots, S_f$ to nonpositive spheres that touch the rest of the surface in vertices of valency at least 3, because $\rho$ takes nonnegative values. Moreover, these vertices sit in the internal part of the hole $q_h$. On the other side, after the previous shrinking, the hole $\overline{T}_{q_h}$ has necessarily become a disk, and a disk that has internal edges must contain also an internal univalent vertex. Thus, we have found a contradiction. Hence, every $\overline{T}_{q_h}$ is a disk. \hfill $\square$

As it is evident, we have used in an essential way the hypothesis that $\rho$ takes nonnegative values.

**Remark.** A deeper inspection of the previous proof reveals more. Not only the map $\mathcal{H}_0^Q$ shrinks the cluster associated to $\mu$ to a vertex (if we do not care about nonpositive components), but also every partial shrinking $\mathcal{H}_0^{q_{i_1}} \cdots \mathcal{H}_0^{q_{i_j}}$ really sends the cluster associated to $\mu$ to a cluster with circular shape.

To integrate our differential form $\beta_{s+u}(\eta)$, we proceed as in the proof of Theorem A, shrinking one hole at a time. We choose positive lengths
$L'' < L', \varepsilon''_i < \varepsilon'_i$ for all $i = 1, \ldots, s + u - 1$ and $\varepsilon'_{s+u}$ in such a way that
\[
\sum_{j=i}^{s+u} \varepsilon'_j \ll \min\{\varepsilon''_{i-1}, \ldots, \varepsilon''_1, L'', \varepsilon'_{i-1} - \varepsilon''_{i-1}, \ldots, \varepsilon'_1 - \varepsilon''_1, L' - L''\}
\]
and we evaluate
\[
\int_{M_{s+u}} \psi_{\pi_1}^{\rho(q_1)+1} \cdots \psi_{\pi_{s+u}}^{\rho(q_{s+u})+1} \cdot (H^Q_0 \xi)^{\eta} =
\]
\[
= \lim_{\varepsilon''_{s+u} \to 0} \sum_{M \in \Psi_Q} \int_{\overline{Y}_M} \sum_{s+u}^{(l)} \beta_{s+u-1}(\eta) \wedge \lambda^*(d\tilde{p}_1 \wedge \cdots \wedge d\tilde{p}_{s+u-1})
\]
\[
= \sum_{M \in \Psi_Q} \int_{H^Q_0(\overline{Y}_M)} (L'' - L'')^n (\varepsilon''_1 - \varepsilon''_1) \cdots (\varepsilon''_{s+u-1} - \varepsilon''_{s+u-1}) \int_{\overline{F}_{s+u}} \eta^{\rho(q_{s+u})+1}
\]
where $F_{s+u}^{(l)}(\varepsilon''_{s+u})$ is the intersection of $\overline{Y}_M((L'', L')^n \times \cdots \times \{l\})$ with the generic fiber of $H^Q_0$ over $H^Q_0(\overline{Y}_M(L'', \ldots, \varepsilon'_{s+u-1}, 0))$. Moreover,
\[
\int_{\overline{F}_{s+u}^{(l)}} \eta^{\rho(q_{s+u})+1} = \frac{(\rho(q_{s+u}) + 1)!}{(2\rho(q_{s+u}) + 2)!} N_{s+u}^{s+u}
\]
where $N_{s+u}^{s+u}$ is the number of simplices of top dimension in $F_{s+u}^{(l)}(\varepsilon''_{s+u})$.

Then we let $\varepsilon''_{s+u-1}$ and $\varepsilon'_{s+u-1}$ go to zero, keeping their difference $\varepsilon''_{s+u-1} - \varepsilon''_{s+u-1}$ constant, so that the integral above is equal to
\[
\sum_{M \in \Psi_Q} \int_{H^Q_0(\overline{Y}_M)} (L'' - L'')^n (\varepsilon''_1 - \varepsilon''_1) \cdots (\varepsilon''_{s+u-2} - \varepsilon''_{s+u-2}) \beta_{s+u-2}(\eta) \wedge \lambda^*(d\tilde{p}_1 \wedge \cdots \wedge d\tilde{p}_{s+u-1})
\]
\[
= \left(\int_{\overline{Y}_M} \eta + \sum_{M \in \Psi_Q \cap M \text{ not discrete}} c_M \int_{M_{s+u}^{(l,0)}} \eta\right) \left(\int_{\overline{F}_{s+u}^{(l,0)}} \eta\right)
\]
where $l$ belongs to $[L'', L']^n$ and $c_M := N_{s+u}^{s+u}$ is the number of top-dimensional simplices contained in the intersection $F_{s+u}^{(l)}$ of $\overline{Y}_M((L'', L')^n \times \cdots \times \{l\})$ with the generic fiber of $H^Q_0$ over $H^Q_0(\overline{Y}_M((L'', L')^n \times \cdots \times \{l\})$. 

Now we are left to determine $c_M$. In order to reconstruct a ribbon graph $G$ parametrizing a maximal simplex in $F^1_M$ from its image through $\mathcal{H}_0^G$, it is sufficient to know the “configuration” of the clusters associated to $\mu_1, \ldots, \mu_k$. The key point is that this enumeration is “local”: we mean that we only use that each cluster is a disk and it is made of holes that keep their shape circular after each shrinking, and that these holes have the “right” number of edges. Briefly, we do not need to know about the surface apart from the clusters. Hence, if we denote by $c_{\mu_i}$ the number of possible configurations for the cluster $\mu_i$, then we can conclude that $F^1_M$ contains $c_M = c_{\mu_1} \cdots c_{\mu_k}$ maximal simplices.

Consequently, we need to determine the number $c_{\mu}$ of all possible “isomorphism types” of these clusters associated to $\mu$. More formally, by “isomorphism classes” of admissible clusters we mean isomorphism classes of ribbon graphs $G'$ such that:

- $G'$ is a connected ordinary ribbon graph marked by the set $\mu \cup \{0, v\}$
- $S(G')$ is a sphere and $\mu$ forms a cluster
- $\bar{T}_0$ is a disk and for every $q_j \in \mu$ the subsurface $\bar{T}_{q_j}$ is a disk
- for every $j = 2, \ldots, h$, the shrinking of the holes $q_{i_h}, q_{i_{h-1}}, \ldots, q_{i_j}$ produces a ribbon graph with only one positive component
- the vertices of $G'$ have valency two or three; the bivalent ones always border the hole 0 and one of them is marked by $v$
- if $\mu = \{q_{i_1}, \ldots, q_{i_h}\}$ with $i_1 < i_2 < \cdots < i_h$, then the hole $q_{i_h}$ has $2\rho(q_{i_h}) + 3$ sides, and for all $j = 1, \ldots, h-1$ the hole $q_{i_j}$ has $2\rho(q_{i_j}) + 3$ sides beside those which border the holes $q_{i_h}, \ldots, q_{i_{j+1}}$.
(Although we are only interested in the case $\rho(q_{i_1}) \geq 0$, we remark that the above definition and part of the subsequent calculation makes sense also for $\rho(q_{i_1}) = -1$.)

Given $G'_{\mu_1}, \ldots, G'_{\mu_k}$, we can reconstruct $G$ from $\mathcal{H}_0^G(G)$ in the following way. For every $\mu_i \in M$, we discard the nonpositive component associated to $\mu_i$ and we expand the corresponding $(2\rho_{\mu_i} + 3)$-valent vertex in order to obtain a polygon with $2\rho_{\mu_i} + 3$ edges bordering a new hole. Then we glue $G'_{\mu_i}$ to $G$ in such a way that the new hole of $G$ corresponds to the 0-th hole of $G'_{\mu_i}$ and the bivalent vertices of $G'_{\mu_i}$ are glued to the vertices of the polygon. The different $v$-markings on $G'_{\mu_i}$ count in how many ways we can perform this gluing.

So we are left to prove the following lemma.

**Lemma 8.5.** The number of isomorphism classes of admissible clusters associated to $\mu$ is

$$c_\mu = \frac{(2\rho_\mu + 2|\mu| - 1)!!}{(2\rho_\mu + 1)!!},$$

where we have conventionally set $(-1)!! = 1$.

**Proof of Lemma 8.5.** Remark that the calculation has a clear geometrical meaning even if we allow $\rho(q_{i_1})$ to assume the value $-1$.

Clearly, if $h = 1$ then $c_\mu = 1$. If $h > 1$, then the cluster has no rotational symmetries and so the possible $v$-markings are exactly $2\rho_\mu + 3$.

In particular, if $h = 2$ then the cluster consists of the holes $q_{i_1}$ with $2\rho(q_{i_1}) + 4$ sides and $q_{i_2}$ with $2\rho(q_{i_2}) + 3$ sides that have exactly one edge in common. Thus, in this case $c_\mu = 2\rho_\mu + 3$.

Now we deal with the case $h > 2$, so we suppose that the formula holds for all $|\mu| < h$, with $\rho(q_{i_1}) \geq -1$ and $\rho(q_{i_2}), \ldots, \rho(q_{i_h}) \geq 0$. We want to prove that the formula holds for $|\mu| = h$, with $\rho(q_{i_1}) \geq -1$ and $\rho(q_{i_2}), \ldots, \rho(q_{i_h}) \geq 0$.

If $\rho(q_{i_1}) = -1$, then we look at the situation just before shrinking $q_{i_1}$. We have a loop surrounding $q_{i_1}$ and its vertex has valency $2\rho_\mu + 5$. So this vertex is obtained collapsing the subcluster $\mu' = \mu \setminus \{q_{i_1}\}$. By induction hypothesis, $c_\mu$ is $(2\rho_\mu + 3)\rho_\mu' = (2\rho_\mu + 3)(2(\rho_\mu + 1) + 2(|\mu| - 1) - 1) \cdots (2(\rho_\mu + 1) + 3) = (2\rho_\mu + 3)(2\rho_\mu + 2|\mu| - 1) \cdots (2\rho_\mu + 5)$.

If $\rho(q_{i_1}) \geq 0$, then we look at the situation before collapsing $q_{i_2}$ and $q_{i_1}$. There are two possibilities: the holes may touch each other in one edge (case (a)) or in one vertex (case (b)). We want to show that in both cases the number of configurations (which we denote respectively by $c^a_\mu$ and $c^b_\mu$) depends only on $\rho(q_{i_1}) + \rho(q_{i_2})$ and not on $\rho(q_{i_1})$ and $\rho(q_{i_2})$ separately. Hence $c_\mu$ depends only on $\rho(q_{i_1}) + \rho(q_{i_2})$ too, because $c_\mu = c^a_\mu + c^b_\mu$. Henceforth, we can use the computation made for $\rho(q_{i_1}) = -1$ and we are done.

In case (a), the two holes $q_{i_1}$ and $q_{i_2}$ touch in one edge. Hence, the holes $q_{i_3}, \ldots, q_{i_h}$ are distributed in $t = (2\rho(q_{i_1}) + 3) + (2\rho(q_{i_2}) + 4) - 2 =$
$2(\rho(q_{i_1}) + \rho(q_{i_2})) + 5$ subclusters $\mu_1, \ldots, \mu_t$. Then we obtain

$$c_{\mu}^a = (2\rho_{\mu} + 3) \sum_{j \in J} \prod_{k=1}^t c_{j-1}(k)$$

where $J = \{ j : \mu \not\{q_{i_1}, q_{i_2}\} \to \{1, \ldots, t\} \}$ and conventionally $c_{\emptyset} = 1$, which depends only on $\rho(q_{i_1}) + \rho(q_{i_2})$ and not on $\rho(q_{i_1})$ and $\rho(q_{i_2})$ separately. In case (b), the two holes $q_{i_1}$ and $q_{i_2}$ touch in a vertex. Hence, we have

$$t = (2\rho(q_{i_1}) + 3) + (2\rho(q_{i_2}) + 3) - 1 = 2(\rho(q_{i_1}) + \rho(q_{i_2})) + 5$$

subclusters; but the cluster $\mu_1$, which corresponds to the common vertex, must be at least 4-valent. Moreover, the two holes can touch the cluster $\mu_1$ in $2\rho_{\mu_1}$ ways, hence we obtain

$$c_{\mu}^b = (2\rho_{\mu} + 3)(2\rho_{\mu_1}) \sum_{j \in J} \prod_{k=1}^t c_{j-1}(k)$$
where \( J = \{ j : \mu \setminus \{ q_{i_1}, q_{i_2} \} \to \{ 1, \ldots, t \} | \rho_{j-1}(1) \geq 1 \} \), which depends only on \( \rho(q_{i_1}) + \rho(q_{i_2}) \) and not on \( \rho(q_{i_1}) \) and \( \rho(q_{i_2}) \) separately.

**Example.** In the case \( \mu = \{ q_{i_1}, q_{i_2}, q_{i_3} \} \), the induction works as follows. If \( \rho(q_{i_1}) = -1 \) and \( \rho(q_{i_2}) = 1 \), we have that \( q_{i_2} \) and \( q_{i_3} \) touch in an edge. Then the hole \( q_{i_3} \) can be “attached” in \( 2\rho(q_{i_1}) + 2\rho(q_{i_2}) + 3 \) ways on the rest of the cluster (see Fig. 14). At the end, there are \( 2\rho(q_{i_2}) + 2\rho(q_{i_3}) + 1 \) bivalent vertices that can be marked by \( v \). Hence, there are \( (2\rho_{\mu} + 3)(2\rho_{\mu} + 5) \) total possibilities, and so in this case \( c_\mu = (2\rho_{\mu} + 5)(2\rho_{\mu} + 3) \).

If \( \rho(q_{i_1}) \geq 0 \), then we look at the cluster after the collapsing of \( q_{i_3} \).

In case (a) the two holes \( q_{i_1} \) and \( q_{i_2} \) touch in an edge and there are \( 2\rho(q_{i_1}) + 2\rho(q_{i_2}) + 5 \) vertices where the \( q_{i_3} \)-marking could be. So the number of total possibilities in case (a) is \( c^a_\mu = (2\rho_{\mu} + 3)(2\rho(q_{i_1}) + 2\rho(q_{i_2}) + 5) \), which correctly does not depend on \( \rho(q_{i_1}) \) and \( \rho(q_{i_2}) \) separately but only on \( \rho(q_{i_1}) + \rho(q_{i_2}) \).

In case (b) the two holes \( q_{i_1} \) and \( q_{i_2} \) touch in a vertex of valency at least 4, which is necessarily marked by \( q_{i_3} \) (and so this case may occur only if \( \rho(q_{i_3}) \geq 1 \)). It is easy to see that, before the shrinking, there were exactly \( 2\rho(q_{i_3}) \) distinct configurations in which \( q_{i_3} \) had one edge in common with \( q_{i_1} \) and one edge in common with \( q_{i_2} \), but \( q_{i_1} \) and \( q_{i_2} \) did not have edges in common (here we use that at the beginning vertices have valencies at most 3). Thus, in case (b) the number of possibilities is \( c^b_\mu = (2\rho_{\mu} + 3)(2\rho(q_{i_3})) \), which correctly vanishes if \( \rho(q_{i_3}) = 0 \) and which depends on \( \rho(q_{i_1}) + \rho(q_{i_2}) \) and not on \( \rho(q_{i_1}) \) and \( \rho(q_{i_2}) \) separately. Finally, there are \( c^a_\mu + c^b_\mu = (2\rho_{\mu} + 3)(2\rho_{\mu} + 5) \) total configurations.

As an application, we compute the case \( W_{2a+3,2b+3} \) of graphs with two vertices of valencies \( 2a + 3 \) and \( 2b + 3 \).

**Figure 14.** Example with \( h = 3 \), \( \rho(q_{i_1}) = -1 \), \( \rho(q_{i_2}) = 2 \) and \( \rho(q_{i_3}) = 1 \).
Corollary B.2. For every $g \geq 0$ and $P \neq \emptyset$ such that $2g - 2 + |P| > 0$ and for every $a, b \geq 1$, the following identity
\[
2^{\delta_{a,b}} W_{2a+3,2b+3} = 2^{a+b+2}(2a + 1)!!(2b + 1)!!(\kappa^*_a \kappa^*_b + \kappa^*_{a+b}) \\
- 2^{a+b+1}(2a + 2b + 3)!!\kappa^*_{a+b}
\]
holds in $H_{6g-6+2a-2b} (\overline{M}_{g,P}, \partial \mathcal{M}_{g,P})$.

Proof. It is a simple application of Theorem B. In fact, from the recursive formula one obtains
\[
2^{a+b+2}(2a + 1)!!(2b + 1)!!(\kappa^*_a \kappa^*_b + \kappa^*_{a+b}) = \\
= 2^{\delta_{a,b}} W_{2a+3,2b+3} + (2a + 2b + 3)W_{2a+2b+3} = \\
= 2^{\delta_{a,b}} W_{2a+3,2b+3} + (2a + 2b + 3)
\left[2^{a+b+1}(2a + 2b + 1)!!\kappa^*_{a+b}\right].
\]

\[\square\]

Appendix. On Looijenga’s modification of the arc complex

It is evident that a lot of technical problems come from the fact that we have not found a geometrical way to lift the combinatorial classes to the Deligne-Mumford compactification of the moduli space. In other words, we have not a triangulation of $\mathcal{M}_{g,P}$ that supports combinatorial classes.

In [Loo95], Looijenga defined a modification $\tilde{A}(S, P)$ of the arc complex that maps to $\overline{M}_{g,P}$. If $\tilde{A}(S, P)$ supported combinatorial cycles, then we could push their class forward to $\overline{M}_{g,P}$. The critical point is to prove that the combinatorial subcomplexes are really cycles. We are unable to do that in general, but we can handle the case of one nontrivalent vertex.

Here we sketch the construction of $\tilde{A}(S, P)$, but we refer to Looijenga’s paper for a more detailed treatment.

The modified arc complex. The notation being as in Section 2, let $Z \subset X_1(G)$ be a nonempty subset of edges of an ordinary connected ribbon graph $G$. We can construct two new ribbon graphs.

The subgraph $G_Z = (X(G_Z), \sigma_0', \sigma_1')$ has $X(G_Z)$ equal to the set of orientations of edges in $Z$, its $\sigma_1'$ is the natural restriction of $\sigma_1$, and its $\sigma_0'$ sends an oriented edge to the next one belonging to $X(G_Z)$ with respect to the cyclic order induced by $\sigma_0$. If $Z$ does not coincide with $X_1(G)$, then $G_Z$ has some new exceptional holes corresponding to orbits in $X(G_Z) \subset X(G)$ under $\sigma_0'$ which are not orbits under the action of $\sigma_\infty$.

Consider now a proper subset $Z$ of $X_1(G)$. Then the quotient graph $G/G_Z$ has $X(G/G_Z)$ equal to $X(G) \setminus X(G_Z)$, its $\sigma_1'$ is the restriction and its $\sigma_\infty'$ sends an oriented edge to the next one of $X(G/G_Z)$ with respect to the cyclic order induced by $\sigma_\infty$. If $Z$ is nonempty, then $G/G_Z$ has exceptional vertices corresponding to orbits in $X(G_Z) \subset X(G)$ under $\sigma_0'$ that are not orbits under the action of $\sigma_0$. 
Notice that there is a canonical correspondence between exceptional vertices of $G/G_Z$ and exceptional holes of $G_Z$ (see Fig. 15). In fact consider an exceptional hole $H$ of $G_Z$. For every (oriented) edge $e \in H$ call $c_e > 0$ the minimum integer such that $\sigma_1 \sigma_e^c (e)$ belongs to $H$. Then the subset $\{ \sigma_0^i (e) | e \in H \} \cap 0 < i < c_e$ is the corresponding exceptional vertex in $G/G_Z$. Conversely, given an exceptional vertex $V$ of $G/G_Z$ and an $e \in V$ call $c_e > 0$ the minimum integer such that $\sigma_e^c \sigma_1 (e)$ belongs to $V$. Then $\{ \sigma_e^i \sigma_1 (e) | e \in H \} \cap 0 < i < c_e$ is the corresponding exceptional hole in $G_Z$.

To introduce the definition of stable $P$-marked ribbon graph consider how an ordinary metrized $P$-marked ribbon graph $G$ can degenerate: it happens when the lengths of a subset $Z$ of edges go to zero. As we can work componentwise, we suppose $Z$ connected. Then various cases can occur:

1. $Z$ is a tree and contains at most one marked point, so it is contractible: then we can collapse it to a vertex and put, if necessary, the marking on it, that is we simply obtain $G/G_Z$.
2. $Z$ is homotopic to a circle and no vertex of $Z$ is marked, so we call it semistable. If $Z$ surrounds a single hole, then it shrinks to a vertex which inherits the marking in $G/G_Z$; otherwise $G/G_Z$ contains two exceptional vertices.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure15.png}
\caption{Example of correspondence between exceptional holes and exceptional vertices}
\end{figure}
(3) if $Z$ is neither contractible nor semistable, then its collapsing gives rise to a new irreducible component. If $Z$ contains no unmarked tails, then we call $Z$ a stable subset. Notice that every $Z$ which is not contractible or semistable contains a nonempty maximal stable subset $Z^\text{st}$. We denote by $G_{Z^\text{st}}$ the reduced ribbon graph obtained from $G_{Z}$ by “deleting” the bivalent unmarked vertices and we set $\overline{Z^\text{st}} = X_1(G_{Z^\text{st}})$.

Now we want to produce a stable version of ribbon graphs by successive collapsing of semistable or stable subsets of edges.

Given an ordinary connected $P$-marked ribbon graph $(G, x)$, we call $Z_\ast = (Z_0, Z_1, \ldots, Z_k)$ a permissible sequence for $(G, x)$ if $Z_0 = X_1(G)$ and $Z_{j+1} \subset \overline{Z_j^\text{st}}$ is a nonempty subset not containing a whole component of $\overline{Z_j^\text{st}}$ for every $j = 0, \ldots, k-1$. Given such a $Z_\ast$ we can produce a (quasi)stable $P$-marked ribbon graph taking the triple $(G(Z_\ast), \bar{x}, \iota)$ where

$$G(Z_\ast) := (G_{Z_0}/G_{Z_1}) \sqcup (G_{Z_1}/G_{Z_2}) \sqcup \cdots \sqcup (G_{Z_{k-1}}/G_{Z_k}) \sqcup G_{Z_k}^\text{st},$$

$\bar{x} : P \hookrightarrow X_\infty(G(Z_\ast)) \cup X_0(G(Z_\ast))$ is induced by $x$ and $\iota$ is a fixed-point-free involution that exchanges an exceptional hole and its corresponding exceptional vertex. The “stabilized” $P$-marked ribbon graph is simply obtained discarding possible unstable components, namely unmarked spheres with two exceptional holes, and making $\iota$ exchange the two corresponding exceptional vertices. In any case, $\iota$ never exchanges two holes.

We say that the (stable) components of $G_{Z_i}/G_{Z_{i+1}}$ have order $i$ and we define $H_i$ as the set of holes belonging to components of order $i$ and $V_i$ as the set of marked or exceptional vertices belonging to components of order $i$. Finally we say that $\Sigma := \sqcup_i (H_i \cup V_i)$ is the set of special points.

**Definition.** A stable metric with respect to $Z_\ast$ is a sequence of metrics $(a_i)_{i=0}^k$ where $a_0 \in \Delta_{\overline{Z_0}}$ and $a_i$ is a metric on $G_{Z_i}/G_{Z_{i+1}}$ which is positive of total length 1 on every irreducible component.

Thus, given a stable metric for $Z_\ast$, we can build a stable marked Riemann surface $S(G, Z_\ast, a_\ast)$. In fact we first consider the disjoint union of the surfaces $S(G_{Z_i}/G_{Z_{i+1}}, a_i)$ for $i = 0, \ldots, k$ and then we identify some pairs of points according to $\iota$. Remark that there is an extended circumference function

$$\hat{\Lambda} : \{\text{stable metrics on } S(G, Z_\ast)\} \rightarrow \prod_{i=0}^k \Delta_{H_i}$$

that restricts to a map $\hat{\Lambda}_0 : \{\text{stable metrics on } S(G, Z_\ast)\} \rightarrow \Delta_P$.

Now we can give the formal definition of stable $P$-marked ribbon graph.

**Definition.** Consider a metrized (possibly disconnected) ribbon graph $G$ with an injection $x : P \hookrightarrow \Sigma$ in a subset of “special points” $\Sigma \subset X_0(G) \cup X_\infty(G)$ such that $\Sigma \supset X_\infty(G)$, plus a fixed-point-free involution $\iota$ acting on
the set of “exceptional points” $\Sigma \setminus x(P)$. We say that an order function that assigns a natural number to each connected component of $G$ is admissible if

- components of order 0 contain at least one $P$-marked hole
- when $\iota$ exchanges all the elements of $\Sigma \setminus x(P)$ belonging to the component $G_j$ with elements belonging to components of order $\leq k$, then $G_j$ has order $\leq k + 1$
- every $h \in X_\infty(G) \setminus x(P)$ belongs to a component of order $k > 0$ and the point $\iota(h)$ sits in a component of order at most $k - 1$ (and so is a vertex).

We call $(G, x, \iota)$ a $P$-marked stable ribbon graph if there exists an admissible order function on $G$. A stable metric on $(G, x, \iota)$ is the datum of a positive metric $a_j$ of total length 1 for every connected component $G_j$.

Now let $\alpha$ be a proper simplex of $A$ whose associated marked ribbon graph is $G_\alpha$. Consider the set $Z(G_\alpha)$ of connected stable subsets of $X_1(G_\alpha)$ and for every $Z \in Z(G_\alpha)$ let $|\alpha| \to \Delta_Z \to \Delta_Z^\infty$ be the natural map that projects first to a face and then to the space of metrics of the reduced ribbon graph $G_Z$. Define $\hat{\alpha}$ to be the closure of the graph of the map $|\alpha| \hookrightarrow |\alpha| \times \prod_{Z \in Z(G_\alpha)} \Delta_Z^\infty$ in $|\alpha| \times \prod \Delta_Z^\infty$.

It can be proven that $\hat{\alpha}$ parametrizes all stable degenerations of the ribbon graph $G_\alpha$. Moreover, all the $\hat{\alpha}$’s can be glued to obtain a modification $\hat{A}$ of the arc complex. Remark that $\hat{A}(S, P)$ comes with an obvious cellularization indexed by permissible sequences: for every $Z_\bullet = (Z_0, \ldots, Z_k)$ there is a (closed) cell isomorphic to $|\alpha_0| \times \cdots \times |\alpha_k|$ that parametrizes stable metrics on $G(Z_\bullet)$. The projections $|\alpha_0| \times \cdots \times |\alpha_k| \to |\alpha_0|$ glue to give a continuous surjection $\hat{A}(S, P) \to |A(S, P)|$ which is actually a quotient (i.e. $|A(S, P)|$ has the quotient topology).

We may regard the map $\hat{A}(S, P)/\Gamma_{S,P} \to |A(S, P)|/\Gamma_{S,P}$ as a sort of real oriented blow-up along a subcomplex, which is in fact the locus on which $\hat{M}_{g,P} \times \Delta_P \to |A(S, P)|/\Gamma_{S,P}$ is not a homeomorphism.

**Theorem** ([Loo95]). The modular group $\Gamma_{g,P}$ naturally acts on $\hat{A}(S, P)$ respecting the cellularization. The product of the classifying map $\hat{A}(S, P)/\Gamma_{S,P} \to \hat{M}_{g,P}$ with $\hat{\lambda}$ is a continuous surjection

$$\hat{\Phi} : \hat{A}(S, P)/\Gamma_{S,P} \to \hat{M}_{g,P} \times \Delta_P$$

that extends $\Phi$, so it is one-to-one when restricted to the dense open subset $|A^\circ(S, P)|/\Gamma_{S,P}$.

We still denote by $\hat{\Phi}$ the map $\hat{\Phi} : \hat{M}_{g,P}^{\text{comp}} \to \hat{M}_{g,P} \times (\mathbb{R}_P^1 \setminus \{0\})$. 

where \( \hat{\mathcal{M}}_{g,P}^{\text{comb}} := (\hat{\mathcal{A}}(S, P)/\Gamma_{S,P}) \times \mathbb{R}_+. \)

Finally, the following commutative diagram

\[
\begin{array}{ccc}
\hat{\mathcal{M}}_{g,P}^{\text{comb}} & \xrightarrow{\hat{\Phi}} & \hat{\mathcal{M}}_{g,P} \times (\mathbb{R}_0 \setminus \{0\}) \\
\downarrow & & \downarrow \xi \\
|A(S, P)|/\Gamma_{S,P} \times \mathbb{R}_+ & \xrightarrow{\overline{\Phi}} & \mathcal{M}_{g,P}^{\triangle} \times \mathbb{R}_+ 
\end{array}
\]

shows that \( \overline{\Phi} \) is a homeomorphism, because it is bijective and proper and both the vertical arrows are quotients.

**Combinatorial classes on \( \hat{\mathcal{M}}_{g,P}^{\text{comb}} \).** As the space \( \mathcal{M}_{g,P}^{\text{comb}} \) includes in \( \hat{\mathcal{M}}_{g,P}^{\text{comb}} \), we can define \( \hat{W}_{m_*, P} \) as the closure of \( W_{m_*, P} \) inside \( \hat{\mathcal{M}}_{g,P}^{\text{comb}} \) (similarly for \( \hat{W}_{m_*, \rho, P} \) and \( W_{m_*, \rho, P} \)).

Notice that the map \( \hat{\mathcal{M}}_{g,P}^{\text{comb}} \to \mathcal{M}_{g,P}^{\text{comb}} \) sends \( \hat{W}_{m_*, P} \) onto \( W_{m_*, P} \) with degree 1. Hence, if \( \hat{W}_{m_*, P}(l) \) were a cycle, then its image in \( \mathcal{M}_{g,P} \) would be a lift of \( W_{m_*, P}(l) \). We can weaken this requirement: if the image at the level of chains \( \hat{\Phi}_t(\hat{W}_{m_*, P}) \) were a cycle in \( \mathcal{M}_{g,P} \), then it would be a lift of \( \hat{W}_{m_*, P} \).

Anyway, the situation is not so simple as for \( W_{m_*, P} \). In fact, if we consider a simplex \( \alpha \) in \( |A(S, P)| \), then \( \partial \alpha \) is made of simplices corresponding to ribbon graphs that are obtained from \( G_\alpha \) by contracting one edge. On the contrary, if we consider \( \hat{\alpha} \) in \( \hat{A}(S, P) \), then we may obtain a simplex in \( \partial \hat{\alpha} \) by collapsing a stable subgraph \( Z \) (for instance, look at Fig. 16, where a cell of real codimension one in the boundary of \( \hat{W}_q \) is obtained collapsing the subgraph \( Z \) of the edges sitting in the grey zone).

As an example, we analyze the case \( \hat{W}_{2r+3}^q \). The situation is quite simpler than in the general case, because the only new cells of real codimension one occurring in the topological boundary \( \partial \hat{W}_{2r+3}^q \) are indexed by ribbon graphs that are very similar to the ribbon graph of Fig. 16. In fact, let \( \hat{\beta} \) be a cell in \( \partial \hat{W}_{2r+3}^q \). The associated ribbon graph \( G_{\hat{\beta}} \) must have one positive component \( G^+_\hat{\beta} \) and one nonpositive component \( G^-_{\hat{\beta}} \). Moreover, we can consider only the case in which \( G^0_{\hat{\beta}} \) has one exceptional hole. In fact, if \( G^0_{\hat{\beta}} \) had more exceptional holes, then \( \hat{\Phi}(\hat{\beta}) \) would have one dimension less than \( \hat{\beta} \) and so it would give no contribution to \( \partial \hat{\Phi}_t(\hat{W}_{2r+3}^q) \). Notice that, because of this hypothesis, the \((2r + 3)\)-valent vertex has split into the exceptional vertex \((f_1, \ldots, f_{v_{ex}})\) of \( G^+_{\hat{\beta}} \) and the \( q \)-marked vertex \((e_1, \ldots, e_{v_q})\) in \( G^0_{\hat{\beta}} \).
Consider a cell $\hat{\alpha} \in \hat{W}_q^{2r+3}$ such that $\hat{\beta} \in \partial \hat{\alpha}$. Then, the $q$-marked vertex in $G_{\hat{\alpha}}$ looks like

$$(e_i, f_1, \ldots, f_{t_1-1}, e_{i+1}, f_{t_1}, \ldots, f_{t_2-1}, e_{i+2}, \ldots, e_{i-1}, f_{t_2(vq-1)+1}, \ldots, f_{vex}).$$

Now we define two operators that permute cells in $\hat{W}_q^{2r+3}$ that have $\hat{\beta}$ in their boundary. The first operator $R_{ex}$ sends the $\hat{\alpha}$ above to the cell $R_{ex}(\hat{\alpha})$ with $q$-marked vertex

$$(e_i, f'_1, \ldots, f'_{t_1-1}, e_{i+1}, f'_{t_1}, \ldots, f'_{t_2-1}, e_{i+2}, \ldots, e_{i-1}, f'_{t_2(vq-1)+1}, \ldots, f'_{vex})$$

where $f'_j = f_{j+1}$ for $j = 1, \ldots, vex - 1$ and $f'_{vex} = f_1$. The second operator $R_q$ sends the $\hat{\alpha}$ above to the cell $R_q(\hat{\alpha})$ with $q$-marked vertex

$$(e'_i, f_1, \ldots, f_{t_1-1}, e'_{i+1}, f_{t_1}, \ldots, f'_{t_2-1}, e_{i+2}, \ldots, e_{i-1}, f'_{t_2(vq-1)+1}, \ldots, f_{vex})$$

where $e'_i = e_{i+1}$ for $i = 1, \ldots, vq - 1$ and $e'_{vq} = e_{i+1}$.

Now, suppose that $v_q$ is even (otherwise, exchange the role of $(v_q, R_q)$ and $(v_{ex}, R_{ex})$). If we prove that $\hat{\alpha}$ and $R_q(\hat{\alpha})$ induce opposite orientations on $\hat{\beta}$, then we obtain that terms $\hat{\beta}$ in $\partial \hat{W}_q^{2r+3}$ sum up to zero.

To do that, we use the formalism of Conant and Vogtmann (see [CV03]).
They proved that, for any connected ribbon graph \( G \),
\[
\det(H_1(|G|)) \otimes \det(\mathbb{R} X_1(G)) \cong \bigotimes_{V \in X_0(G)} \det(\mathbb{R} V) \otimes \det(\bigoplus_{|V| \text{even}} \mathbb{R})
\]
while for a disconnected ribbon graph \( G \) one has to choose an ordering of the connected components. In our case, we can order the connected components of the ribbon graph \( G_{\hat{\beta}} \) by prescribing that the even vertex sits in the first component; the sign produced by this choice cancels up with the standard choice in \( \det(\bigoplus_{|V| \text{even}} \mathbb{R}) \) given by the unique even vertex.

Moreover, one can easily verify that the map \( |G_0^0_{\hat{\beta}}| \cup |G_0^+_{\hat{\beta}}| \longrightarrow |G_{\hat{\alpha}}| \) that glues the \( q \)-marked vertex and the exceptional vertex induces the following isomorphism
\[
H_1(|G_0^0_{\hat{\beta}}|) \oplus H_1(|G_0^+_{\hat{\beta}}|) \cong H_1(|G_{\hat{\alpha}}|).
\]

Hence, the ratio between the orientations on \( \hat{\beta} \) induced by \( \hat{\alpha} \) and \( R_q(\hat{\alpha}) \) is easily seen to be \((-1)^{v_{ex}} = -1\) and so we have proven the following.

**Proposition.** For every \( r \geq 0 \) and every \( \tilde{l} = (l, 0) \in \mathbb{R}_+^P \times \{0\} \), the subcomplex \( \tilde{\mathcal{W}}_{2r+3}^q \subset \tilde{\mathcal{M}}_{g,P \cup \{q\}}^{\text{comb}} \) pushes forward to a cycle
\[
\bar{\Phi}_{\tilde{l}}(\tilde{\mathcal{W}}_{2r+3}^q) \in H_{6g-6+2n-2r}(\tilde{\mathcal{M}}_{g,P \cup \{q\}})
\]
which is a lifting of \( \mathcal{W}_{2r+3}^q \). As a consequence, for every \( r \geq 0 \), the cycle
\[
(\pi_q \bar{\Phi}_{\tilde{l}})_*(\tilde{\mathcal{W}}_{2r+3}^q) \in H_{6g-6+2n-2r}(\tilde{\mathcal{M}}_{g,P})
\]
is a lifting of \( \mathcal{W}_{2r+3} \).
