Abstract. In the present paper, we have studied curvature tensors of a quasi-Sasakian manifold with respect to the $D_a$-homothetic deformation. We have deduced the Ricci soliton in quasi-Sasakian manifold with respect to the $D_a$-homothetic deformation. We have also proved that the quasi-Sasakian manifold is not $\xi$-projectively flat under $D_a$-homothetic deformation. Also, we give an example to prove the existance of quasi-Sasakian manifold.

Key words: Quasi-Sasakian manifold, $D_a$-homothetic deformation, Ricci soliton, Weyl projective curvature tensor.

1. Introduction

In 1967, D. E. Blair [1] introduced the notion of quasi-Sasakian structure to unify Sasakian and cosymplectic structures. The Riemannian curvature tensor of three dimensional quasi-Sasakian manifold is given by [10]

$$R(X, Y)Z = g(Y, Z)[(r^2 - \beta^2)X + (3\beta^2 - \frac{r^2}{2})\eta(X)\xi + \eta(X)(\phi \text{grad} \beta) - d\beta(\phi X)\xi - g(X, Z)\eta(Y)\xi + \eta(Y)(\phi \text{grad} \beta) - d\beta(\phi Y)\xi + \eta(Z)d\beta(\phi Y)]X + \eta(Y)\eta(Z) - \eta(Y)d\beta(\phi Z) - \eta(Z)d\beta(\phi Y)]X \eta(Y) - \eta(Y)d\beta(\phi Z) - \eta(Z)d\beta(\phi Y)].X$$

\[
- \left[ \frac{r}{2} - \beta^2 \right] g(X, Z) + (3\beta^2 - \frac{r}{2}) \eta(X)\eta(Z) - \eta(X)d\beta(\phi Z) \\
- \left( \eta(Z)d\beta(\phi X) \right) Y - \frac{r}{2} [g(Y, Z)X - g(X, Z)Y],
\]

where \( \beta \) is a function on the manifold. In the paper [2], U. C. De and A. K. Mondal have proved that \( \xi \beta = 0 \). In a quasi-Sasakian manifold, if we consider \( \beta \) is a non-zero constant, then the manifold becomes \( \beta \)-Sasakian and if \( \beta = 1 \), the manifold becomes a Sasakian manifold.

The notion of \( D_{\alpha} \)-homothetic deformation was introduced by Tanno [11] in 1968. In paper [8], H. G. Nagaraja, D. L. Kiran Kumar and D. G. Prakash have studied \( D_{\alpha} \)-homothetic deformation of \((\kappa, \mu)\)-contact metric manifolds. Nagaraja and Premalatha have studied \( D_{\alpha} \)-homothetic deformation of \( K \)-contact manifolds in the paper [9].

Ricci soliton was introduced by Hamilton [4] which is the generalization of the Einstein metrics and is defined by

\[
(L_X g)(Y, Z) + 2S(Y, Z) + 2\lambda g(Y, Z) = 0,
\]

where, \( L_X \) denotes the Lie-derivatives of Riemannian metric \( g \) along the vector field \( X \), \( \lambda \) is a constant, \( S \) the Ricci tensor of type \((0, 2)\) and \( Y, Z \) are arbitrary vector fields on the manifold. A Ricci soliton is called shrinking or steady or expanding according as \( \lambda \) is negative or zero or positive. Ricci solitons on three dimensional almost contact manifolds have been studied by several authors. For instance, U. C. De and A. K. Mondal studied Ricci solitons on three dimensional quasi-Sasakian manifolds [2]. S. K. Hui and collaborators have investigated Ricci solitons and their generalizations on some classes of almost contact manifolds. For details see [5], [6], [7].

In this paper we would like to study some properties of quasi-Sasakian manifold with \( D_{\alpha} \)-homothetic deformation.

The paper is organized as follows: In Section 2, we have discussed some preliminaries. In Section 3, we give an example of quasi-Sasakian manifold to prove the existence of the said manifold. In Section 4, we deduced some curvature properties of quasi-Sasakian manifold with respect to the \( D_{\alpha} \)-homothetic deformation. In Section 5, we study the Ricci soliton in quasi-Sasakian manifold with respect to the \( D_{\alpha} \)-homothetic deformation. In the last Section, we have derived the \( \xi \)-projective curvature tensor under \( D_{\alpha} \)-homothetic deformation.

2. Preliminaries

Let \( M \) be a \((2n + 1)\)-dimensional manifold endowed with an almost contact metric structure \((\phi, \xi, \eta, g)\), where \( \phi \) is a tensor field of type \((1, 1)\), \( \xi \) is a vector
DΦ-homothetic deformation and Ricci solitons

field, η is a 1-form and g is the Riemannian metric on M such that [10]

$$\phi^2(X) = -X + \eta(X)\xi, \quad \eta(\xi) = 1.$$  

As a consequence, we get the following:

$$\phi \xi = 0, \quad g(X, \xi) = \eta(X), \quad \eta(\phi X) = 0,$$
$$g(\phi X, \phi Y) = g(X, Y) - \eta(X)\eta(Y),$$
$$g(\phi X, Y) = -g(X, \phi Y), \quad g(\phi X, X) = 0,$$
$$\langle \nabla_X \eta \rangle(Y) = g(\nabla_X \xi, Y),$$

for all vector fields X, Y on (M)

Let Φ be the fundamental 2-form of M defined by

$$\Phi(X, Y) = g(X, \phi Y),$$

for all X, Y on M. M is said to be quasi-Sasakian if the almost contact structure

(φ, ξ, η, g) is normal and the fundamental 2-form Φ is closed i.e., dΦ = 0 [1]. The

normality condition gives that the induced almost complex structure of M × R is

integrable or equivalently, the torsion tensor field N = [φ, φ] + 2ξ ⊗ dη vanishes iden-

tically on M, where [X, Y] is the Lie bracket. The rank of a quasi-Sasakian structure

is always an odd integer [1] which is equal to 1 if the structure is cosymplectic and

it is equal to (2n + 1) if the structure is Sasakian.

For a three-dimensional quasi-Sasakian manifold, we have [2]

\begin{align}
(\nabla_X \xi) & = -\beta \phi X, \\
(\nabla_X \phi)(Y) & = \beta(g(X, Y)\xi - \eta(Y)X), \\
(\nabla_X \eta)(Y) & = -\beta g(\phi X, Y), \\
R(X, Y)\xi & = -(X\beta)\phi Y + (Y\beta)\phi X + \beta^2\{\eta(Y)X - \eta(X)Y\}, \\
S(X, Y) & = \left(\frac{r}{2} - \beta^2\right)g(X, Y) + (3\beta^2 - \frac{r}{2})\eta(X)\eta(Y) \\
& \quad - \eta(X)d\beta(\phi Y) - \eta(Y)d\beta(\phi X), \\
QX & = \left(\frac{r}{2} - \beta^2\right)X + (3\beta^2 - \frac{r}{2})\eta(X)\xi \\
& \quad - \eta(X)(\phi \text{grad} \beta) - d\beta(\phi X)\xi, \\
S(X, \xi) & = 2\beta^2\eta(X) - d\beta(\phi X). 
\end{align}

The Weyl projective curvature tensor P of type (1, 3) on a Riemannian manifold

(M, g) of dimension (2n + 1) is defined by [3]

$$P(X, Y)Z = R(X, Y)Z - \frac{1}{2n}[S(Y, Z)X - S(X, Z)Y],$$

for all X, Y, Z ∈ χ(M).
3. Example of quasi-Sasakian manifold of dimension three

This example is constructed by following U. C. De and A. K. Mondal in the paper [2].

Let us consider the manifold $M = \{x_1, x_2, x_3 \in \mathbb{R}^3 : x_3 \neq 0\}$ of dimension 3, where $\{x_1, x_2, x_3\}$ are standard co-ordinates in $\mathbb{R}^3$. We choose the vector fields

$$ e_1 = \frac{\partial}{\partial x_1}, \quad e_2 = \frac{\partial}{\partial x_2} + x_1 \frac{\partial}{\partial x_3}, \quad e_3 = \frac{\partial}{\partial x_3}, $$

which are linearly independent at each point of $M$, we get

$$ [e_1, e_2] = e_3, \quad [e_1, e_3] = 0, \quad [e_2, e_3] = 0. $$

Let $g$ be the Riemannian metric defined by $g(e_i, e_j) = \delta_{ij}$, for all $i, j = 1, 2, 3$. Let $\nabla$ be the Riemannian connection and $R$ the curvature tensor of $g$. The 1-form $\eta$ is defined by $\eta(X) = g(X, e_3)$, for any $X$ on $M$, which is a contact form because $\eta \wedge d\eta \neq 0$.

Let $\phi$ be the $(1, 1)$-tensor field defined by

$$ \phi(e_1) = e_2, \quad \phi(e_2) = -e_1, \quad \phi(e_3) = 0. $$

Then we find

$$ \eta(e_3) = 1, \quad \phi^2 X = -X + \eta(X)e_3, $$

$$ g(\phi X, \phi Y) = g(X, Y) - \eta(X)\eta(Y), $$

for any vector fields $X, Y$ on $M$. Hence $(\phi, e_3, \eta, g)$ defines an almost contact metric structure on $M$.

Using Koszul’s formula, we obtain

$$ \nabla_{e_1} e_2 = \frac{1}{2} e_3, \quad \nabla_{e_1} e_3 = -\frac{1}{2} e_2, \quad \nabla_{e_2} e_3 = \frac{1}{2} e_1, $$

$$ \nabla_{e_2} e_1 = -\frac{1}{2} e_3, \quad \nabla_{e_3} e_1 = -\frac{1}{2} e_2, \quad \nabla_{e_3} e_2 = \frac{1}{2} e_1 $$

and the remaining $\nabla_{e_i} e_j = 0$, for all $i, j = 1, 2, 3$. Thus we see that the structure $(\phi, e_3, \eta, g)$ satisfies the formula $\nabla_X e_3 = -\beta \phi X$ for $\beta = -\frac{1}{2}$.

Hence the manifold is a three dimensional quasi-Sasakian manifold with the constant structure function $\beta$. 
Also, from the definition of curvature tensor, the expressions curvature tensor are given by

\[
R(e_1, e_2)e_1 = \frac{3}{4}e_2, \quad R(e_1, e_2)e_2 = -\frac{3}{4}e_1, \quad R(e_1, e_3)e_1 = -\frac{1}{4}e_3,
\]

\[
R(e_2, e_3)e_3 = \frac{1}{4}e_2, \quad R(e_1, e_3)e_3 = \frac{1}{4}e_1, \quad R(e_2, e_3)e_2 = -\frac{1}{4}e_3
\]

and the remaining \( R(e_i, e_j)e_k = 0 \), for all \( i, j, k = 1, 2, 3 \).

4. \( D_a \)-homothetic deformation

Let \((M, \phi, \xi, \eta, g)\) be a 3-dimensional quasi-Sasakian manifold. A \( D_a \)-homothetic deformation is defined by

\[
(4.1) \quad \tilde{\phi} = \phi, \quad \tilde{\xi} = \frac{1}{a}\xi, \quad \tilde{\eta} = a\eta, \quad \tilde{g} = ag + a(a-1)\eta \otimes \eta,
\]

with \( a \) being a positive constant [8].

If \((M, \phi, \xi, \eta, g)\) is a quasi-Sasakian manifold with Riemannian connection \( \nabla \) and \( \tilde{\nabla} \) be the connection of the \( D_a \)-homothetic deformed quasi-Sasakian manifold \((M, \tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})\) which is calculated from \( \nabla \) and \( g \). Then the relation between the connections \( \nabla \) and \( \tilde{\nabla} \) is given by

\[
(4.2) \quad \tilde{\nabla}_X Y = \nabla_X Y + (1-a)[\eta(Y)\phi X + \eta(X)\phi Y],
\]

for any vector fields \( X, Y \), on \( M \).

The Riemannian curvature tensor \( \hat{R} \) of \((M, \tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})\) is given by

\[
(4.3) \quad \hat{R}(X, Y)Z = \nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z - \nabla_{[X, Y]} Z.
\]

Using (2.1), (2.2), (4.1) and (4.2) in (4.3), we get

\[
\hat{R}(X, Y)Z = R(X, Y)Z + (1-a)\beta[g(X, Z)\eta(Y)\xi - g(Y, Z)\eta(X)\xi - 2g(\phi X, Y)\phi Z - g(\phi X, Z)\phi Y + g(\phi Y, Z)\phi Z + 2\eta(Y)\eta(X)Z + 2\eta(X)\eta(Z)Y] - (1-a)^2[\eta(X)\eta(Z)Y - \eta(Y)\eta(Z)X].
\]

Therefore,

\[
\hat{R}(X, Y, Z, W) = R(X, Y, Z, W) + (1-a)\beta[g(X, Z)\eta(Y)\eta(W) - g(Y, Z)\eta(X)\eta(W) - 2g(\phi X, Y)g(\phi Z, W) - g(\phi X, Z)g(\phi Y, W) + g(\phi Y, Z)g(\phi X, W) - 2g(X, W)\eta(Y)\eta(Z) + 2g(Y, W)\eta(X)\eta(Z)] - (1-a)^2[g(Y, W)\eta(X)\eta(Z) - g(X, W)\eta(Y)\eta(Z)],
\]
where $\tilde{R}(X, Y, Z, W) = g(\tilde{R}(X, Y)Z, W)$ and $R(X, Y, Z, W) = g(R(X, Y)Z, W)$.

Let, $\{e_i\}, (i = 1, 2, 3)$ be the orthonormal basis of the tangent space of the manifold. Putting $X = W = e_i$, in (4.5) and summing over $i$, we get

$$\tilde{S}(Y, Z) = S(Y, Z) + 2(1 - a)\beta[g(Y, Z) - 3\eta(Y)\eta(Z)] + 2(1 - a)^2\eta(Y)\eta(Z).$$

From which,

$$\tilde{Q}Y = QY + 2(1 - a)\beta(Y - 3\eta(Y)\xi) + 2(1 - a)^2\eta(Y)\xi,$$

From (2.2) and (4.2), we get

$$(\tilde{\nabla}_X \phi)Y = (\nabla_X \phi)Y - (1 - a)\eta(Y)\phi^2 X.$$

Also, from (2.1) and (4.2), we obtain

$$(\tilde{\nabla}_X \tilde{\xi}) = \frac{1 - a - \beta}{a} \phi X.$$

Thus, from (2.3), (4.1), (4.2) and (4.7), we get

$$(\tilde{\nabla}_X \tilde{\eta})Y = a^2(1 - a - \beta)g(\phi X, Y).$$

Thus, we can state the following

**Theorem 4.1.** For a $D_a$-homothetically deformed quasi-Sasakian manifold $M(\tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})$, the followings hold

$$\tilde{R}(X, Y, Z, W) = R(X, Y, Z) + (1 - a)\beta[g(X, Y)Z, W] - g(Y, Z)\eta(X)\xi - 2g(\phi X, Y)\phi Z - g(\phi X, Z)\phi Y + g(\phi Y, Z)\phi X - 2\eta(Y)\eta(\phi Y)X + 2\eta(X)\eta(Z)Y - (1 - a)^2[\eta(X)\eta(Z)Y - \eta(Y)\eta(Z)X].$$

$$\tilde{S}(Y, Z) = S(Y, Z) + 2(1 - a)\beta[g(Y, Z) - 3\eta(Y)\eta(Z)] + 2(1 - a)^2\eta(Y)\eta(Z).$$

$$\tilde{Q}Y = QY + 2(1 - a)\beta(Y - 3\eta(Y)\xi) + 2(1 - a)^2\eta(Y)\xi,$$

$$(\tilde{\nabla}_X \phi)Y = (\nabla_X \phi)Y - (1 - a)\eta(Y)\phi^2 X.$$

$$\tilde{\nabla}_X \tilde{\xi} = \frac{1 - a - \beta}{a} \phi X.$$

$$(\tilde{\nabla}_X \tilde{\eta})Y = a^2(1 - a - \beta)g(\phi X, Y).$$
5. Ricci soliton in three dimensional quasi-Sasakian manifold with respect to the $D_a$-homothetic deformation

Let $M(\tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})$ be a $D_a$-homothetically deformed quasi-Sasakian manifold of dimension 3. A Ricci soliton $(\tilde{g}, V, \lambda)$ is defined on $M(\tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})$ as

\begin{equation}
(\tilde{L}_V \tilde{g})(X, Y) + 2\tilde{S}(X, Y) + 2\lambda \tilde{g}(X, Y) = 0,
\end{equation}

where $\tilde{L}_V \tilde{g}$ denotes the Lie derivative of Riemannian metric $\tilde{g}$ along a vector field $V$, $\tilde{S}$ is the Ricci tensor of type $(0, 2)$ on $M(\tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})$.

Let us suppose that the vector field $V$ is the Reeb vector field $\tilde{\xi}$ on $M(\tilde{\phi}, \tilde{\xi}, \tilde{\eta}, \tilde{g})$. Then from (5.1), we have

\begin{equation}
(\tilde{L}_{\tilde{\xi}} \tilde{g})(X, Y) + 2\tilde{S}(X, Y) + 2\lambda \tilde{g}(X, Y) = 0.
\end{equation}

Now, from (2.1) and (4.2), we have

\begin{equation}
(\tilde{L}_{\tilde{\xi}} \tilde{g})(X, Y) = \tilde{g}(\nabla_X \tilde{\xi}, Y) + \tilde{g}(X, \nabla_Y \tilde{\xi}) = 0.
\end{equation}

Therefore, from (4.1), (5.2) and (5.3), we get

\begin{equation}
\tilde{S}(X, Y) = -\lambda \tilde{g}(X, Y).
\end{equation}

Putting $Y = Z = \xi$ in (4.6), we get

\begin{equation}
\tilde{S}(\xi, \xi) = 2(\beta + a - 1)^2.
\end{equation}

Putting $X = Y = \tilde{\xi}$ in (5.4) and using (5.5), we get

\[ \lambda = -\frac{2(\beta + a - 1)^2}{a^2}. \]

Thus we can state the following

**Theorem 5.1.** If a $D_a$-homothetically deformed quasi-Sasakian manifold of dimension three admits Ricci soliton, then the Ricci soliton is shrinking.

6. $\tilde{\xi}$-projective curvature tensor on quasi-Sasakian manifold with respect to $D_a$-homothetic deformation

**Definition 6.1.** The $\tilde{\xi}$-projective curvature tensor of type $(1, 3)$ on a quasi-Sasakian manifold of dimension $(2n+1)$ with respect to $D_a$-homothetic deformation is given by [8]

\[ \tilde{P}(X, Y)\tilde{\xi} = \tilde{R}(X, Y)\tilde{\xi} - \frac{1}{2n}[\tilde{S}(Y, \tilde{\xi})X - \tilde{S}(X, \tilde{\xi})Y], \]
The Weyl projective curvature tensor $\bar{P}$ of a three dimensional quasi-Sasakian manifold under $D_a$-homothetic deformation is defined by [8]

$$\bar{P}(X,Y)Z = \bar{R}(X,Y)Z - \frac{1}{2}[\bar{S}(Y,Z)X - \bar{S}(X,Z)Y].$$

(6.1)

Interchanging $X$ and $Y$, we get

$$\bar{P}(Y,X)Z = \bar{R}(Y,X)Z - \frac{1}{2}[\bar{S}(X,Z)Y - \bar{S}(Y,Z)X].$$

(6.2)

Adding (6.1) and (6.2), we get by using the property $\bar{R}(X,Y)Z = -\bar{R}(Y,X)Z$

$$\bar{P}(X,Y)Z + \bar{P}(Y,X)Z = 0.$$

Also, from (6.1) by using first Bianchi identity $\bar{R}(X,Y)Z + \bar{R}(Y,Z)X + \bar{R}(Z,X)Y = 0$, we get

$$\bar{P}(X,Y)Z + \bar{P}(Y,Z)X + \bar{P}(Z,X)Y = 0.$$

Thus the Weyl projective curvature tensor under $D_a$-homothetic deformation in a quasi-Sasakian manifold is skew-symmetric and cyclic.

Using (4.1), (4.4) and (4.6) in (6.1), we get

$$\bar{P}(X,Y)Z = R(X,Y)Z + (1-a)\beta[g(X,Z)\eta(Y)\xi - g(Y,Z)\eta(X)\xi] - g(Y,Z)\eta(X)\xi - 2g(\phi X,Y)\phi Z - g(\phi X,Z)\phi Y$$

$$+ g(\phi Y,Z)\phi X - 2\eta(Y)\eta(Z)X + 2\eta(X)\eta(Z)Y$$

$$- \frac{1}{2}[\eta(X)\eta(Z)Y - \eta(X)\eta(Z)X]$$

$$- \frac{1}{2}[S(Y,Z)X + 2(1-a)\beta\{g(Y,Z)X - 3\eta(Y)\eta(Z)X\}]$$

$$+ 2(1-a)^2\eta(Y)\eta(Z)X - S(X,Z)Y$$

$$- 2(1-a)\beta\{g(X,Z)Y - 3\eta(X)\eta(Z)Y\}$$

$$- 2(1-a)^2\eta(X)\eta(Z)Y].$$

(6.3)

Replacing $Z$ by $\xi$ in (6.3), using (2.4), (2.5) and (4.1), we get

$$\bar{P}(X,Y)\xi = \frac{1}{a}[-(X\beta)\phi Y + (Y\beta)\phi X + \frac{1}{2}(-(\phi X\beta)Y + (\phi Y\beta)X)].$$

Thus we can say

**Theorem 6.1.** The $\xi$-projective curvature tensor on a $D_a$-homothetically deformed quasi-Sasakian manifold of dimension 3 is given by
\[ P(X,Y) \xi = \frac{1}{a}[(-\beta(X)\phi Y + (\beta(Y)\phi X) + \frac{1}{2}(-\phi X\beta Y + (\phi Y\beta)X)], \]

and the manifold is not $\xi$-projectively flat with respect to the $D_\alpha$-homothetic deformation.
