Abstract—Evapotranspiration (ET) is the loss of water to the atmosphere by combined processes of evaporation from soil and plant surfaces and transpiration from plants. Since various factors affect ET, including weather, crops and soil parameters; numerous equations have been developed to quantify standard ET. The equations vary in data requirements from very simple, empirically based or simplified equations to complex, more physically based equations. This study used six methods in estimating standard evapotranspiration using data from September 2011–August 2012 from Climate Station at Masgar (05°10’20” S, 105°10’ 49”E, 50 m dpl) Lampung, Indonesia. The six models are: Hargreaves-Samani 1985 (H/S), FAO 24 Radiation (24RD), FAO 24 Blaney-Criddle (24BC), FAO 24 Pan Evaporation (24PAN), Linacre (Lina), and Makkink (Makk). The results were analyzed using statistics methods in error indicators, which are: Root Mean Square Error(RMSE), Mean Absolute Error (MAE), and Logarithmic Root Mean Square Error(LOG RMSE), while the closeness among the models was analyzed using Index Agreement (IA).

Direct measurement had been done using lysimeters (3x2x1) m. The study concluded that Makkink model is the suitable simple model that should be chosen in Lampung lowland area to calculate ET₀ when climate data is limited, besides the recommended FAO 56 Penman Monteith.

Keyword—Evapotranspiration, Standard Evapotranspiration, FAO 56 PM, Makkink Model.

I. INTRODUCTION

Evaporation is the main component in hydrology cicle, therefore, accurate estimation of evaporation rate is important for water management and eventually for agriculture production. However, it is difficult to measure evaporation rate directly since evaporation affected by various factors.

Evaporation is affected by climate factors such as solar radiation, air temperature and humidity and wind velocity; by crops type and environment and by soil condition and management (Temesken, Davidov and Frame, 2005). Since those factors are linked to each other and change in time and space, it is difficult to develop equation for estimating evaporation rate for various crops on different condition. Therefore, a scheme called reference evapotranspiration was developed.

Reference ET is defined as “the rate of evapotranspiration from an extensive area of 0.08–0.15 m high, uniform, actively growing, green grass that completely shades the soil and is provided with unlimited water and nutrients” (Bakhhtiari et al., 2011). More recently, Allen et al. (1998) elaborated on the concept of ET₀, referring to an ideal 0.12 m high crop with a fixed surface resistance of 70 s m⁻¹ and an albedo of 0.23. Several equations has been developed to estimate the reference evapotranspiration; some of that were derived based on physical processes of the evapotranspiration but mostly are empirical based on statististical relationship between evapotranspiration and one or more climate variables (Berengena and Gavilan, 2005). Approaching methods to estimate evapotranspiration rate was developed increasingly in the last 30 years such as based on air temperature measurement (Hargraeves and Sumani, 1985), based on solar radiation Priestly and Taylor method (Priestly and Taylor, 1972) and based on combination of radiation balance and air moisture aerodynamic movement (Penman, 1948).

Penman method has been improved several times such as Penmann method modified by Monteith and known as Penman-Monteith equation (Monteith, 1965) approach method in FAO 24 version (Doorenbos and Pruitt, 1977), FAO 56 modification (Allen, 1998) and recently Matt-Shuttleworth approaching method (2009). Those estimations have been derived and/or calibrated from the direct field measurement of ET using various grasses of alfalfas on a variety of lysimeter designs, climates, and management conditions.

Some studies showed that Penmann-Monteith model gave accurate estimation that FAO and other organizations
recommended this model to estimate reference evapotranspiration for calculating crops water requirement (Itenfisul et al., 2003; Berengena dan Gavilan, 2005). Even though Penman-Monteith model is accepted as accurate estimation, for using in local condition, it is necessary to validate the model to whether it estimates close enough to the direct measurement on the local climate station. Berengena dan Gavilan (2005) examined different methods in estimating evapotranspiration rate in Southern Spain, an area with strong advection. The result showed that Penman method modified with local wind function gave the best estimation compared with direct measurement in lysimeter following with Penman-Monteith FAO 56 version. Steduto et al. (2003) examine FAO 56 method in Southern Italia with Mediterranean semi-arid climate. The results showed that FAO 56 method was the best in estimating the evapotranspiration; however, tended to be over estimated in winter time when the evapotranspiration was low and underestimated in summer time when the evapotranspiration was high. Temesgen et al. (2005) also examined FAO 56 in California, USA and the result showed good correlations with evapotranspiration rate in 37 climate stations in this area.

Direct measurement of evapotranspiration is calculated using lysimeters; however, only small number of climate stations is equipped with a lysimeter; as an alternative, the measurement is done using evaporation pan known as Class A pan. A study by Fontenot (2004) showed that reference evapotranspiration measurement by Class A pan was not fit to the estimation by Penman-Monteith. The result from Class A pan should be corrected by a coefficient. Using Cuenca and Snyder method; Xing et al. (2008) obtained that pan coefficient for Canada maritint climate was between 0.78 – 0.94. Generally the result from Pan A was lower than the estimation result from Penman-Monteith or Priestley-Taylor method.

Research about comparing different models has been done in some countries. Chen et al. (2005) used 7 estimating models in four provinces of Taiwan and found that Makkink and Hargreaves-Samani models were the best models in estimating ET₀ when compared to FAO 56 PM. Chowhury et al. (2010) also found that in India, Makkink model had the closest estimation to FAO 56 PM with a little underestimated result. Xu and Chen (2005) did similar study in Germany with comparing 7 models and found that Granger-Gray and Makkink models were the best models for the area. In North China, Schneider et al. (2007) compared 4 models with direct observation and concluded that Hargreaves-Samani and Makkink models were the best models in estimating ET₀ even better than FAO 56 PM. Jacobs et al. (2004) conducted research on estimating ET₀ in Florida, using remote sensing method with data from GOES. The results showed that FAO 56 PM is the best model with R²= 0.92; however, this result was not much different with estimated results from Makkink model which gave R²= 0.90.

Various methods in estimating evapotranspiration also has been applied in Indonesia. Usman (2004) compared Thornthwaite, Blaney-Criddle, Samani-Hargreaves, Prestley-Taylor, Jansen-Haise, Penman and Penman-Monteith methods in five climate stations in West Java; the results showed that in general Priestley-Taylor in average gave the highest annual evapotranspiration rate, while the lowest was obtained by Blany-Criddle method. It also showed that estimation using Penman Monteith method in general gave higher rate than Pan A measurement.

Lampung Province (103° 40’ – 105° 50’ E; and between: 6° 45’ – 3° 45’ S;35.288,35 km²) is located at Southeast tip of Sumatra Island, Indonesia. Lampung climate is characterized by monsoon rain distribution and local characteristics. Rain season in general is from October to March with the peak on January/February and dry season is from April to September. Monthly rainfall ranges from 50 – 200 mm and annual rainfall ranges from 1200 mm (lowland area) to 2500 mm (highland area). Lampung economic is dominated by agriculture products mainly coffee, chocolate, rubber and sugarcane. Lampung is also considered as main area for cash crops such as paddy, soybean and Maize. Therefore, finding good and reliable method in estimating crops water requirement is necessary for better agriculture management.

The objective of this research was to find a closest model to the FAO 56 PM model by comparing six different models in estimating standard evapotranspiration in Lampung area, Indonesia.

II. METHODS

This study used six methods in evaluating potential evapotranspiration using data from September 2011 to Agustus 2012 from Climate Station at Masgar (05°10’20” S, 105°10’49”E, 50 m dpl) in Lampung, Indonesia. The six models are: Hargreaves-Samani 1985 (H/S), FAO 24 Radiation (24RD), FAO 24 Blaney-Criddle (24BC), FAO 24 Pan Evaporation (24PAN), Linacre (Lina), dan Makkink (Makk). The results from those models were compared to FAO Penman-Monteith (56PM) as the standard model. To evaluate the relation between models, the results were analyzed using statistics methods in error indicators, which are: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), dan LogaritmicRoot Mean Square
Error (LOG RMSE), while the closeness among the models was analyzed using Index Agreement (IA).

Finally, the results were compared to the direct measurement using 3 lysimeters (3x2x1 m) planted with Sporobolus diander grass.

**2.1 Description of Models**

**2.1.1 Hargreaves-Samani 1985 (H/S) (Hargreaves and Samani, 1985)**

The equation of this model is:

\[ ET_o = 0.0023(T_{mean} + 17.8)(T_{max} - T_{min})^{0.5}R_a \]  \hspace{1cm} (1)

with \( ET_o \) is standard evapotranspiration (mm/day), \( T_{mean} \) is daily mean temperature (°C), \( T_{max} \) is maximum temperature (°C), \( T_{min} \) is minimum temperature, dan \( R_a \) is radiation on top of the atmosphere (MJ/m²/day).

**2.1.2 FAO 24 Radiation (24RD) (Doorenbos and Pruitt, 1977)**

The equation of this model is:

\[ ET_o = a + b \left( \frac{\Delta}{\Delta + \gamma} R_a \right) \]  \hspace{1cm} (2)

\( ET_o \) is standard evapotranspiration (mm/day), \( \Delta \) is vapor pressure curve (kPa/°C), \( \gamma \) is psychrometric constant (kPa/°C), \( R_a \) is solar radiation (MJ/m²/day), and \( a \) and \( b \) are derived from the equation:

\[ b = 1.066 - 0.13 \times 10^{-2} RH_{mean} + 0.045 U_d - 0.20 \times 10^{-3} RH_{mean} U_d \]
\[ -0.1315 \times 10^{-4} RH_{mean}^2 - 0.11 \times 10^{-2} U_d^2 \]  \hspace{1cm} (3)

\( RH_{mean} \) is daily relative humidity (%) and \( U_d \) is average wind velocity at 2 m height (m/s).

**2.1.3 FAO 24 Blaney-Criddle (24BC) (Jensen et al., 1990)**

The equation for this model is:

\[ ET_o = a + b f \]  \hspace{1cm} (4)

\( f = p(0.46T + 8.13) \)  \hspace{1cm} (5)

\[ a = 0.004RH_{min} - \frac{n}{N} - 1.41 \]  \hspace{1cm} (6)

\[ b = 0.908 - 0.00483RH_{min} + 0.7949 \frac{n}{N} \]
\[ + 0.768 \ln(U_d + 1)^2 \]
\[ -0.0038RH_{min} \frac{n}{N} - 0.000443RH_{min} U_d \]
\[ + 0.281 \ln\left( \frac{n}{N} + 1 \right) \]  \hspace{1cm} (7)

\[-0.0097\ln(U_d + 1)[\ln(RH_{min} + 1) + 2 \ln\left( \frac{N}{n} + 1 \right)]\]

\( ET_o \) is standard evapotranspiration (mm/day), \( P \) is percentage of day length, \( T \) is daily average temperature (°C), \( RH \) is minimum relative humidity (%), \( n/N \) is ratio of possible actual day, \( U_d \) is wind speed at 2 m (m/s)

**2.1.4 FAO 24 Pan Evaporation (24PAN) Doorenbos and Pruitt (1977)**

The equation of this model is:

\[ ET_o = K_p \times E_{pan} \]  \hspace{1cm} (8)

\[ K_p = 0.108 - 0.028u_2 + 0.04221\ln(FET) \]
\[ + 0.1434 \ln(RH_{mean}) \]
\[-0.000631(\ln(FET))^2 \ln(RH_{mean}) \]  \hspace{1cm} (9)

\( ET_o \) is standard evapotranspiration (mm/day), \( K_p \) is pan coefficient, \( E_{pan} \) is class A Pan evaporation (mm/day), \( u_2 \) is average wind speed (m/s), \( RH_{mean} \) is relative humidity (%), dan \( FET \) is distance between pan and green crops (m).

**2.1.5 Linares (LINAC) (Linares, 1977)**

The equation of this model is:

\[ ET_o = \frac{\left( \frac{500T_m}{100 - A} \right) + 15(T - T_d)}{(80 - T)} \]  \hspace{1cm} (10)

\[ T_m = T + 0.006h \]  \hspace{1cm} (11)

\( ET_o \) is standard evapotranspiration (mm/day), \( T \) is mean temperature (°C), \( A \) is latitude of the climate station (°), \( T_m \) is elevation of climate station (m), dan \( T_d \) is average dew point temperature (°C). \( T_d \) equation is:

\[ T_d = \left( \frac{1}{100} \right)^{\frac{1}{2}} (112 + 0.9T) + 0.17 - 112 \]  \hspace{1cm} (12)

is average dew point temperature (°C), \( T \) is mean temperature (°C), dan \( f \) is average daily relative humidity (%).

**2.1.6 Makkink (Makk) (Makkink, 1957).**

The equation of this model is:

\[ ET_o = 0.61 \times \frac{\Delta}{\Delta + \gamma} R_s - 0.12 \]  \hspace{1cm} (13)

\( ET_o \) is average dew point temperature (°C). \( R_s \) is solar radiation (MJ/m²/day), \( \Delta \) is vapor pressure curve (kPa/°C), and \( \gamma \) is psychrometric constant (kPa/°C).
2.1.7 FAO 56 PM (56PM) (Allen et al., 1998)

The equation of this model is

\[ ET_o = 0.408\Delta (R_n - G) + \gamma \frac{900}{T+273} U_2 (e_s - e_a) \]  
\[ \Delta = \gamma (1 + 0.34 U_2) \]  

\( ET_o \) is standard evapotranspiration (mm/day), \( R_n \) is netto radiation on crops surface (MJ/m²/day), \( G \) is continuous heat flux to soil depth (MJ/m²/day), \( T \) is daily temperature at 2 m (°C), \( U_2 \) is wind speed at 2 m (m/s), \( e_s \) is actual vapor pressure (kPa), \( e_a \) is psychrometric constant (kPa°C).

In this study the \( ET_o \) estimation from FAO 56 Penman-Monteith model as the standard model was calculated using CROPWAT. CROPWAT is a computer program recommended by FAO based on FAO 56 Penman-Monteith model (Allen et al., 1998)

2.1.8 Indicators

The error indicators equation used to evaluate the model follows Wilmorth (1982):

\[ RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (ET_{osi} - ET_{omi})^2} \]  

\[ MAE = \frac{1}{N} \sum_{i=1}^{N} |ET_{osi} - ET_{omi}| \]  

\[ LOG = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (\log ET_{osi} - \log ET_{omi})^2} \]  

\[ I.A = 1 - \frac{\sum (ET_{osi} - ET_{omi})^2}{\sum ||ET_{osi}'||^2 + \sum ||ET_{omi}'||^2} \]  

\[ ET_{osi}' = ET_{osi} - ET_{omi} \]  

\[ ET_{omi}' = ET_{omi} - ET_{omi} \]  

With \( ET_{osi} \) is Penman-Monteith standard evapotranspiration as the standard model and \( ET_{omi} \) is others evapotranspirasi models (i).

Table 1: Climate parameters needed by each estimation model

| No | Model | Climate data needed by each model |
|----|-------|----------------------------------|
| 1  | 56PM  | ✓                               |
| 2  | H/S   | ✓                               |
| 3  | 24RD  | ✓                               |
| 4  | 24 BC | ✓                               |
| 5  | 24PAN | ✓                               |
| 6  | Makk  | ✓                               |
| 7  | LINA  | ✓                               |

Notes: \( E_{pan} \) : Evaporation pan (mm/day); \( T \) : average, maximum and minimum temperature (°C); \( R_s \) : solar radiation (MJ/m²/day); \( R_r \) : netto radiation (MJ/m²/day); \( RH \) : relative humidity (%); \( P \) : day length (%); \( U_2 \) : wind velocity (m/s); \( R_2 \) : radiation at the top of the atmosphere (MJ/m²/day)

III. RESULTS AND DISCUSSIONS

3.1. Statistical analysis

The statistical analysis from daily evapotranspiration data including the error indicator of each model compare to the FAO 56 PM as the standard is presented in Table 2-5.

Table 2: RMSE value among the \( ET_o \) estimating models

| RMSE | 56PM | Makk | 24BC | 24PAN | 24RD | H/S | Lina |
|------|------|------|------|-------|------|-----|------|
| 56PM | 0.34 | 0.75 | 0.69 | 1.35  | 0.88 | 0.88|      |
Comparison of error indicator (RMSE) between models using monthly data was presented in Table 2. Based on the comparison among the six models, the error indicator RMSE ranged from 0.33-1.99 which means that ET₀ difference among the models was 0.32 mm to 1.99 mm/day. This is not a small number since 1 mm/day ET in 1 ha area is equivalent with water loss of 10,000 liter/day or 3.6 million liter/year. Using Lampung climate data, the lowest RMSE was found between FAO 24 Radiation and FAO 24 Pan Evaporation while the highest RMSE was found between model FAO 24 Pan Evaporation and FAO 24 Blaney-Criddle.

Table 3: MAE value of estimated monthly evapo-transpiration data among the models

| Model | MAE 56PM | Makk | 24BC | 24PA | 24RD | H/S | Lina |
|-------|---------|------|------|------|------|-----|------|
| 56PM  | 0.28    | 1.06 | 0.62 | 0.67 | 1.28 | 0.8 | 6    |
| Makk  | 0.28    | 1.28 | 0.40 | 0.45 | 1.50 | 1.0 | 8    |
| 24BC  | 1.06    | 1.28 | 0.69 | 1.74 | 0.95 | 0.6 | 8    |
| 24PA  | 0.62    | 0.40 | 1.69 | 0.25 | 1.90 | 1.4 | 8    |

The second error indicator (MAE) is presented in Table 3. Similar results with RMSE were found in error indicators for both MAE and log RMSE (Table 4). Makkink model was the model which is closest to FAO 56 Pennman Monteith.

Table 4: LOG RMSE among the estimating models of ET₀

| LOG RMSE | 56PM | Makk | 24BC | 24PAN | 24RD |
|----------|------|------|------|-------|------|
| 56PM     | 0.04 | 0.13 | 0.11 | 0.10  | 0.10 |
| Makk     | 0.17 | 0.08 | 0.33 | 0.06  | 0.07 |
| 24BC     | 0.23 | 0.23 | 0.23 | 0.23  | 0.22 |
| 24PAN    | 0.07 | 0.06 | 0.22 | 0.22  | 0.22 |
| H/S      | 0.11 | 0.16 | 0.11 | 0.11  | 0.11 |
| Lina     | 0.08 | 0.08 | 0.20 | 0.20  | 0.19 |

MAE between FAO 56 Penman-Monteith and other models ranges from 0.28 mm/day (Makkink) up to 1.28 mm/day (Hargreaves-Samani 1985) and LOG RMSE ranges from 0.04 mm/day (Makkink) to 0.14 mm/day (Hargreaves-Samani).

Table 5 showed the results of Index of Agreement (IA). Consistently, Makkink model gave the best results with IA 0.78 followed by Linarch (0.42) and FAO Pan Evaporation (0.42).

Table 5: Index of Agreement among the models

| Model  | PM  | MK  | BC  | Pan | 24RD | HS  | Ln  |
|--------|-----|-----|-----|-----|------|-----|-----|
| PM     | 1   | 0.78| 0.09| 0.42| 0.55 | 0.26| 0.42|
| MK     | 0.78| 1   | -0.35| 0.80| 0.81 | 0.10| 0.10|
| BC     | 0.09| -0.35| 1   | -0.40| -0.22| 0.79| 0.85|
| Pan    | 0.42| 0.80| -0.40| 1   | 0.95 | -0.03| -0.08|
| 24RD   | 0.55| 0.81| -0.22| 0.95| 1   | -0.03| -0.01|
| HS     | 0.26| 0.10| 0.79| -0.03| -0.03| 1   | 0.93|
| Ln     | 0.42| 0.10| 0.85| -0.08| -0.01| 0.93| 1   |

The resume of statistical analysis from daily evapo transpiration data including the error indicator of each model compare to the FAO 56 PM as the standard was presented in Table 6.
Table 6: Statistical of daily evapotranspiration data from each model

| Evapotranspiration Model | Average | STD | RMSE  | MAE  | LOG RMSE | LA   |
|-------------------------|---------|-----|-------|------|----------|------|
|                        | 24      | BC  | HS    | Mk   | Lin      | Pan  | FAO  |
| Average                | 2,851   | 4,607 | 4,821 | 3,306 | 4,387     | 2,925 | 3,533 |
| STD                    | 0.485   | 1,419 | 0.561 | 0.370 | 0.569     | 1,009 | 0.774 |
| RMSE                   | 0.884   | 1,392 | 1,481 | 0.683 | 1,065     | 1,283 |
| MAE                    | 0.749   | 1,107 | 1,294 | 0.571 | 0.890     | 1,037 |
| LOG RMSE               | 0.117   | 0.130 | 0.170 | 0.088 | 0.131     | 0.239 |
| LA                     | 0.439   | 0.565 | -0.403 | 0.595 | 0.263     | 0.363 |

Table 6 showed that among the models, Makink model consistently had the smallest RMSE, MAE and Log RMSE compared to PM model and had the highest agreement. On the other hand HS model had the biggest RMSE, MAE and log RMSE with the lowest agreement. Therefore, for Lampung, estimation ET model with the closest estimation to FAO 56 Penman-Monteith was Makink model. It can be concluded that Makink model was the suitable simple model that should be chosen in Lampung to calculate ET₀ besides the recommended one, FAO 56 Penman Monteith, especially when the climate data is limited.

So far the estimating model that broadly used is FAO 24 PAN which is based on observation on Pan A evaporation pan. In this study this model did not give a good estimation compared to the FAO 56 PM model (RMSE 0.75; MAE 0.62; Log RMSE 0.11 and IA 0.42). In comparing 24 PAN model to 56 PM, using 3 years data in 2 stations in Lampung, Manik et al. (2012) found that the coefficient correlation between those two models are low (r=0.3 for Branti Station and 0.5 for Masgar station).

Daily modeled ET₀ results from each model in 1 year is presented in Figure 2. Most of the models had similar trends with FAO 56 PM but with different estimation. Some models underestimated FAO 56 PM (Makink, FAO 24 Radiation and FAO 24 Pan Evaporation) while some overestimated (Blaney Criddle, Hargreaves-Samani 1985 and Linarch). Makink model had good estimation to FAO 56 PM in wet months October-March, and slightly underestimated in dry months March – October.

In general, Makink model is a function of Rₛ (solar radiation MJ/m²/day), Δ(slope of vapour pressure), and γ(psychrometric constant). Makink is a simple model since γ is 66.1 (kPa/°C), while Rₛ and Δ could be calculated using following equations (Allen, et al., 1998):

\[ Rₛ = Kᵣₑₑ \sqrt{(T_max - T_min)R_a} \ldots (21) \]

\[ \Delta = \frac{4098 [0.6108 \exp \left(\frac{17.277}{T + 237.3}\right)]}{(T + 237.3)^{2}} \ldots (22) \]

Kᵣₑₑ is a coefficient, 0.16 for interior land area and 0.19 for coastal area, R_a is top solar radiation (MJ/m²/day). Basically, this model can be calculated using only maximum and minimum temperature (°C) which is more available in most research stations.

Irmak, Allen and Whitty (2003) conducted a research using daily measured weather data for a 23-year (1978–2000) in North-Central Florida to examine twenty one ET₀ methods (excluding the FAO 56-PM; 10 combination methods, 4 radiation methods, 5 temperature methods and 2 pan evaporation methods) and the results showed that the performance of all radiation methods including Makink was poorer than that of all combination methods except the Stephens-Stewart method, which performed better than the original PM combination method. Makink methods had a similar standard error of estimate for all months with the Stephens-Stewart method, but the method significantly underestimated ET₀ throughout the year.

The tendency to underestimate high evaporative demand in Makink model has been found in most of previous studies e.g. in Korea (Chen, et al., 2005), in Germany (Xu and Chen, 2005) in Jordan (Mohawesh, 2011) in Iran (Bakhtiar et al., 2011); those results might be related to the ignorance of the significant influence of wind speed on ET₀. Regardless of that, Makink model was considered as a good option model and the closest to Penman Monteith method in India (Haldar, Kumar and Sehgal, 2005) and in Hungary (Racz, et al., 2013).
3.2. Comparing Makkink model with direct measurement

Direct evapotranspiration measurement was done using lysimeters. Measuring water input and out put together with soil water content on the lysimeters was a challenge. During this research the measurements were repeated several times, however due to technical problems they were not always done in the same day. Therefore, the results (Table 7 and 8) were considered as an average number.

In average from Table 7 and 8, evapotranspiration rate during the research was 3.8 ±1.11 = 4.91 mm/day, higher than estimated Makkink (3.306 mm) and FAO (3.533 mm) (Table 6). In general, the average and accumulation of observed Pan A gave slightly higher evapotranspiration compared to estimated Makkink. However, observed Pan A had much wider standard deviation; Makkink model gave more flat result in daily estimation while Pan A was more fluctuates.

Table 7: Water input and output to the lysimeters

| Time of Observation (n) | Rainfall (R) (mm) | Irrigation (I) (mm) | Percolation (P) (mm) | R+I-P (mm) |

IV. CONCLUSION
This study concluded that Makkink model is a simple model that can be chosen in Lampung as an alternative to estimate standard evapotranspiration in an area with limited climate data needed to apply FAO 56 PM, with a note that Makkink tended to be underestimated during dry months. Estimation of evapotranspiration using models are sufficient for averaged and accumulated result from some period of time, not for daily or single measurement.
