Abstract
A scale–dependent effective action for gravity is introduced and an exact nonperturbative evolution equation is derived which governs its renormalization group flow. It is invariant under general coordinate transformations and satisfies modified BRS Ward–Identities. The evolution equation is solved for a simple truncation of the space of actions. In $2+\varepsilon$ dimensions, nonperturbative corrections to the $\beta$–function of Newton’s constant are derived and its dependence on the cosmological constant is investigated. In 4 dimensions, Einstein gravity is found to be “antiscreening”, i.e., Newton’s constant increases at large distances.
1 Introduction

In many of the traditional approaches to quantum gravity the Einstein–Hilbert term has been regarded as a fundamental action which should be quantized along the same lines as the familiar renormalizable field theories in flat space, such as QED for example [1]. It was soon realized that this program is not only technically rather involved but also leads to severe conceptual difficulties. In particular, the nonrenormalizability of the theory hampers a meaningful perturbative analysis. While this does not rule out the possibility that the theory exists nonperturbatively, not much is known in this direction. However, it could also be argued that gravity, as we know it, should not be quantized at all, because Einstein gravity is an effective theory [2] which results from quantizing some yet unknown fundamental theory. If so, the Einstein–Hilbert term is an effective action analogous to the Heisenberg–Euler action in QED and it should not be compared to the “microscopic” action of electrodynamics.

It seems not unreasonable to assume that the truth lies somewhere between those two extreme points of view, i.e., that Einstein gravity is an effective theory which is valid near a certain nonzero momentum scale $k$. This means that it arises from the fundamental theory by a “partial quantization” in which only excitations with momenta larger than $k$ are integrated out, while those with momenta smaller than $k$ are not included. (The interpretation of the Einstein–Hilbert term as a fundamental or an ordinary effective action is recovered in the limits $k \to \infty$ and $k \to 0$, respectively.) An “effective theory at scale $k$”, when evaluated at tree level, should correctly describe all gravitational phenomena which involve a typical momentum scale $k$ acting as a physical infrared cutoff. Only if one is interested in processes with momenta $k' \ll k$, loop calculations become necessary; they amount to integrating out the missing field modes in the momentum interval $[k', k]$.

We shall regard the scale-dependent action for gravity, henceforth denoted $\Gamma_k$, as a Wilsonian effective action which is obtained from the fundamental (“microscopic”) action $S$ by a kind of coarse-graining analogous to the iterated block-spin transformations which are familiar from lattice systems [3]. In the continuum, $\Gamma_k$ will be defined in terms of a modified functional integral over $e^{-S}$ in which the contributions of all field modes with momenta smaller than $k$ are suppressed. In
this manner $\Gamma_k$ interpolates between $S$ (for $k \to \infty$) and the effective action $\Gamma$ (for $k \to 0$). The trajectory in the space of all action functionals can be obtained as the solution of a certain functional evolution equation, the exact renormalization group equation. Its form is independent of the action $S$ under consideration. The latter enters via the initial conditions for the renormalization group trajectory; it is specified at some UV cutoff scale $\Lambda$: $\Gamma_\Lambda = S$. If $S$ is a truly fundamental action, $\Lambda$ is sent to infinity at the end. The renormalization group equation can also be used to evolve effective actions, known at some point $\Lambda$, towards smaller scales $k < \Lambda$. In this case $\Lambda$ is a fixed, finite scale. In this framework, the (non)renormalizability of a theory is seen as a global property of the renormalization group flow for $\Lambda \to \infty$. The evolution equation by itself is perfectly finite and well behaved in either case, because it describes only infinitesimal changes of the cutoff.

In this paper we shall give a precise meaning to the notion of a scale–dependent gravitational action $\Gamma_k[g_{\mu\nu}]$ and we shall derive the associated evolution equation. We employ a formulation in which the metric is the fundamental dynamical variable. Alternative approaches based upon the spin–connection and the vielbeins are also possible, but they will not be considered here. By using a variant of the background gauge technique we are able to make $\Gamma_k[g_{\mu\nu}]$ invariant under general coordinate transformations. This property is very important if one wants to find nonperturbative solutions of the evolution equations in terms of simple truncations of the space of actions. Our construction of $\Gamma_k[g_{\mu\nu}]$ parallels the definition of the “effective average action” \[4, 5\] which was widely used recently \[1, 2, 3, 4\]. The remarkable successes of this method in flat space are partly due to the fact that it allows for nonperturbative solutions when no small expansion parameter is available, and that $\Gamma_k$ has a built–in infrared cutoff. Therefore the low–momentum behavior of (almost) massless theories can be investigated even in cases where IR divergences render standard perturbation theory inapplicable. For the purposes of quantum gravity, both of these features are very welcome, of course. In fact, in quantum cosmology one of the most intriguing questions is how quantized Einstein gravity behaves at extremely large distances. It has been argued \[13, 14\] that in presence of a nonzero cosmological constant there should

\[1\] For related work using similar techniques see refs. \[10, 11, 12\].
be very strong renormalization effects in the infrared which might even provide a mechanism for a dynamical relaxation of the cosmological constant. The method which we are going to develop would be ideally suited to study problems of this type. Since only long distance physics is involved here, there are good chances that this can be done without knowing the microscopic theory of quantum gravity. (See ref. [2] for a related discussion.)

The “effective average action” used in this paper should not be confused with the closely related “average action” which was introduced earlier [15]. The former obeys a more convenient evolution equation while the latter has a simple interpretation in terms of field averages. Their precise relation is explained in ref. [16]. The average action has been used in a gravitational context in refs. [17], [18], but no exact evolution equation was formulated. The evolution of the effective average action in a gravitational background was studied in ref. [19] in the context of Liouville field theory. For a review of the effective average action and its application to Yang–Mills theory we refer to [20].

The remaining sections of this paper are organized as follows. In section 2 we give the definition of \( \Gamma_k \) and derive the exact, nonperturbative renormalization group equation. In section 3 we establish the modified Ward identities satisfied by \( \Gamma_k \), and we show that the conventional diffeomorphism Ward identities are recovered in the limit \( k \to 0 \). In its general form, the evolution equation describes a flow on the infinite dimensional space of all action functionals. Approximate nonperturbative solutions can be found by truncating the space of actions, i.e., by projecting the flow on a finite–dimensional subspace. In section 4 we investigate the “Einstein–Hilbert truncation” where only the operators \( \int \sqrt{g} \) and \( \int \sqrt{g}R \) are retained. In section 5 we determine the resulting scale dependence of Newton’s constant and of the cosmological constant. As an example, gravity in \( d + \varepsilon \) and in 4 dimensions is discussed in detail.

## 2 The Renormalization Group Equation

In this section we introduce the effective average action for euclidean quantum gravity in \( d \) dimensions and we derive the exact renormalization group equation which governs its scale dependence.

We are going to employ the background gauge fixing technique [21], [22] which
means that we decompose the integration variable $\gamma_{\mu\nu}(x)$ in the functional integral over all metrics according to

$$\gamma_{\mu\nu}(x) = \bar{g}_{\mu\nu}(x) + h_{\mu\nu}(x) \quad (2.1)$$

Here $\bar{g}_{\mu\nu}$ is a fixed background metric so that the integration over $\gamma_{\mu\nu}$ may be replaced by an integration over $h_{\mu\nu}$. We consider the following scale-dependent modification of the generating functional for the connected Green’s functions

$$\exp \{ W_k [t^{\mu\nu}, \sigma^\mu, \bar{\sigma}^\mu; \beta^{\mu\nu}, \tau_\mu; \bar{g}_{\mu\nu}] \} = \int \mathcal{D}h_{\mu\nu} \mathcal{D}C^\mu \mathcal{D}\bar{C}_\mu \exp \left\{ -S[\bar{g} + h] - S_{gf}[h; \bar{g}] - S_{gh}[h, C, \bar{C}; \bar{g}] - S_{source} \right\} \quad (2.2)$$

Here $S[\gamma] = S[\bar{g} + h]$ is the classical action which is assumed to be invariant under the general coordinate transformations

$$\delta \gamma_{\mu\nu} = \mathcal{L}_v \gamma_{\mu\nu} \equiv v^\rho \partial_\rho \gamma_{\mu\nu} + \partial_\mu v^\rho \gamma_{\rho\nu} + \partial_\nu v^\rho \gamma_{\mu\rho} \quad (2.3)$$

where $\mathcal{L}_v$ denotes the Lie derivative with respect to the vector field $v^\mu$. For the time being let us also assume that $S$ is positive definite.

Furthermore, $S_{gf}$ denotes the gauge fixing term for the gauge condition $F_\mu(\bar{g}, h) = 0$,

$$S_{gf}[h; \bar{g}] = \frac{1}{2\alpha} \int d^d x \sqrt{\bar{g}} \bar{g}^{\mu\nu} F_\mu F_\nu \quad (2.4)$$

and $S_{gh}$ is the action for the corresponding Faddeev–Popov ghosts $C^\mu$ and $\bar{C}_\mu$:

$$S_{gh}[h, C, \bar{C}; \bar{g}] = -\kappa^{-1} \int d^d x \bar{C}_\mu \bar{g}^{\mu\nu} \frac{\partial F_\nu}{\partial h_{\alpha\beta}} \mathcal{L}_C (\bar{g}_{\alpha\beta} + h_{\alpha\beta}) \quad (2.5)$$

The Faddeev–Popov action $S_{gh}$ is obtained along the same lines as in Yang–Mills theory: one applies a gauge transformation

$$\delta h_{\mu\nu} = \mathcal{L}_v \gamma_{\mu\nu} = \mathcal{L}_v (\bar{g}_{\mu\nu} + h_{\mu\nu}) \quad \delta \bar{g}_{\mu\nu} = 0 \quad (2.6)$$

to $F_\mu$ and replaces the parameters $v^\mu$ by the ghost field $C^\mu$. The integral over $C^\mu$ and $\bar{C}_\mu$ provides a representation of the Faddeev–Popov determinant $\det[\delta F_\mu/\delta v^\nu]$.
then. In eq. \((2.3)\) we introduced the constant (proportional to the Planck mass)

\[
\kappa \equiv \left(32\pi G\right)^{1/2}
\]  

(2.7)

where \(\bar{G}\) denotes the bare Newtonian constant. In principle our construction works for an arbitrary background gauge fixing. It is particularly convenient to use a \(F_{\mu}\) which is linear in the quantum field \(h_{\mu\nu}\):

\[
F_{\mu} = \sqrt{2\kappa} F_{\mu}^{\alpha\beta}[\bar{g}] h_{\alpha\beta}
\]  

(2.8)

We shall mostly employ the harmonic coordinate condition for which \(F_{\mu}^{\alpha\beta}\) is the following first order differential operator constructed from \(\bar{g}_{\mu\nu}\):

\[
F_{\mu}^{\alpha\beta} = \delta_{\mu}^{\beta} \bar{g}^{\sigma\gamma} \bar{D}_\gamma - \frac{1}{2} \bar{g}^{\alpha\beta} \bar{D}_\mu
\]  

(2.9)

The covariant derivative \(\bar{D}_\mu\) involves the Christoffel symbols \(\bar{\Gamma}_{\mu\nu}^\rho\) of the background metric \(\bar{g}_{\mu\nu}\). For the gauge fixing \((2.8)\) with \((2.9)\) the ghost action reads

\[
S_{gh}[h,C,\bar{C};\bar{g}] = -\sqrt{2} \int d^d x \sqrt{\bar{g}} \bar{C}_\mu \mathcal{M}[g,\bar{g}]^\mu_\nu C^\nu
\]  

(2.10)

with the Faddeev–Popov operator

\[
\mathcal{M}[g,\bar{g}]^\mu_\nu = \bar{g}^{\mu\rho} \bar{g}^{\sigma\lambda} \bar{D}_\sigma (g_{\rho\nu} D_\lambda + g_{\sigma\nu} D_\rho) - \bar{g}^{\rho\sigma} \bar{g}^{\mu\lambda} \bar{D}_\lambda g_{\sigma\nu} D_\rho
\]  

(2.11)

The essential piece in eq.\((2.2)\) is the IR cutoff for the gravitational field \(h_{\mu\nu}\) and for the ghosts:

\[
\Delta_k S[h,C,\bar{C};\bar{g}] = \frac{1}{2} \kappa^2 \int d^d x \sqrt{\bar{g}} \bar{C}_\mu R_{k}^{grav}[\bar{g}]^\mu_\nu R_{k}^{grav}[\bar{g}]^\nu_\rho h^\rho_\sigma
\]  

(2.12)

\[+ \sqrt{2} \int d^d x \sqrt{\bar{g}} \bar{C}_\mu R_{k}^{gh}[\bar{g}] C^\mu \]

The cutoff operators \(R_{k}^{grav}\) and \(R_{k}^{gh}\) serve the purpose of discriminating between high–momentum and low–momentum modes. Eigenmodes of \(-\bar{D}^2\) with eigenvalues \(p^2 \gg k^2\) are integrated out in \((2.2)\) without any suppression whereas modes with small eigenvalues \(p^2 \ll k^2\) are suppressed by a kind of momentum dependent mass term. The operators \(R_{k}^{grav}\) and \(R_{k}^{gh}\) describe the transition from the high–momentum to the low–momentum regime. Either of them has the structure

\[
R_{k}[\bar{g}] = \mathcal{Z}_k k^2 R^{(0)}(-\bar{D}^2/k^2)
\]  

(2.13)
where the dimensionless function $R(0)$ interpolates smoothly between $R^{(0)}(0) = 1$ and $\lim_{u \to \infty} R^{(0)}(u) = 0$. A convenient choice is for example

$$R^{(0)}(u) = u[\exp(u) - 1]^{-1} \quad (2.14)$$

The factors $Z_k$ are different for the graviton and the ghost cutoff. For the ghost $Z_k \equiv Z_k^{gh}$ is a pure number, whereas for the metric fluctuation $Z_k \equiv Z_k^{grav}$ is a tensor constructed from the background metric $\bar{g}_{\mu\nu}$. In the simplest case one would take

$$(Z_k^{grav})_{\mu\nu\rho\sigma} = \bar{g}_{\mu\rho} \bar{g}_{\nu\sigma} Z_k^{grav} \quad (2.15)$$

In section 4 we shall employ a slightly more refined choice. There we shall also explain how the factors $Z_k^{gh}$ and $Z_k^{grav}$ should be choosen. Note that the cutoff action (2.12) is quadratic in the quantum fields $h_{\mu\nu}$, $C^\mu$ and $\bar{C}_\mu$. This is an important prerequisite for obtaining a tractable evolution equation later on. The requirement of a quadratic $\Delta_k S$ forces us to use the covariant Laplacian $\bar{D}^2 \equiv \bar{g}^{\mu\nu} \bar{D}_\mu \bar{D}_\nu$ in the background metric as the operator which discriminates between high–momentum and low–momentum modes.

In (2.2) we coupled $h_{\mu\nu}$, $C^\mu$ and $\bar{C}_\mu$ to the sources $t^{\mu\nu}$, $\bar{\sigma}_\mu$ and $\sigma^\mu$, respectively:

$$S_{\text{source}} = - \int d^dx \sqrt{\bar{g}} \left\{ t^{\mu\nu} h_{\mu\nu} + \bar{\sigma}_\mu C^\mu + \sigma^\mu \bar{C}_\mu + \beta^{\mu\nu} \mathcal{L}_C (\bar{g}_{\mu\nu} + h_{\mu\nu}) + \tau_\mu C^\nu \partial_\nu C^\mu \right\} \quad (2.16)$$

The sources $\beta^{\mu\nu}$ and $\tau_\mu$ couple to the BRS variations of $h_{\mu\nu}$ and $C^\mu$, respectively. In fact, it is not difficult verify that $S + S_{gf} + S_{gh}$ is invariant under the BRS transformations ($\varepsilon$ is an anticommuting parameter)

$$\delta_\varepsilon h_{\mu\nu} = \varepsilon \kappa^{-2} \mathcal{L}_C \gamma_{\mu\nu} = \varepsilon \kappa^{-2} \mathcal{L}_C (\bar{g}_{\mu\nu} + h_{\mu\nu})$$

$$\delta_\varepsilon \bar{g}_{\mu\nu} = 0$$

$$\delta_\varepsilon C^\mu = \varepsilon \kappa^{-2} C^\nu \partial_\nu C^\mu$$

$$\delta_\varepsilon \bar{C}_\mu = \varepsilon (\alpha \kappa)^{-1} F_\mu \quad (2.17)$$

Given the functional $W_k$, we introduce $k$–dependent classical fields

$$\bar{h}_{\mu\nu} = \frac{1}{\sqrt{g}} \frac{\delta W_k}{\delta t^{\mu\nu}} \quad ; \quad \xi^\mu = \frac{1}{\sqrt{g}} \frac{\delta W_k}{\delta \bar{\sigma}_\mu} \quad ; \quad \bar{\xi}_\mu = \frac{1}{\sqrt{g}} \frac{\delta W_k}{\delta \sigma^\mu} \quad (2.18)$$
and we formally solve for the sources \((t^{\mu\nu}, \sigma^{\mu}, \bar{\sigma}^{\mu})\) as functionals of the fields \((\bar{h}^{\mu\nu}, \xi^{\mu}, \bar{\xi}^{\mu})\) and of \((\beta^{\mu\nu}, \tau^{\mu}; \bar{g}_{\mu\nu})\). Then the Legendre transform \(\tilde{\Gamma}_k\) of \(W_k\) depends on the classical fields and parametrically on \(\beta, \tau\) and \(\bar{g}\):

\[
\tilde{\Gamma}_k[\bar{h}, \xi; \bar{\xi}; \beta, \tau; \bar{g}] = \int d^dx \sqrt{\bar{g}} \left\{ t^{\mu\nu} \bar{h}_{\mu\nu} + \bar{\sigma}^{\mu} \xi^{\mu} + \sigma^{\mu} \bar{\xi}^{\mu} \right\} - W_k[t, \sigma, \bar{\sigma}; \beta, \tau; \bar{g}] \quad (2.19)
\]

By definition, the effective average action \(\Gamma_k\) obtains from \(\tilde{\Gamma}_k\) by subtracting the cutoff action \(\Delta_k S\) with the classical fields inserted:

\[
\Gamma_k[\bar{h}, \xi, \bar{\xi}; \beta, \tau; \bar{g}] = \tilde{\Gamma}_k[\bar{h}, \xi, \bar{\xi}; \beta, \tau; \bar{g}] - \Delta_k S[\bar{h}, \xi, \bar{\xi}; \bar{g}] \quad (2.20)
\]

It is convenient to define the metric

\[
g_{\mu\nu}(x) \equiv \bar{g}_{\mu\nu}(x) + \bar{h}_{\mu\nu}(x) \quad (2.21)
\]

as the classical analogue of the quantum metric \(\gamma_{\mu\nu} \equiv \bar{g}_{\mu\nu} + h_{\mu\nu}\) and to consider \(\Gamma_k\) as a functional of \(g_{\mu\nu}\) rather than \(\bar{h}_{\mu\nu}\):

\[
\Gamma_k[g_{\mu\nu}, \bar{g}_{\mu\nu}, \xi^{\mu}, \bar{\xi}^{\mu}; \beta, \tau] \equiv \Gamma_k[g_{\mu\nu} - \bar{g}_{\mu\nu}, \xi^{\mu}, \bar{\xi}^{\mu}; \beta, \tau; \bar{g}_{\mu\nu}] \quad (2.22)
\]

The main virtue of the background technique employed here is that the functional \(\Gamma_k\) is invariant under general coordinate transformations where all its arguments transform as tensors of the corresponding rank:

\[
\Gamma_k[\Phi + L_v \Phi] = \Gamma_k[\Phi], \quad \Phi \equiv \left\{ g_{\mu\nu}, \bar{g}_{\mu\nu}, \xi^{\mu}, \bar{\xi}^{\mu}; \beta^{\mu\nu}, \tau^{\mu} \right\} \quad (2.23)
\]

Note that in (2.23), contrary to the “gauge transformation” (2.6), also the background metric transforms as an ordinary tensor field: \(\delta \bar{g}_{\mu\nu} = L_v \bar{g}_{\mu\nu}\). Eq. (2.23) is a consequence of

\[
W_k[J + L_v J] = W_k[J], \quad J \equiv \left\{ t^{\mu\nu}, \sigma^{\mu}, \bar{\sigma}^{\mu}; \beta^{\mu\nu}, \tau^{\mu}; \bar{g}_{\mu\nu} \right\} \quad (2.24)
\]

This invariance property follows from (2.2) if one performs a compensating transformation on the integration variables \(h_{\mu\nu}, \bar{C}^\mu\), and \(\bar{C}^\mu\). At this point we assume that the measure is diffeomorphism invariant.

The general coordinate invariance of \(\Gamma_k\) is of major practical importance because if we know a priori that no symmetry-violating terms are generated during the evolution it is sufficient to use truncations which consist of invariant combinations of the fields only. The conventionally defined effective action of the metric,
\( \Gamma[g_{\mu\nu}] \), obtains in the limit of a vanishing IR cutoff by setting the ghosts, \( \beta \) and \( \tau \) to zero and by identifying \( \bar{g}_{\mu\nu} \) with \( g_{\mu\nu} \):

\[
\Gamma[g_{\mu\nu}] = \lim_{k \to 0} \Gamma_k[g_{\mu\nu}, g_{\mu\nu}, 0, 0, 0, 0] \quad (2.25)
\]

As a consequence, \( \Gamma[g_{\mu\nu}] \) is invariant under \( \delta g_{\mu\nu} = \mathcal{L}_v g_{\mu\nu} \). Even though we are mostly interested in the functional

\[
\bar{\Gamma}_k[g_{\mu\nu}] \equiv \Gamma_k[g_{\mu\nu}, g_{\mu\nu}, 0, 0, 0, 0] \quad (2.26)
\]

which depends on \( g_{\mu\nu} \) only, an exact renormalization group equation can be formulated only if one keeps track of the dependence on \( \xi, \bar{\xi} \) and \( \bar{g} \) as well. For the derivation of the (modified) BRS Ward identities satisfied by \( \bar{\Gamma}_k \) the dependence on \( \beta \) and \( \tau \) must be retained in addition.

The derivation of the evolution equation for \( \bar{\Gamma}_k \) proceeds as follows. Taking a derivative of the functional integral (2.2) with respect to the renormalization group “time” \( t \equiv \ln k \) one obtains, in matrix notation

\[
- \partial_t W_k = \frac{1}{2} \text{Tr} \left[ < h \otimes h > \left( \partial_t \hat{R}_k \right)_{hh} \right] - \text{Tr} \left[ < \bar{C} \otimes C > \left( \partial_t \hat{R}_k \right)_{\xi\xi} \right] \quad (2.27)
\]

Here \( \hat{R}_k \) is a matrix in field space whose non-zero entries are

\[
\left( \hat{R}_k \right)_{hh}^{\mu\nu\rho\sigma} = \kappa^2 \left( R_k^{\text{grav}} [\bar{g}] \right)^{\mu\nu\rho\sigma}
\]

\[
\left( \hat{R}_k \right)_{\xi\xi} = \sqrt{2} R_k^{\text{gh}} [\bar{g}] \quad (2.28)
\]

The RHS of (2.27) can be expressed in terms of \( \bar{\Gamma}_k \) by noting that the connected two-point function

\[
G_{ij}(x, y) \equiv < \chi_i(x)\chi_j(y) > - \varphi_i(x)\varphi_j(y) = \frac{1}{\sqrt{\bar{g}(x)\bar{g}(y)}} \delta^{2W_k} \frac{\delta^2 \bar{\Gamma}_k}{\delta J^i(x) \delta J^j(y)} \quad (2.29)
\]

and

\[
\bar{\Gamma}_{k(2)}^{ij}(x, y) \equiv \frac{1}{\sqrt{\bar{g}(x)\bar{g}(y)}} \frac{\delta^2 \bar{\Gamma}_k}{\delta \varphi_i(x) \delta \varphi_j(y)} \quad (2.30)
\]
are inverse matrices in the sense that

\[
\int d^d y \sqrt{\bar{g}(y)} G_{ij}(x, y) \bar{\Gamma}^{(2)}_{k}(y, z) = \delta_{ij} \frac{\delta(x - z)}{\sqrt{\bar{g}(z)}} \tag{2.31}
\]

Here we used the shorthand notation \( \chi_i \equiv \{ h, C, \bar{C} \} \), \( J^i \equiv \{ t, \sigma, \bar{\sigma} \} \) and \( \varphi_i \equiv \{ \bar{h}, \xi, \bar{\xi} \} \). Thus one obtains the evolution equation

\[
\partial_t \Gamma_k[\bar{h}, \xi, \bar{\xi}; \beta, \tau; \bar{g}] = \frac{1}{2} \text{Tr} \left[ \left( \Gamma^{(2)}_k + \tilde{R}_k \right)^{-1}_{\bar{h}h} \left( \partial_t \tilde{R}_k \right)_{\bar{h}h} \right]
- \frac{1}{2} \text{Tr} \left[ \left\{ \left( \Gamma^{(2)}_k + \tilde{R}_k \right)^{-1}_{\xi\xi} - \left( \Gamma^{(2)}_k + \tilde{R}_k \right)^{-1}_{\xi\bar{\xi}} \right\} \left( \partial_t \tilde{R}_k \right)_{\xi\bar{\xi}} \right] \tag{2.32}
\]

If one evaluates the RHS of this equation in terms of position–space matrix elements then \( \Gamma^{(2)}_k \) is defined by a formula similar to (2.30) and the integration implied by “Tr” has to be interpreted as \( \int d^d x \sqrt{\bar{g}(x)} \). The matrix elements in the ghost sector are defined in terms of left derivatives, e.g.

\[
\left( \left( \Gamma^{(2)}_k \right)^{\nu y}_{\mu x} \right) = \frac{1}{\sqrt{\bar{g}(x)}} \frac{1}{\delta \xi^{\mu}(x)} \frac{1}{\sqrt{\bar{g}(y)}} \frac{\delta \Gamma_k}{\delta \xi^{\nu}(y)} \tag{2.33}
\]

For any cutoff which is qualitatively similar to (2.14) the traces on the RHS of eq.(2.32) are well convergent, both in the IR and the UV. By virtue of the factor \( \partial_t \tilde{R}_k \), the dominant contributions come from a narrow band of generalized momenta centered around \( k \). Large momenta are exponentially suppressed.

Solving the evolution equation (2.32) with the appropriate initial condition at the UV cutoff scale \( \Lambda \to \infty \) is tantamount to computing the original functional integral (2.2). In order to determine the correct initial value \( \Gamma_{\Lambda} \) we consider the following integral equation satisfied by \( \Gamma_k \):

\[
\exp \left\{ -\Gamma_k[\bar{h}, \xi, \bar{\xi}; \beta, \tau; \bar{g}] \right\} =
\int D h D C D \bar{C} \exp \left[ -\bar{S}[h, C, \bar{C}; \beta, \tau; \bar{g}] \right]
+ \int d^d x \left\{ \left( h_{\mu\nu} - \bar{h}_{\mu\nu} \right) \frac{\delta \Gamma_k}{\delta h_{\mu\nu}} + \left( C^\mu - \xi^\mu \right) \frac{\delta \Gamma_k}{\delta \xi^\mu} + \left( \bar{C}_\mu - \bar{\xi}_\mu \right) \frac{\delta \Gamma_k}{\delta \bar{\xi}_\mu} \right\}
\cdot \exp \left\{ -\Delta_k \tilde{S}[h - \bar{h}, C - \xi, \bar{C} - \bar{\xi}; \bar{g}] \right\} \tag{2.34}
\]
Here

$$\tilde{S} \equiv S + S_{gf} + S_{gh} - \int d^d x \sqrt{\tilde{g}} \{ \beta^{\mu \nu} \mathcal{L}_C(\tilde{g}_{\mu \nu} + \tilde{h}_{\mu \nu}) + \tau_{\mu} C^{\nu} \partial_\nu C^\mu \}$$  \hspace{1cm} (2.35)$$

is expressed in terms of the “microscopic” fields \((h, C, \tilde{C})\). Eq. (2.34) obtains by inserting the definition of \(\Gamma_k\) into (2.2) and using

$$\frac{\delta \tilde{\Gamma}_k}{\delta h_{\mu \nu}} = \sqrt{g} t^{\mu \nu}, \quad \frac{\delta \tilde{\Gamma}_k}{\delta C_\mu} = -\sqrt{g} \sigma^\mu, \quad \frac{\delta \tilde{\Gamma}_k}{\delta \xi_\mu} = -\sqrt{g} \bar{\sigma}_\mu$$  \hspace{1cm} (2.36)$$

The crucial observation is that for \(k \to \infty\) the last exponential in (2.34) becomes proportional to a \(\delta\)-functional which equates the quantum fields \((h, C, \tilde{C})\) to their classical counterparts:

$$e^{-\Delta_k S} \xrightarrow{k \to \infty} \delta[h - \bar{h}]\delta[C - \xi] \delta[\tilde{C} - \bar{\xi}]$$  \hspace{1cm} (2.37)$$

As a consequence, the effective average action at the UV cutoff reads\(^2\)

$$\Gamma_\Lambda[h, \xi, \bar{\xi}; \beta, \tau; \bar{g}] = S[\bar{g} + \bar{h}] + S_{gf}[\bar{h}; \bar{g}] + S_{gh}[h, \xi, \bar{\xi}; \bar{g}]$$  \hspace{1cm} (2.38)$$

$$- \int d^d x \sqrt{\bar{g}} \{ \beta^{\mu \nu} \mathcal{L}_\xi(\bar{g}_{\mu \nu} + \bar{h}_{\mu \nu}) + \tau_{\mu} \xi^\nu \partial_\nu \xi^\mu \}$$

It is this action \(\Gamma_\Lambda\) which has to be used as the initial condition for the evolution equation. We note that at the level of the functional \(\tilde{\Gamma}_k[g]\) eq.(2.38) boils down to

$$\tilde{\Gamma}_\Lambda[g_{\mu \nu}] = S[g_{\mu \nu}]$$  \hspace{1cm} (2.39)$$

As \(\Gamma_\Lambda^{(2)}\) involves derivatives with respect to \(g_{\mu \nu}\) at fixed \(\bar{g}_{\mu \nu}\) it is clear that the evolution equation cannot be formulated in terms of \(\tilde{\Gamma}_k\) alone, however.

Up to now we assumed that the fundamental action \(S\) is positive definite and the euclidean functional integral (2.2) makes sense as it stands. It is well known that this is not the case for the Einstein–Hilbert action, for example, because the conformal factor has a “wrong sign” kinetic term. Clearly it would be desirable to have an evolution equation which can be applied in such cases as well. It is quite remarkable therefore that the renormalization group equation (2.32), with a

\(^2\) Strictly speaking (2.38) is correct only up to local terms which at most change the bare parameters in \(S\). Because the value of the bare parameters has anyhow no physical significance we ignore these terms here.
properly chosen cutoff, is well–defined even if $S$ and $\Gamma_k$ are not positive definite. To see this, let us look at the first trace on the RHS of (2.32) and let us concentrate on the contribution of a fixed mode $\phi$ contained in the metric. We assume that $\phi$ is an eigenfunction of $\Gamma^{(2)}_k$ with eigenvalue $z_k p^2$ where $p^2$ is a positive eigenvalue of some covariant kinetic operator, typically of the form $-\bar{D}^2 + R$–terms. For theories with $S > 0$, the wave function renormalization $z_k$ is positive (at least for large $k$). In this case the general rule \cite{5,6} is to define the constant $Z_k$ in the cutoff $R_k$, eq.(2.13), as $Z_k = z_k$ because this guarantees that for the low–momentum modes the effective inverse propagators $\Gamma^{(2)} + R_k$ becomes $z_k(p^2 + k^2)$, as it should be.

The important question is how $Z_k$ should be chosen if $z_k$ is negative. If we continue to use $Z_k = z_k$, the evolution equation is perfectly well defined because the inverse propagator $-|z_k|(p^2 + k^2)$ never vanishes, and the traces of (2.32) are not suffering from any IR problems. In fact, if we write down the perturbative expansion for the functional trace, for instance, it is clear that all propagators are correctly cut off in the IR, and that loop momenta smaller than $k$ are suppressed. On the other hand, if we set $Z_k = -z_k$, then $-|z_k|(p^2 - k^2)$ introduces a spurious singularity at $p^2 = k^2$, and the cutoff fails to make the theory IR finite in this case.

At first sight the choice $Z_k = -z_k$ might have appeared more natural because only if $Z_k > 0$ the factor $\exp(-\Delta_k S) \sim \exp(-\int R_k \phi^2)$ is a damped exponential which suppresses the low momentum modes in the usual way. In this paper we shall nevertheless adopt the rule $Z = z_k$ for either sign of $z_k$. We shall see that at least for the Einstein–Hilbert truncation of section 4 the evolution equations are well defined and consistent even though it is difficult to give a meaning to the functional integral itself. In the case $Z_k = z_k < 0$ the factor $\exp(+\int |R_k| \phi^2)$ unavoidably becomes a growing exponential and it might seem that this enhances rather than suppresses the low momentum modes. However, as suggested by the perturbative argument above, this conclusion is too naive probably. Moreover, if one invokes the usual prescription of rotating the contour of integration over $\phi$ so that it is parallel to the imaginary axis, both the kinetic term and the cutoff lead to damped exponentials.

Furthermore, it is important to note that the constructions in this section can be repeated for metrics on Lorentzian spacetimes. Then one deals with oscillating
exponentials $e^{iS}$, and for arguments like the one leading to eq. (2.37) one has to employ the Riemann-Lebesgue lemma. Apart from the obvious substitutions $\Gamma_k \to -i\Gamma_k$, $R_k \to -iR_k$, the evolution equation remains unaltered. For $Z_k = z_k$ it has all the desired features, and $z_k < 0$ seems not to pose any special problem.

3 Modified Ward Identities and Consistent Truncations

We mentioned already that the classical action plus the gauge fixing and ghost terms are invariant under the BRS transformations (2.17). Therefore the BRS variation of the total action $S_{\text{tot}} \equiv S + S_{\text{gf}} + S_{\text{gh}} + \Delta_k S + S_{\text{sources}}$ receives contributions only from the cutoff and the source terms. If we apply a BRS transformation to the integral defining $W_k$ and assume that the measure is invariant we obtain

$$< \delta_\varepsilon S_{\text{sources}} + \delta_\varepsilon \Delta_k S > = 0 \quad (3.1)$$

where

$$< \mathcal{O} > = e^{-W_k} \int DhD\mathcal{C}D\bar{\mathcal{C}} \mathcal{O} e^{-S_{\text{tot}}} \quad (3.2)$$

Our goal is to convert (3.1) to a statement about the average action $\Gamma_k$. Because the BRS transformation (2.17) is off-shell nilpotent when acting on $h_{\mu\nu}$ and on $C^\mu$ (but not on $\bar{C}_\mu$) one has

$$\delta_\varepsilon S_{\text{sources}} = -\varepsilon \kappa^{-2} \int d^d x \sqrt{\bar{g}(x)} \left\{ t^{\mu\nu} \mathcal{L}_C (\bar{g}_{\mu\nu} + h_{\mu\nu}) \right. - \bar{\sigma}_\mu C^{\mu} \partial_\nu C^\mu - \kappa \alpha^{-1} \sigma^\mu F_\mu (\bar{g}, h) \}

\quad (3.3)$$

If we take the expectation value of (3.3) and express $W_k$ in terms of $\Gamma_k$ we find

$$< \delta_\varepsilon S_{\text{source}} >= \frac{\varepsilon}{\kappa^2} \int d^d x \frac{1}{\sqrt{\bar{g}(x)}} \left\{ \frac{\delta \Gamma'_k}{\delta h_{\mu\nu}} \frac{\delta \Gamma'_k}{\delta \beta^{\mu\nu}} + \frac{\delta \Gamma'_k}{\delta \xi^\mu} \frac{\delta \Gamma'_k}{\delta \tau_{\mu}} \right\} + \frac{\varepsilon}{\kappa^2} \bar{Y}_k \quad (3.4)$$

with

$$\bar{Y}_k \equiv \int d^d x \left\{ \frac{1}{\sqrt{\bar{g}}} \left( \frac{\delta \Delta_k S}{\delta h_{\mu\nu}} \frac{\delta \Gamma'_k}{\delta \beta^{\mu\nu}} + \frac{\delta \Delta_k S}{\delta \xi^\mu} \frac{\delta \Gamma'_k}{\delta \tau_{\mu}} \right) - \sqrt{2} \kappa \frac{\delta F_\mu (\bar{g}, h)}{\alpha} R^g_{\mu} \xi^\mu \right\} \quad (3.5)$$

Here we defined

$$\Gamma'_k \equiv \Gamma_k - S_{\text{gf}}[\bar{h}; \bar{g}] \quad (3.6)$$
and we exploited the equation of motion $\langle \delta S_{\text{tot}} / \delta \bar{C}_\mu \rangle = 0$ which can be cast in the form

$$
\left[ \frac{1}{\sqrt{g(x)}} \frac{\delta}{\delta \xi_\mu(x)} - \sqrt{2} g^{\mu\nu} F_{\nu}^\sigma \frac{1}{\sqrt{g(x)}} \frac{\delta}{\delta \beta^\sigma(x)} \right] \Gamma_k [\bar{h}, \xi, \bar{\xi}; \beta, \tau; \bar{g}] = 0 \quad (3.7)
$$

The variation of the cutoff terms gives rise to

$$
\langle \delta \varepsilon \Delta_k S \rangle = - \frac{\varepsilon}{\kappa^2} \left( Y_k + \bar{Y}_k \right) \quad (3.8)
$$

with

$$
Y_k \equiv \kappa^2 \text{Tr} \left[ (R_{k}^{\text{grav})}_{\mu}^\nu \sigma \left( \Gamma_{k}^{(2)}_{\mu} + \bar{R}_k \right)^{-1} \frac{\delta^2 \Gamma_k}{\sqrt{g} \delta \varphi} \sqrt{\bar{g}} \delta \beta_{\mu\nu} \right] - \sqrt{2} \text{Tr} \left[ R_{k}^{\text{gh}_{\mu}} \left( \Gamma_{k}^{(2)}_{\mu} + \bar{R}_k \right)^{-1} \frac{\delta^2 \Gamma_k}{\sqrt{g} \delta \varphi} \sqrt{\bar{g}} \delta \tau_{\mu} \right] + 2 \alpha^{-1} \kappa^2 \text{Tr} \left[ R_{k}^{\text{gh}_{\mu}} \left( \Gamma_{k}^{(2)}_{\mu} + \bar{R}_k \right)^{-1} \right] \quad (3.9)
$$

where $\varphi \equiv \{ \bar{h}, \xi, \bar{\xi} \}$ is summed over. From (3.4) and (3.8) we obtain the Ward identities in their final form:

$$
\int d^d x \frac{1}{\sqrt{g}} \left\{ \frac{\delta \Gamma'_k}{\delta h_{\mu
u}} \frac{\delta \Gamma'_k}{\delta \beta_{\mu
u}} + \frac{\delta \Gamma'_k}{\delta \xi_{\mu}} \frac{\delta \Gamma'_k}{\delta \gamma_{\mu}} \right\} = Y_k \quad (3.10)
$$

Eq. (3.10) has to be compared to the ordinary gravitational Ward identities [23] which are similar to (3.10) but with a vanishing RHS. In fact, the contribution $Y_k$ is due to the cutoff and therefore it vanishes in the limit $k \to 0$ because $R_k \sim k^2 \to 0$ in this limit. Hence the standard effective action $\lim_{k \to 0} \Gamma_k$ is guaranteed to obey its usual Ward identities, and BRS invariance is restored for $k \to 0$.

Because the Ward identity (3.10) is derived from the same functional integral as the evolution equation, it is automatically satisfied for the exact solution of the evolution equation. For approximate solutions of the evolution equation their consistency with the Ward identity is not guaranteed, and one may even use (3.10) to judge the quality of the approximation [12, 19].

The most important strategy for finding approximate (but still nonperturbative) solutions to the evolution equation is to truncate the space of action functionals. Typically one works on a finite–dimensional subspace parametrized by only a few generalized couplings. As a first step towards such a truncation one
can try to neglect the evolution of the ghost action. This amounts to making an
ansatz of the following form:

$$
\Gamma_k[g, \bar{g}, \xi, \bar{\xi}; \beta, \tau] = \bar{\Gamma}_k[g] + \hat{\Gamma}_k[g, \bar{g}] + S_{gf}[g - \bar{g}; \bar{g}] + S_{gh}[g - \bar{g}, \xi, \bar{\xi}; \bar{g}] 
$$
(3.11)

$$
- \int d^d x \sqrt{g} \left\{ \beta^{\mu \nu} L_\xi g_{\mu \nu} + \tau_\mu \xi^\nu \partial_\nu \xi^\mu \right\}
$$

In (3.11) we pulled out the classical $S_{gf}$ and $S_{gh}$ from $\Gamma_k$, and also the coupling
to the BRS variations has the same form as in the bare action. The remaining
functional depends on both $g_{\mu \nu}$ and $\bar{g}_{\mu \nu}$. It is further decomposed as $\bar{\Gamma}_k + \hat{\Gamma}_k$
where $\bar{\Gamma}_k$ is defined as in (2.26) and $\hat{\Gamma}_k$ contains the deviations for $\bar{g} \neq g$. Hence
by definition

$$
\hat{\Gamma}_k[g, g] = 0
$$
(3.12)

$\hat{\Gamma}_k$ can be viewed as a quantum correction the gauge fixing term which also van-
ishes for $\bar{g} = g$. The ansatz (3.11) satisfies the initial condition (2.38) if

$$
\bar{\Gamma}_\Lambda = S, \quad \hat{\Gamma}_\Lambda = 0
$$
(3.13)

and it satisfies the quantum equation of motion (3.7) exactly. Eq. (3.13) suggests
to set $\hat{\Gamma}_k = 0$ for all $k$ in a first approximation. In this case it can be checked
that if the ansatz (3.11) is inserted into the Ward identity (3.10) its LHS vanishes
identically. Including $\hat{\Gamma}_k$ the Ward identity assumes the form

$$
\int d^d x L_\xi g_{\mu \nu} \frac{\delta \hat{\Gamma}_k[g, \bar{g}]}{\delta g_{\mu \nu}(x)} = -Y_k
$$
(3.14)

We see that $\hat{\Gamma}_k = 0$ is a good approximation provided we may neglect $Y_k$. The
traces which define $Y_k$ amount to loop integrals, and if we think in terms of a
loop expansion $Y_k$ is certainly a higher loop effect and may be neglected in a
first approximation. At the nonperturbative level one can still try to set $\hat{\Gamma}_k = 0$
and investigate the consequences in concrete examples. In Yang–Mills theory the
analogous truncation has led to rather encouraging results already [5, 6, 9]. In
the next section we shall perform an explicit calculation in this approximation.

If one inserts the ansatz (3.11) into the evolution equation (2.32) one finds
the following equation for the evolution of $\Gamma_k$ in the subspace spanned by the
ansatz:
\[ \partial_t \Gamma_k[g, \bar{g}] = \frac{1}{2} \text{Tr} \left[ \left( \kappa^{-2} \Gamma^{(2)}_k[g, \bar{g}] + R_{k}^{\text{grav}}[\bar{g}] \right)^{-1} \partial_t R_{k}^{\text{grav}}[\bar{g}] \right] - \text{Tr} \left[ \left( -\mathcal{M}[g, \bar{g}] + R_{k}^{\text{gh}}[\bar{g}] \right)^{-1} \partial_t R_{k}^{\text{gh}}[\bar{g}] \right] \] (3.15)

This equation is written down in terms of
\[ \Gamma_k[g, \bar{g}] = \Gamma_k[g, \bar{g}, 0, 0; 0, 0] = \Gamma_k[g] + S_{gf}[g - \bar{g}; \bar{g}] + \tilde{\Gamma}_k[g, \bar{g}] \] (3.16)

\( \Gamma^{(2)}_k \) is the Hessian of \( \Gamma_k[g, \bar{g}] \) with respect to \( g_{\mu\nu} \) at fixed \( \bar{g}_{\mu\nu} \). For the harmonic coordinate condition, the classical kinetic term of the ghosts, \( \mathcal{M} \), is given by eq.(2.11).

## 4 The Einstein–Hilbert Truncation

In this section we illustrate the use of eq.(3.15) by means of a simple example. At the UV scale \( \Lambda \) we start from the classical Einstein–Hilbert action in \( d \) dimensions,
\[ S = \frac{1}{16\pi \bar{G}} \int d^d x \sqrt{\bar{g}} \left\{ -R(g) + 2\bar{\lambda} \right\}, \] (4.1)
and we evolve it down to smaller scales \( k < \Lambda \). For the time being we shall not try to send \( \Lambda \) to infinity, so the nonrenormalizability of the theory is not an issue here. We are going to use a truncation which replaces in (4.1) the bare Newton constant \( \bar{G} \) and the bare cosmological constant \( \bar{\lambda} \) by \( k \)-dependent functions
\[ G_k \equiv Z_{N_k}^{-1} \bar{G} \] (4.2)
and \( \bar{\lambda}_k \), respectively:
\[ \Gamma_k[g, \bar{g}] = 2\kappa^2 Z_{N_k} \int d^d x \sqrt{g} \left\{ -R(g) + 2\bar{\lambda}_k \right\} + \kappa^2 Z_{N_k} \int d^d x \sqrt{g} g^{\mu\nu} \left( F^{\alpha\beta}_\mu g_{\alpha\beta} \right) \left( F^{\rho\sigma}_\nu g_{\rho\sigma} \right) \] (4.3)
This ansatz is of the form (3.16) with $\tilde{\Gamma}_k$ neglected and the classical gauge fixing term given by (2.4) with (2.8), (2.9) and $\alpha = 1/Z_{Nk}$. (Note that $\mathcal{F}^{\alpha\beta}_\mu g_{\alpha\beta} = \mathcal{F}^{\alpha\beta}_\mu \tilde{h}_{\alpha\beta}$ because $\bar{D}_\mu g_{\alpha\beta} = 0$.) In order to determine the functions $Z_{Nk}$ and $\bar{\lambda}_k$ we have to project the evolution equation on the space spanned by the operators $\sqrt{g}$ and $\sqrt{gR}$. After having inserted the ansatz into the evolution equation we may set $\bar{g}_{\mu\nu} = g_{\mu\nu}$ so that the gauge fixing term in (4.3) vanishes. The LHS of the evolution equation reads then

$$\partial_t \Gamma_k[g, g] = 2\kappa^2 \int d^d x \sqrt{g} \left[ -R(g) \partial_t Z_{Nk} + 2 \partial_t \left( Z_{Nk} \bar{\lambda}_k \right) \right] \quad (4.4)$$

On the RHS of (3.15) we have to perform a derivative expansion and retain only the terms proportional to $\int \sqrt{g}$ and $\int \sqrt{gR}$. Equating the result to (4.4) we can read off the system of ordinary differential equations for $Z_{Nk}$ and $\bar{\lambda}_k$. They have to be solved subject to the initial conditions $Z_{NA} = 1$ and $\bar{\lambda}_A = \bar{\lambda}$. In this manner the renormalization group flow in the space of all action functionals is projected onto the 2–dimensional subspace parametrized by $\tilde{G}$ and $\bar{\lambda}$.

In the evolution equation we need the second functional derivative of $\Gamma_k[g, \bar{g}]$ at fixed $\bar{g}_{\mu\nu}$. We expand

$$\Gamma_k[\bar{g} + \bar{h}, \bar{g}] = \Gamma_k[\bar{g}, \bar{g}] + O(\bar{h}) + \Gamma_k^{\text{quad}}[\bar{h}; \bar{g}] + O(\bar{h}^3) \quad (4.5)$$

and we find for the piece which is quadratic in $\bar{h}_{\mu\nu}$:

$$\Gamma_k^{\text{quad}}[\bar{h}; \bar{g}] = Z_{Nk} \kappa^2 \int d^d x \sqrt{\bar{g}} \bar{h}_{\mu\nu} \left[ -K^{\mu\nu}_{\rho\sigma} \bar{D}^2 + U^{\mu\nu}_{\rho\sigma} \right] \bar{h}^{\rho\sigma} \quad (4.6)$$

Here indices are raised and lowered with $\bar{g}_{\mu\nu}$, and the tensors $K$ and $U$ are given by

$$K^{\mu\nu}_{\rho\sigma} = \frac{1}{4} \left[ \delta^\mu_\rho \delta^\nu_\sigma + \delta^\mu_\sigma \delta^\nu_\rho - \bar{g}^{\mu\nu} \bar{g}_{\rho\sigma} \right] \quad (4.7)$$

and

$$U^{\mu\nu}_{\rho\sigma} = \frac{1}{4} \left[ \delta^\mu_\rho \delta^\nu_\sigma + \delta^\mu_\sigma \delta^\nu_\rho - \bar{g}^{\mu\nu} \bar{g}_{\rho\sigma} \right] \left( \bar{R} - 2\bar{\lambda}_k \right) + \frac{1}{2} \left[ \bar{g}^{\mu\nu} \bar{R}_{\rho\sigma} + \bar{g}_{\rho\sigma} \bar{R}^{\mu\nu} \right] - \frac{1}{4} \left[ \delta^\mu_\rho \bar{R}_\nu^{\sigma} + \delta^\mu_\sigma \bar{R}_\nu^{\rho} + \delta^\nu_\rho \bar{R}_\sigma^{\mu} + \delta^\nu_\sigma \bar{R}_\rho^{\mu} \right] - \frac{1}{2} \left[ \bar{R}^{\nu}_{\rho \sigma} + \bar{R}^{\nu}_{\sigma \rho} \right] \quad (4.8)$$

In eq.(4.8) all geometrical quantities are constructed from the background metric.\footnote{We use the conventions $R^{\nu}_{\rho\mu\nu} = -\partial_\gamma \Gamma^\gamma_{\mu\rho} + \ldots$, $R_{\mu\nu} = R^\sigma_{\mu\sigma\nu}$ and $R = g^{\mu\nu} R_{\mu\nu}$.}

In order to partially diagonalize the quadratic form (4.6) we write $\bar{h}_{\mu\nu}$ as the sum
of a traceless tensor $\tilde{h}_{\mu\nu}$ and a trace part involving $\phi \equiv \bar{g}^{\mu\nu} \tilde{h}_{\mu\nu}$:

$$\tilde{h}_{\mu\nu} = \hat{h}_{\mu\nu} + d^{-1} \bar{g}_{\mu\nu} \phi \quad \bar{g}^{\mu\nu} \tilde{h}_{\mu\nu} = 0 \quad (4.9)$$

As a consequence, eq.(4.6) becomes

$$\Gamma_{\text{quad}}^{\mu\nu} = Z_{Nk} \kappa^2 \int d^4 x \sqrt{\bar{g}} \left\{ \frac{1}{2} \hat{h}_{\mu\nu} \left[ -\bar{D}^2 - 2\bar{\lambda}_k + \bar{R} \right] \hat{h}^{\mu\nu} \right. \\
- \left( \frac{d-2}{4d} \right) \phi \left[ -\bar{D}^2 - 2\bar{\lambda}_k + \frac{d-4}{d} \bar{R} \right] \phi \\
- \bar{R}_{\mu\nu} \hat{h}^{\nu\rho} \hat{h}^\rho_{\mu} + \bar{R}_{\alpha\beta\mu\nu} \hat{h}^{\beta\nu} \hat{h}^{\alpha\mu} + \frac{d-4}{d} \phi \bar{R}_{\mu\nu} \hat{h}^{\mu\nu} \right\} \quad (4.10)$$

The equations for $Z_{Nk}$ and $\bar{\lambda}_k$ obtain by comparing the coefficients of $\int \sqrt{g}$ and $\int \sqrt{gR}$ on both sides of the evolution equation at $\bar{g}_{\mu\nu} = g_{\mu\nu}$. For this purpose we may insert an arbitrary family of metrics $g_{\mu\nu}$ which is general enough to identify the terms $\int \sqrt{g}$ and $\int \sqrt{gR}$ and to distinguish them from higher order terms in the derivative expansion, such as $\int \sqrt{g}R^2$ or $\int \sqrt{g}R^{\mu\nu} D_\mu D_\nu R$, for instance. We exploit this freedom by assuming that $\bar{g}_{\mu\nu}$ corresponds to a maximally symmetric space, i.e., that

$$\bar{R}_{\mu\nu} = \frac{1}{d} \bar{g}_{\mu\nu} \bar{R} \quad (4.11)$$

From now on the curvature scalar $\bar{R}$ parametrizes the family of metrics inserted, and it should be regarded as an externally prescribed number rather than a functional of the metric. For a maximally symmetric background the quadratic action boils down to

$$\Gamma_{\text{quad}}^{\mu\nu} = \frac{1}{2} Z_{Nk} \kappa^2 \int d^4 x \left\{ \hat{h}_{\mu\nu} \left[ -\bar{D}^2 - 2\bar{\lambda}_k + C_T \bar{R} \right] \hat{h}^{\mu\nu} \right. \\
- \left( \frac{d-2}{2d} \right) \phi \left[ -\bar{D}^2 - 2\bar{\lambda}_k + C_S \bar{R} \right] \phi \right\} \quad (4.12)$$

with

$$C_T \equiv \frac{d(d-3) + 4}{d(d-1)} \quad , \quad C_S \equiv \frac{d-4}{d} \quad (4.13)$$
Before continuing we have to specify the precise form of the cutoff operators $R_{k}^{\text{grav}}$ and $R_{k}^{\text{gh}}$ to be used in the evolution equation (3.15). Both of them have the structure (2.13) whereby $Z_{k}$ should be adjusted in such a way that for every low–momentum mode the cutoff combines with the kinetic term of this mode to $-\bar{D}^2 + k^2$ times a constant. Looking at (4.12) we see that the respective kinetic terms for $\hat{h}_{\mu\nu}$ and $\phi$ differ by a factor of $-(d-2)/2d$. This suggests the following choice:

$$(Z_{k}^{\text{grav}})^{\mu\nu\rho\sigma}_{\mu\nu\rho\sigma} = [(I - P_{\phi})^{\mu\nu\rho\sigma} - \frac{d - 2}{2d} P_{\phi}^{\mu\nu\rho\sigma}] Z_{Nk} \quad (4.14)$$

Here

$$(P_{\phi})_{\mu\nu}^{\rho\sigma} = d^{-1} g_{\mu\nu} g^{\rho\sigma} \quad (4.15)$$

is the projector on the trace part of the metric. For the traceless tensor (1.14) coincides with (2.13) for $Z_{k}^{\text{grav}} = Z_{Nk}$, and for $\phi$ the different relative normalization is taken into account. Thus we obtain in the $\hat{h}$ and the $\phi$–sector, respectively:

$$\left(\kappa^{-2} \Gamma^{(2)}_{k}[g, g] + R_{k}^{\text{grav}}\right)_{\hat{h}} = Z_{Nk} \left[-D^2 + k^2 R^{(0)}(-D^2/k^2) - 2\lambda_{k} + C_{T} R\right],$$

$$\left(\kappa^{-2} \Gamma^{(2)}_{k}[g, g] + R_{k}^{\text{grav}}\right)_{\phi} = -\frac{d - 2}{2d} Z_{Nk} \left[-D^2 + k^2 R^{(0)}(-D^2/k^2) - 2\lambda_{k} + C_{S} R\right] \quad (4.16)$$

From now on we may set $\bar{g} = g$ and we omit the bars from the metric and the curvature.

The last missing ingredient for the evolution equation is the Faddeev–Popov operator. From (2.11) one obtains at $\bar{g} = g$

$$\mathcal{M}[g, g]_{\mu\nu} = \delta_{\nu}^{\mu} D^2 + R_{\mu}^{\nu} = -\delta_{\nu}^{\mu} \left[-D^2 + C_{V} R\right] \quad (4.17)$$

with

$$C_{V} \equiv -\frac{1}{d} \quad (4.18)$$

In the second part of (4.17) we used (4.11) for a maximally symmetric background. Since we did not take into account any renormalization effects in the ghost action we set $Z_{k}^{\text{gh}} \equiv 1$ in $R_{k}^{\text{gh}}$ and obtain

$$-\mathcal{M} + R_{k}^{\text{gh}} = -D^2 + k^2 R^{(0)}(-D^2/k^2) + C_{V} R \quad (4.19)$$
Let us write $S_k(R)$ for the RHS of the renormalization group equation (b.15) with $\bar{g} = g$. Inserting (4.16) and (4.19) there we arrive at

$$S_k(R) = \text{Tr}_T \left[ \mathcal{N} (\mathcal{A} + C_T R)^{-1} \right] + \text{Tr}_S \left[ \mathcal{N} (\mathcal{A} + C_S R)^{-1} \right] - 2 \text{Tr}_V \left[ \mathcal{N}_0 (\mathcal{A}_0 + C_V R)^{-1} \right]$$

with

$$\mathcal{A} \equiv - D^2 + k^2 R^{(0)} (- D^2 / k^2) - 2 \lambda_k$$

$$\mathcal{N} \equiv (2Z_{Nk})^{-1} \partial_t \left[ Z_{Nk} k^2 R^{(0)} (- D^2 / k^2) \right]$$

$$= \left[ 1 - \frac{1}{2} \eta_N(k) \right] k^2 R^{(0)} (- D^2 / k^2) + D^2 R^{(0)}' (- D^2 / k^2)$$

where a prime denotes the derivative with respect to the argument and

$$\eta_N(k) \equiv - \partial_t \ln Z_{Nk}$$

is the anomalous dimension of the operator $\sqrt{g} R$. The operators $\mathcal{N}_0$ and $\mathcal{A}_0$ are defined similarly to (4.21) but with $\lambda = 0$ and $Z_{Nk} = 1$, i.e., $\eta_N(k) = 0$. Eq.(4.20) involves traces of functions of the covariant Laplacian $D^2 \equiv g^{\mu \nu} D_\mu D_\nu$ acting on traceless symmetric tensors ("T"), scalars ("S") and vectors ("V"). Because we need only the zeroth and the first order in the curvature scalar we can expand

$$S_k(R) = \text{Tr}_T \left[ \mathcal{N} \mathcal{A}^{-1} \right] + \text{Tr}_S \left[ \mathcal{N} \mathcal{A}^{-1} \right] - 2 \text{Tr}_V \left[ \mathcal{N}_0 \mathcal{A}_0^{-1} \right] - R \left( C_T \text{Tr}_T[\mathcal{N} \mathcal{A}^{-2}] + C_S \text{Tr}_S[\mathcal{N} \mathcal{A}^{-2}] - 2 C_V \text{Tr}_V[\mathcal{N}_0 \mathcal{A}_0^{-2}] \right) + O(R^2)$$

The traces in (4.23) can be evaluated by taking advantage of the heat kernel expansion

$$\text{Tr} \left[ e^{-i s D^2} \right] = \left( \frac{i}{4 \pi s} \right)^{d/2} \text{tr}(I) \int d^d x \sqrt{g} \left\{ 1 - \frac{1}{6} i s R + O(R^2) \right\}$$

Here $I$ denotes the unit matrix of the space of fields on which $D^2$ acts. Hence
tr(I) is the number of independent field components and in particular

\begin{align*}
\text{tr}_S(I) &= 1 \\
\text{tr}_V(I) &= d \\
\text{tr}_T(I) &= \frac{1}{2}(d - 1)(d + 2)
\end{align*}

(4.25)

Considering an arbitrary function \( W \) with a Fourier transform \( \tilde{W} \), the expansion of the trace

\[ \text{Tr}[W(-D^2)] = \int_{-\infty}^{\infty} ds \tilde{W}(s) \text{Tr}\left[e^{-isD^2}\right] \quad (4.26) \]

is given by

\[ \text{Tr}[W(-D^2)] = (4\pi)^{-d/2}\text{tr}(I) \left\{ Q_{d/2}[W] \int d^d x \sqrt{g} \\ + \frac{1}{6}Q_{d/2-1}[W] \int d^d x \sqrt{g}R + O(R^2) \right\} \quad (4.27) \]

with

\[ Q_n[W] \equiv \int_{-\infty}^{\infty} ds (-is)^n\tilde{W}(s) \quad (4.28) \]

Reexpressing (4.28) in terms of \( W \) leads to the Mellin transform \((n > 0)\)

\[ Q_0[W] = W(0) \quad (4.29) \]

\[ Q_n[W] = \frac{1}{\Gamma(n)} \int_0^{\infty} dz z^{n-1}W(z) \]

The next step is to use (4.27) in order to evaluate (4.23) and to combine \( S(R) \) with the LHS of the evolution equation, eq.(4.4). From the coefficients of \( f \sqrt{g} \) we can read off the following equation

\[ \partial_t \left(Z_{Nk} \tilde{\lambda}_k\right) = (4\kappa^2)^{-1}(4\pi)^{-d/2} \left\{ \text{tr}_T(I)Q_{d/2}[\mathcal{N}/\mathcal{A}] \\ + \text{tr}_S(I)Q_{d/2}[\mathcal{N}/\mathcal{A}] - 2\text{tr}_V(I)Q_{d/2}[\mathcal{N}_0/\mathcal{A}_0] \right\} \quad (4.30) \]
Likewise $\sqrt{g} R$ gives rise to

$$
\partial_t Z_{Nk} = -(12\kappa^2)^{-1}(4\pi)^{-d/2} \left[ \text{tr}_T(I) \left\{ Q_{d/2-1}[N/A] - 6C_T Q_{d/2}[N/A^2] \right\} 
+ \text{tr}_S(I) \left\{ Q_{d/2-1}[N/A] - 6C_S Q_{d/2}[N/A^2] \right\} 
- 2\text{tr}_V(I) \left\{ Q_{d/2-1}[N_0/A_0] - 6C_V Q_{d/2}[N_0/A_0^2] \right\} \right] \quad (4.31)
$$

In (4.30) and (4.31), $N$ and $A$ are considered $c$-number functions of $z$ which replaces $-D^2$ in (4.21). For every cutoff $R(0)$ we define the functions ($p = 1, 2, \ldots$)

$$
\Phi_n^p(w) = \frac{1}{\Gamma(n)} \int_0^\infty dz \ z^{n-1} \frac{R^{(0)}(z) - y R^{(0)'}(z)}{[z + R^{(0)}(z) + w]^p}
$$

$$
\bar{\Phi}_n^p(w) = \frac{1}{\Gamma(n)} \int_0^\infty dz \ z^{n-1} \frac{R^{(0)}(z)}{[z + R^{(0)}(z) + w]^p}
$$

for $n > 0$, and

$$
\Phi_0^p(w) = \bar{\Phi}_0^p(w) = (1 + w)^{-p}
$$

In terms of the $\Phi$'s, eq. (4.30) assumes the form

$$
\partial_t (Z_{Nk} \bar{\lambda}_k) = (16\kappa^2)^{-1}(4\pi)^{-d/2} k^d \left[ 2d(d+1) \Phi_{d/2}^1(-2\bar{\lambda}_k/k^2) - 8d \Phi_{d/2}^1(0) 
- d(d+1) \eta_N \bar{\Phi}_{d/2}^1(-2\bar{\lambda}_k/k^2) \right] \quad (4.34)
$$

and (4.31) becomes

$$
\partial_t Z_{Nk} = -(24\kappa^2)^{-1}(4\pi)^{-d/2} k^{d-2} \cdot \left[ d(d+1) \left\{ \Phi_{d/2-1}^1(-2\bar{\lambda}_k/k^2) - \frac{1}{2} \eta_N \Phi_{d/2-1}^1(-2\bar{\lambda}_k/k^2) \right\} 
- 6d(d-1) \left\{ \Phi_{d/2}^2(-2\bar{\lambda}_k/k^2) - \frac{1}{2} \eta_N \bar{\Phi}_{d/2}^2(-2\bar{\lambda}_k/k^2) \right\} 
- 4d \Phi_{d/2-1}^1(0) - 24 \Phi_{d/2}^2(0) \right] \quad (4.35)
$$

---

4 Actually eq. (4.33) follows from (4.32) in the limit $n \searrow 0$. 
Let us introduce the dimensionless, renormalized Newton constant

$$g_k \equiv k^{d-2} G_k \equiv k^{d-2} Z_{Nk}^{-1} \tilde{G} \quad (4.36)$$

and the dimensionless cosmological constant

$$\lambda_k \equiv k^{-2} \bar{\lambda}_k \quad (4.37)$$

Here $G_k \equiv Z_{Nk}^{-1} \tilde{G}$ is the dimensionful renormalized Newton constant at scale $k$. The evolution of $g_k$ is governed by the equation

$$\partial_t g_k = [d - 2 + \eta_N(k)] g_k \quad (4.38)$$

From (4.37) we obtain for the anomalous dimension $\eta_N(k)$:

$$\eta_N(k) = g_k B_1(\lambda_k) + \eta_N(k) g_k B_2(\lambda_k) \quad (4.39)$$

with

$$B_1(\lambda_k) \equiv \frac{1}{3} (4\pi)^{1-d/2} \left[ d(d+1) \Phi_{d/2-1}^1(-2\lambda_k) - 6d(d-1) \Phi_{d/2}^2(-2\lambda_k) \right. $$

$$\left. - 4d \Phi_{d/2-1}^1(0) - 24 \Phi_{d/2}^2(0) \right] \quad (4.40)$$

$$B_2(\lambda_k) \equiv -\frac{1}{6} (4\pi)^{1-d/2} \left[ d(d+1) \tilde{\Phi}_{d/2-1}^1(-2\lambda_k) - 6d(d-1) \tilde{\Phi}_{d/2}^2(-2\lambda_k) \right]$$

We can solve (4.39) for the anomalous dimension in terms of $g_k$ and $\lambda_k$:

$$\eta_N = \frac{g_k B_1(\lambda_k)}{1 - g_k B_2(\lambda_k)} \quad (4.41)$$

The scale derivative of $\lambda_k$ is related to (4.34) according to

$$\partial_t \lambda_k = -(2 - \eta_N) \lambda_k + 32\pi g_k \kappa^2 k^{-d} \partial_t (Z_{Nk} \bar{\lambda}_k) \quad (4.42)$$

so that

$$\partial_t \lambda_k = -(2 - \eta_N) \lambda_k + \frac{1}{2} g_k (4\pi)^{1-d/2} \cdot \left[ 2d(d+1) \Phi_{d/2}^1(-2\lambda_k) - 8d \Phi_{d/2}^1(0) - d(d+1) \eta_N \tilde{\Phi}_{d/2}^1(-2\lambda_k) \right] \quad (4.43)$$
Eqs. (4.38) and (4.43) with (4.41) is the set of differential equations we wanted to derive. Once the initial values \( g_\Lambda \) and \( \lambda_\Lambda \) are given, it determines the value of the running Newton’s constant and cosmological constant at any scale \( k \leq \Lambda \). Although they were derived from a relatively simple truncation, the above evolution equations encapsulate nonperturbative effects which go beyond a simple one-loop calculation. This is particularly obvious if one expands for instance (4.41) for small values of \( g_k \):

\[
\eta_N = g_k B_1(\lambda_k) \left[ 1 + g_k B_2(\lambda_k) + g_k^2 B_2^2(\lambda_k) + \cdots \right]
\]

(4.44)

We observe that \( \eta_N \) receives contributions from arbitrarily high orders of perturbation theory.

5 Running Newton’s Constant and Cosmological Constant

5.1 Near two dimensions

In \( d = 2 \) dimensions \( \int \sqrt{g} R \) is a topological invariant proportional to the Euler number and the quantum theory under consideration has at most finitely many (topological) degrees of freedom. In \( d = 2 + \varepsilon \) dimensions, on the other hand, one finds a dynamically nontrivial theory with a nonzero \( \beta \)-function for \( g_k \) [24, 25, 26]:

\[
\partial_t g_k = [\varepsilon + \eta_N] g_k
\]

(5.1)

Gravity in \( 2+\varepsilon \) dimensions provides an interesting laboratory for a first test of the evolution equation because here the conformal factor of the metric can have both a conventional (\( \varepsilon < 0 \)) and a “wrong–sign” (\( \varepsilon > 0 \)) kinetic term, see eq.(4.12).

The anomalous dimension has a power series expansion

\[
\eta_N = \eta_N^{(0)} + \eta_N^{(1)} \varepsilon + \eta_N^{(2)} \varepsilon^2 + \ldots
\]

(5.2)

and therefore

\[
\partial_t g_k = \left[ (1 + \eta_N^{(1)}) \varepsilon + \eta_N^{(0)} \right] g_k + O(\varepsilon^2)
\]

(5.3)
Expanding the functions (4.40) as $B_{1,2} = B_{1,2}^{(0)} + B_{1,2}^{(1)} \varepsilon + \ldots$ one has

$$
\eta_{N}^{(0)} = \frac{g_k B_1^{(0)}}{1 - g_k B_2^{(0)}}
$$

$$
\eta_{N}^{(1)} = \frac{g_k B_1^{(1)}}{1 - g_k B_2^{(0)}} + \frac{g_k^2 B_1^{(0)} B_2^{(1)}}{(1 - g_k B_2^{(0)})^2}
$$

(5.4)

The lowest order terms are

$$
B_1^{(0)}(\lambda_k) = 2(1 - 2\lambda_k)^{-1} - 4\Phi_1^2(-2\lambda_k) - \frac{32}{3}
$$

(5.5)

$$
B_2^{(0)}(\lambda_k) = 2\Phi_1^2(-2\lambda_k) - (1 - 2\lambda_k)^{-1}
$$

We remark that for vanishing cosmological constant, $B_1^{(0)}$ is a universal quantity, i.e., it does not depend on the precise form of $R^{(0)}$:

$$
B_1^{(0)}(0) = -\frac{38}{3}
$$

(5.6)

The reason is that the integrand in the integral representation of $\Phi_1^2(0)$ equals the derivative of $z(z + R^{(0)}(z))^{-1}$; hence it is sufficient to know that $R^{(0)}$ is bounded everywhere in order to establish that

$$
\Phi_1^2(0) = 1
$$

(5.7)

Unlike $\Phi_1^2(0)$, $\Phi_1^2(\lambda_k)$ is sensitive to the shape of $R^{(0)}$ even for $\lambda_k = 0$. In order to be more explicit we evaluate (5.5) at $\lambda \neq 0$ for the constant cutoff function $R^{(0)}(z) = 1$. Though it does not vanish for $z \to \infty$, it yields at least qualitatively correct results [5, 6] as long as it does not introduce UV divergences into the integral under consideration. For $\Phi_1^2$ and $\Phi_1^2$ this is not the case and one finds

$$
\Phi_1^2(w) = \Phi_1^2(w) = (1 + w)^{-1}
$$

(5.8)

so that

$$
B_1^{(0)}(\lambda_k) = -2(1 - 2\lambda_k)^{-1} - \frac{32}{3}
$$

(5.9)

$$
B_2^{(0)}(\lambda_k) = (1 - 2\lambda_k)^{-1}
$$
As a consequence, we obtain the following answer for the anomalous dimension:

\[ \eta^{(0)}_N = -\frac{38}{3} g_k \frac{1 - \frac{32}{19} \lambda_k}{1 - g_k - 2\lambda_k} \quad (5.10) \]

Eq. (5.10) improves on earlier results in refs. [24, 25, 26]. It takes into account partially resummed higher loop effects (higher powers of \( g_k \)) and it includes the effect of the running cosmological constant.

One of the interesting features of Einstein–Hilbert gravity in \( 2 + \varepsilon \) dimensions is that the evolution of Newton’s constant is governed by a fixed point \( g_* \) at which the \( \beta \)-function (5.3) vanishes. To lowest order in \( \varepsilon \) it is given by

\[ g_* = -\varepsilon B_1^{(0)}(\lambda_k)^{-1} \quad (5.11) \]

The \( \lambda \)-dependence of \( g_* \) is non-universal. For \( R^{(0)} = 1 \) we obtain

\[ g_* = \frac{3}{38} \varepsilon \frac{1 - 2\lambda_k}{1 - \frac{32}{19} \lambda_k} \quad (5.12) \]

Eq. (5.12) is reliable for \( \lambda_k \ll 1 \). In this regime the fixed point \( g_* \) is UV stable if \( \varepsilon > 0 \) and it is IR stable for \( \varepsilon < 0 \). For \( \varepsilon > 0 \) and \( \lambda_k \equiv 0 \) this fixed point was discussed by Weinberg [25] in the context of the asymptotic safety scenario for quantum gravity. Our result for the dependence of \( g_k \) on the cosmological constant can only be obtained in a framework with a proper infrared regularization because we are investigating the influence of the relevant dimension–two operator on a marginal coupling. (In a sense, the rôle played by the running cosmological constant is similar to the quadratic mass renormalization in four dimensional scalar theories.) For \( \varepsilon > 0 \) the theory is asymptotically free. Near the fixed point the dimensionful Newton constant \( G_k = g_*/k^\varepsilon \) vanishes for \( k \to \infty \).

The evolution of \( \lambda_k \) itself is governed by eq. (4.43). For \( g_k \approx g_* \) where \( g_k \) and \( \eta_N \) are of order \( \varepsilon \), one finds that also the \( \beta \)-function of \( \lambda \) has a zero of order \( \varepsilon \):

\[ \lambda_* = -\frac{3}{38} \Phi_1^{(0)}(0) \varepsilon \quad (5.13) \]

This fixed point of the \( \lambda \)-evolution is UV stable for either sign of \( \varepsilon \). We conclude that to first order in \( \varepsilon \) and for \( \varepsilon > 0 \) the combined \( (\lambda, g) \)-system has an UV stable fixed point given by (5.13) together with \( g_* = (3/38)\varepsilon \).
5.2 Four dimensions

In $d = 4$ dimensions, the running of Newton’s constant is governed by the following functions of the cosmological constant:

\[ B_1(\lambda) = -\frac{1}{3\pi} \left[ 18\Phi_2^2(-2\lambda) - 5\Phi_1(2\lambda) + 6\Phi_2^2(0) + 4\Phi_1^2(0) \right] \quad (5.14) \]

\[ B_2(\lambda) = \frac{1}{6\pi} \left[ 18\Phi_2^2(-2\lambda) - 5\Phi_1(2\lambda) \right] \quad (5.15) \]

The dimensionful quantity $G_k$ evolves according to

\[ \partial_t G_k = \eta_N G_k \quad (5.16) \]

with the anomalous dimension given by (4.41). In order to get a feeling for the behavior of $G_k$, let us restrict our attention to the lowest order in $g_k$ which amounts to keeping only the first nontrivial correction of the expansion in $\bar{G}k^2$.

Then $\eta_N = B_1(\lambda_k)g_k + \ldots$, or with $g_k = k^2G_k = k^2\bar{G} + O(\bar{G}^2)$,

\[ \eta_N = B_1(\lambda_k)\bar{G}k^2 + O(\bar{G}^2) \quad (5.17) \]

First we consider the case where the cosmological constant is much smaller than $k^2$. Then we may approximate $\lambda_k \approx 0$ in (5.17), and (5.16) has the solution

\[ G_k = G_0 \left[ 1 - \omega \bar{G}k^2 + O(\bar{G}^2k^4) \right] \quad (5.18) \]

Here

\[ \omega \equiv -\frac{1}{2} B_1(0) = \frac{1}{6\pi} \left[ 24\Phi_2^2(0) - \Phi_1^2(0) \right] \quad (5.19) \]

is a pure number, which depends on the function $R^{(0)}$, however. For the exponential cutoff (2.14) we have $\Phi_1^2(0) = \pi^2/6$ and $\Phi_2^2(0) = 1$, so that

\[ \omega = \frac{4}{\pi} \left( 1 - \frac{\pi^2}{144} \right) > 0 \quad (5.20) \]

For different cutoff functions the numerical value of $\omega$ will be slightly different but it will still be positive. Therefore eq. (5.18) tells us that Newton’s constant decreases as $k^2$ increases; it is small in the UV and grows larger as we evolve it towards the infrared. The sign of this effect is the same as for the non–abelian gauge coupling in Yang–Mills theory and it is opposite to the one in QED. The main difference is that $G_k$ depends quadratically on $k$ while, to lowest order,
the gauge coupling in Yang–Mills theory runs only logarithmically. We see that gravity is “antiscreening” in the sense that at large distances Newton’s constant is larger than at small distances. This confirms the intuitive picture that the gravitational charge (mass) is not screened by quantum fluctuations but rather receives an additional positive contribution from the virtual particles surrounding it.

Let us consider a gravitational (thought) experiment which involves a typical length scale \( r \), the distance of two heavy test particles, for instance. If \( r \equiv k^{-1} \) acts as the effective IR cutoff scale, eq.(5.18) suggests the following form of a distance–dependent Newton’s constant (with factors of \( \hbar \) and \( c \) restored):

\[
G(r) = G(\infty) \left[ 1 - \omega \frac{\hbar}{r^2c^3} + O \left( \frac{1}{r^4} \right) \right] \tag{5.21}
\]

We expect that, to leading order in \( 1/r \), the quantum corrected static Newtonian potential of two test masses should be closely related to \( V(r) = -G(r)m_1 m_2/r \).

It is interesting to compare (5.21) to what is actually obtained by a diagrammatic calculation of the lowest order correction to the potential. Recently Donoghue [28] has pointed out that quantized Einstein gravity makes a well defined prediction for this quantity which is unaffected by the nonrenormalizability of the theory. One finds a result of the form

\[
V(r) = -G \frac{m_1 m_2}{r} \left[ 1 - \frac{G(m_1 + m_2)}{2c^2r} - \bar{\omega} \frac{\hbar}{r^2c^3} \right] \tag{5.22}
\]

The term proportional to \((m_1 + m_2)/r\) is a kinematic effect of classical general relativity; it is independent of \( \hbar \) and is not related to the \( \beta \)–function of \( G_k \) therefore. However, the last term in (5.22), proportional to \( G\hbar/r^2 \), has precisely the same structure as (5.21). The most recent calculation of \( \bar{\omega} \) was performed in ref.[29] with the result

\[
\bar{\omega} = \frac{118}{15\pi} > 0 \tag{5.23}
\]

This number has the same sign and is of the same order of magnitude as the value found originally in ref.[28], but there is no precise agreement yet. In ref.[30], \( \bar{\omega} \) was calculated using different methods [31, 32] and a negative value was found; this

---

5Recall that in QED the analogous substitution \( e^2/r \to e^2 (r^{-1})/r \) correctly reproduces the leading term of the Uehling potential if the one–loop formula for the running coupling \( e^2(\mu) \) is used [27].
would correspond to “screening” rather than “antiscreening”. Possible reasons for this discrepancy were discussed in ref. [29]. While the issue is not fully settled yet, it is believed that by correctly identifying and evaluating the set of relevant Feynman diagrams, quantum Einstein gravity gives rise to an unambiguous value for $\tilde{\omega}$. From our investigation of the renormalization group flow we expect this value to be positive.

One can use the full nonperturbative information contained in (4.41) in order to extend the domain of validity of our result towards larger values of $g_k$ or smaller distances $r$. This would involve a numerical solution of eq. (4.38) on which we shall not embark at this point.

In our approach we can study the influence of the cosmological constant on the running of $G_k$. It is an interesting question, for instance, whether a large $\lambda_k$ can destroy the antiscreening character of the gravitational interaction ($\eta_N < 0$). Let us look at (5.17) with $B_1(\lambda_k)$ given in (5.14). If there exists a regime with $\eta_N > 0$ (screening) then $B_1(\lambda)$ must be positive there. This can only happen if the term $5\Phi(-2\lambda_k)$ in the brackets on the RHS of (5.14) is larger than the sum of the other terms because the $\Phi$’s are always positive. However, $\Phi^p(w)$ decreases for increasing $w$ and finally vanishes for $w \to \infty$. Therefore a negative cosmological constant will not change the sign of $\eta_N$ since $B_1(\lambda_k) < 0$ for $\lambda_k \leq 0$.

For $\lambda_k > 0$, the $\Phi$’s in (5.14) are evaluated at negative arguments $w \equiv -2\lambda_k$. From (4.32) it is clear that $\Phi^p(w)$ blows up for $w \to -1$. (The function $z + R^{(0)}(z)$ assumes its minimum value 1 at $z = 0$ and increases monotonically for $z > 0$.) This signals that our approximation breaks down for $\lambda_k \approx 1/2$ or $\tilde{\lambda}_k \approx k^2/2$. For moderately large values of $\lambda_k$, $B_1(\lambda_k)$ is still negative. As $\lambda_k$ approaches 1/2 from below, only the first two terms on the RHS of (5.14) are important. It might be that $B_1$ turns negative then, but this would be in a regime where our truncation is not reliable any more, and the sign would even depend on $R^{(0)}$ in general.

At this point a general remark concerning the domain of validity of our truncation might be in order. In section 3 we showed that truncations of the form (3.11) with $\hat{\Gamma}_k = 0$ are consistent with the modified Ward identities provided $Y_k$ is small. For the Einstein–Hilbert truncation we can evaluate the traces in (3.9) and we can express $Y_k$ in terms of the functions $\Phi^p_n(w)$. It is clear, therefore, that $Y_k$ becomes large for $w \to -1$, and that our truncation cannot account for this regime.
The running of the (dimensionful) cosmological constant itself is governed by the equation
\[ \partial_t \bar{\lambda}_k = \eta_N \bar{\lambda}_k + \frac{1}{2\pi} k^4 G_k \left[ 10\Phi_2^1(-2\bar{\lambda}_k/k^2) - 8\Phi_2^1(0) - 5\eta_N \Phi_2^1(-2\bar{\lambda}_k/k^2) \right] \tag{5.24} \]
If we switch off the renormalization group improvement for a moment and set \( \eta_N = 0, \bar{\lambda}_k = 0 \) on the RHS of eq.\,(5.24), it has the solution
\[ \bar{\lambda}_k = \frac{1}{4\pi} \Phi_2^1(0) \tilde{G}(k^4 - \Lambda^4) + \bar{\lambda}_\Lambda \tag{5.25} \]
We observe the canonical scale dependence \( \bar{\lambda}_k \sim k^4 \) which one expects in any naive one–loop calculation: if \( \bar{\lambda}_k \) starts off positive at \( k = \Lambda \), its absolute value decreases when \( k \) is lowered until it reaches zero and then \( \bar{\lambda}_k \) becomes negative (for \( \Lambda \) large enough). It is obvious that any attempt to fine–tune \( \bar{\lambda}_\Lambda \) in such a way that \( \lim_{k \to 0} \bar{\lambda}_k = 0 \) cannot have a universal meaning because \( \Phi_2^1(0) \) depends on the form of the cutoff. The evolution equation (5.24) improves on the one–loop result in two respects: it includes the effect of the running \( G_k \), and via the “threshold function” \( \Phi_2^1 \) it describes the backreaction of the changing \( \bar{\lambda}_k \) on its \( \beta \)-function. In particular, for \( \bar{\lambda}_k < 0 \) and \( k^2 \ll |\bar{\lambda}_k| \) the relevant IR cutoff in the graviton propagator is \( |\bar{\lambda}_k| \) rather than \( k^2 \). Then the graviton modes do not contribute to the running of \( \bar{\lambda}_k \) any longer, and their decoupling is described by the function \( \Phi_2^1(w) \). If, on the other hand, the evolution starts with \( \bar{\lambda}_k > 0 \), the threshold functions make the coefficient of the \( k^4 \)-term in (5.24) even larger, and the running towards zero is faster than in (5.25). This effect is counteracted by the term \( \eta_N \bar{\lambda}_k \) which is negative for \( \eta_N < 0 \). It cannot prevent \( \bar{\lambda}_k \) from overshooting zero, however.

6 Conclusion

In this paper we proposed a general framework for the treatment of quantum gravity along the lines of the Wilsonian renormalization group. We introduced a scale–dependent effective action and we derived an exact renormalization group equation which describes its dependence on the built–in infrared cutoff. The effective action is invariant under general coordinate transformations; no symmetry violating terms are generated during the evolution. It satisfies a set of modified gravitational Ward identities which ensure that, in the limit of a vanishing cutoff,
the conventional Ward identities are recovered. By virtue of the
diffeomorphism–invariance of the effective action, fairly simple invariant truncations of the space
of actions are sufficient to describe the essential physics in a nonperturbative way.
The modified Ward identities provide a check for the quality of the truncations.
The evolution equation can be used both for the quantization of fundamental the-
ories ($\Lambda \to \infty$) and for the evolution of effective theories ($\Lambda$ finite). It is defined in
terms of manifestly finite, ultraviolet convergent functional traces. The evolution
equation by itself is meaningful even if the action is not positive definite. In this
case the original euclidean functional integral formulation might be problematic,
and the precise relation between the two approaches is not entirely clear yet.

As a first application, we have tested our method within a simple truncation
which retains only the invariants $\int \sqrt{g} R$ and $\int \sqrt{g}$. Nevertheless, the resulting
evolution equations for Newton’s constant and the cosmological constant contain
nonperturbative information. In $2 + \varepsilon$ dimensions we found corrections to the $\beta$–
function for $G_k$ and we determined its dependence on the cosmological constant.
In 4 dimensions we saw that the $\beta$–function for $G_k$ depends on $k$ quadratically,
and that Newton’s constant increases at large distances. Within its restricted
domain of validity, this result confirms earlier speculations by Polyakov \[33\] on a
possible gravitational antiscreening.

It would be interesting to allow for a more general truncation and to include
more complicated invariants in the ansatz for $\Gamma_k$. Not only higher powers of
the curvature should be kept but also, and perhaps more importantly, nonlocal
terms must be included (similar to the 2D induced gravity action $\int R D^{-2} R$, for
instance). This would lead to a better understanding of quantum gravity in the
extreme infrared, and might help to clarify certain issues in quantum cosmology.
For instance, it has been proposed that quantum gravitational effects at large
distances should be important both in the context of the dark matter problem
\[34\] and the cosmological constant problem \[14, 33\]. In fact, it is quite clear that
the nature of the IR divergences, and hence of the renormalization group flow
for $k \to 0$, is quite different depending on whether $\lambda$ is zero or not \[13\]. In a
perturbative expansion, one of the traces on the RHS of the evolution equation
consists of graviton loops attached to external graviton lines. The most singular
(for $k \to 0$) diagrams are those which involve the vertices obtained by expanding
$\lambda \int \sqrt{g}$, because they do not contain any momentum factors. Hence for $\lambda \neq 0$ the
renormalization effects should be much stronger than for $\lambda = 0$, and this could eventually drive the cosmological constant to zero. We hope to come back to this point elsewhere.

Acknowledgement: I would like to thank C.Wetterich for many helpful discussions.
