Quasinormal modes of scalar, electromagnetic, and gravitational fields in the extreme Schwarzschild-de Sitter background are known to be expressed in analytic form as eigenvalues of the Pöschl-Teller wavelike equation. We show that perturbations of fermionic fields (given by Dirac and Rarita-Schwinger equations) do not lead to the Pöschl-Teller effective potential. Nevertheless, using the Frobenius method we find quasinormal modes analytically in this case as well. We write down the analytical formula for quasinormal frequencies of the near-extreme Schwarzschild-de Sitter black holes, which is valid for both bosonic and fermionic fields. We further extend the analysis to the case of charged rotating black holes and find a general analytical formula for quasinormal modes of the fields of various spin for the near extreme Kerr-Newman-de Sitter spacetime.

I. INTRODUCTION

Quasinormal modes are proper oscillation frequencies of gravitational or matter fields around black holes which depend only upon the black hole parameters and not on the way of perturbation of the system [1, 2]. One of the earliest and apparently the most elegant and simple calculation of quasinormal modes for Schwarzschild black holes was performed by Bahram Mashhoon via using the approximation of the exactly solvable eigenvalue problem given by the Pöschl-Teller wavelike equation. Later this approach was extended to the case of Reissner-Nordström and slowly rotating Kerr black holes [3]. The accuracy of the method, however, was insufficient, because it depends on how well the effective potential of the black hole fits the Pöschl-Teller potential.

Even though the study of quasinormal modes was concentrated around asymptotically flat solutions, the case of asymptotically de Sitter black holes has also been considered in a great number of papers [6–22], especially recently, in the context of Strong Cosmic Censorship [23–25]. Mostly, calculations of quasinormal modes for four-dimensional black holes are done with the help of numerical or semianalytical methods, because the exact solution of the wavelike equation cannot be found as a rule. Nevertheless, there is one exception: the Schwarzschild-de Sitter black hole, when the cosmological horizon approaches the event horizon. In this regime of the near-extreme Schwarzschild-de Sitter spacetime the wavelike equation approaches the Pöschl-Teller one and, therefore, the analytical formula for quasinormal modes of scalar electromagnetic and gravitational fields can be deduced [26]. Later this formula for bosonic fields was extended to the case of higher-dimensional Reissner-Nordström-de Sitter black holes [27]. More general forms of the Pöschl-Teller-like potentials have been recently considered in [28].

Although from the point of view of current astrophysical observations we are able to detect only quasinormal modes of the gravitational field, there is considerable interest in perturbations of fundamental fields of other spin as well. A realistic black hole is not an isolated object, but it exists in the astrophysical environment and is accompanied by radiation phenomena of fields of all sorts. The decay of fermionic fields have also been extensively studied in the literature [22, 23], because the Dirac field can describe neutrinos, while the Rarita-Schwinger field corresponds to gravitinos [44, 45]. After all, complete study of decay of all the fundamental fields allows one to understand the role of the spin field parameter in the processes of radiation.

In the present work we concentrate on the limit in which analytical expressions for quasinormal modes can be obtained. We will show here that perturbation equations for fermions do not reduce to the Pöschl-Teller wavelike equation, unlike the case of boson fields. Nevertheless, using the continued fractions we will obtain the analytical formula for quasinormal modes of the spin 1/2 (Dirac) and 3/2 (Rarita-Schwinger) fields in the regime of the near-extreme Schwarzschild-de Sitter black hole. We will also generalize this analytical treatment to the case of perturbations of scalar, electromagnetic, gravitational, Dirac and Rarita-Schwinger fields in the Kerr-Newman-de Sitter spacetime, allowing, unlike [6], for the rotation and electric charge.

The paper is organized as follows. Section II is devoted to a description of the Schwarzschild-de Sitter geometry in the near extreme limit. Section III deals with per-
perturbation equations in the near extreme regime. In Section V we deduce an analytical formula for quasinormal modes of half-integer spin in the Schwarzschild-de Sitter spacetime, while in Section VI the analytical formula for quasinormal modes of spin 0, 1, 1/2, 1, 3/2, 2 fields is deduced for the near extreme Kerr-Newman-de Sitter black hole. Finally, in Section VII we summarize the obtained results and discuss a number of open questions.

II. SCHWARZSCHILD-DE SITTER GEOMETRY IN THE NEAR EXTREME LIMIT

The line element of the Schwarzschild-de Sitter black hole can be written in the following form:

\[ ds^2 = -f(r)dt^2 + \frac{dr^2}{f(r)} + r^2(d\theta^2 + \sin^2 \theta d\phi^2), \]

where

\[ f(r) = 1 - \frac{2M}{r} - \frac{\Lambda r^2}{3}. \]

Here \( M > 0 \) is the black-hole mass and \( \Lambda > 0 \) is the cosmological constant.

The function \( f(r) \) has two positive roots, the event horizon \( r_e \) and the cosmological horizon \( r_c \), and can be expressed in the following form:

\[ f(r) = \frac{\Lambda}{3r}(r_e - r)(r - r_e)(r + r_e + r_c). \]

By comparing (3) and (2) one can express \( M \) and \( \Lambda \) in terms of \( r_e \) and \( r_c \) as follows:

\[ M = \frac{r_e r_c (r_c + r_e)}{2(r_c^2 + r_c r_e + r_e^2)}, \quad \Lambda = \frac{3}{r_c^2 + r_c r_e + r_e^2}. \]

In this paper we consider the near-extreme Schwarzschild-de Sitter black hole, i.e., the regime in which \( r_c - r_e \ll r_e \).

In this case it is convenient to use the value of the surface gravity \( \kappa_e \) as a small parameter,

\[ \kappa_e \equiv \frac{f'(r_e)}{2} = \frac{\Lambda (r_e - r_e)(2r_e + r_c)}{6r_e} = \frac{(r_e - r_e)}{2r_e^2} + \mathcal{O}(r_e - r_e^2). \]

We notice that

\[ M = \frac{r_e}{3} + \mathcal{O}(\kappa_e), \quad \Lambda = \frac{1}{r_e^2} + \mathcal{O}(\kappa_e), \]

and the metric function \( f(r) \) takes the following form:

\[ f(r) = \frac{(r_e - r)(r - r_e)}{r_e^2} + \mathcal{O}(\kappa_e^3). \]

The tortoise coordinate takes the following simple form:

\[ r_* = \int \frac{dr}{f(r)} = \frac{1}{2\kappa_e} \left( \ln \left( \frac{r - r_c}{r_e - r} \right) + \mathcal{O}(\kappa_e) \right). \]

Therefore, for the near-extreme Schwarzschild-de Sitter black hole one can find a closed form for \( r \) in terms of \( r_* \),

\[ r = r_e + r_c e^{2\kappa_e r_*}/(1 + e^{2\kappa_e r_*}) + \mathcal{O}(\kappa_e). \]

III. LINEAR PERTURBATIONS IN THE NEAR-EXTREME LIMIT

For static and spherically symmetric spacetime we can use the stationary ansatz and expansion into spherical harmonics for massless scalar \( (s = 0) \), Dirac \( (s = \pm 1/2) \), and electromagnetic \( (s = 1) \) fields, as well as for linear gravitational perturbations \( (s = 2) \) of odd and even parities,

\[ \varphi, \Phi, A_\mu, \delta g_{\mu\nu} \propto e^{-i\omega t} S(\theta, \phi) \Psi(r). \]

Then, the master equation for the radial part can be reduced to the wavelike form,

\[ \left( \frac{d^2}{dr^2} + \omega^2 - V_e(r) \right) \Psi = 0, \]

with the effective potentials (see, e.g., [2, 48, 49] and references therein)

\[ V_0 = f(r) \left( \frac{\ell(\ell + 1)}{r^2} + \frac{f'(r)}{r} \right), \]

\[ V_1 = f(r) \frac{\ell(\ell + 1)}{r^2}, \]

\[ V_2^{(s)} = f(r) \left( \frac{\ell(\ell + 1)}{r^2} - \frac{6M}{r^3} \right), \]

\[ V_2^{(r)} = f(r) \left( \frac{\ell(\ell + 1)}{r^2} - \frac{24M^2(\Lambda r^2 - 3M/r)}{(6M + (\ell - 1)(\ell + 2)r^2)^2} \right) \]

\[ \left( \ell - 1 \right) (\ell + 2) + \frac{3M}{r} \right) \right), \]

where the multipole number takes (half-)integer values, \( \ell = |s|, |s| + 1, |s| + 2, \ldots \). While the deduction of the effective potentials for perturbations of the boson fields is well known in the literature (see for example [1, 2, 44] and references therein), the case of fermion fields is less known. Therefore, for completeness, we briefly review this deduction in the appendices.

Substituting (7) and (8) into (12), (13), and (14), and taking into account (10), we find that the potentials for
\( s = 0, 1, 2 \) approach the Pöschl-Teller one,
\[ V_s(r_s) = \kappa_c^2 \frac{(\ell + s)(\ell + 1 - s)}{\cosh^2(\kappa_c r_s)} + \mathcal{O}(\kappa_c)^3, \tag{16} \]
for which the quasinormal spectrum is known. In this way it was shown that for the fields of the integer spin we have \[^{[20]}\]
\[ \omega = \pm i \sqrt{\left(\ell + \frac{1}{2}\right)^2 + \sinh^2(\kappa_c r_s)} + \mathcal{O}(\kappa_c)^3. \tag{17} \]
However, for the half-integer spin, the effective potential is not the Pöschl-Teller like when \( \kappa_c \to 0 \). In particular, by substituting \[^{[7]],[8],\text{ and } [10]^{[15]}\] into \[^{[15]}\], one can find that the effective potential for the massless Dirac field takes the following form:\[^{[4]}\]
\[ V_{\pm 1/2}(r_s) = \kappa_c^2 \left(\ell + \frac{1}{2}\right) \frac{\ell + \frac{1}{2} \pm \sinh(\kappa_c r_s)}{\cosh^2(\kappa_c r_s)} + \mathcal{O}(\kappa_c)^3. \tag{18} \]
Similarly, the effective potential for the Rarita–Schwinger field is reduced to the non-Pöschl-Teller one in the near-extreme limit of the Schwarzschild-de Sitter black hole (see Appendix \[^{[A]}\]).

**IV. QUASINORMAL SPECTRUM OF THE HALF-INTEGER SPIN FIELDS**

Using the Newman-Penrose formalism it is possible to separate perturbation equations for massless fields of any spin in the background of the Kerr-Newman-de Sitter geometry \[^{[19]}\]. After some algebra, the perturbation equations can be reduced to the master equation for the radial part of the conformally coupled scalar \((s = 0)\), massless Dirac \((s = \pm 1/2)\), Maxwell \((s = \pm 1)\), Rarita–Schwinger field \((s = \pm 3/2)\), and linear gravitational perturbations \((s = \pm 2)\) of the Schwarzschild-de Sitter black holes can be written in the following form \[^{[6]}\] (see Appendix \[^{[B]}\]):
\[
\left\{ \begin{array}{l}
\left( \frac{d}{dr} \frac{r^2}{f(r)} \right)^{1-s} - \frac{2 f(r) - r f'(r)}{r} \right. \\
\left. \frac{d}{dr} \frac{(2 s + 1)(2 s + 1) \Delta f(r)}{r^2} + \frac{f(r)(\ell - s)(\ell + 1 + s)}{r^2} \right) R(r) = 0.
\end{array} \right. \tag{19}
\]

\[^{1}\] We note that, when the cosmological horizon approaches the event horizon, one cannot consider \( \sinh(\kappa_c r_s) = \mathcal{O}(\kappa_c) \) since \( r_s \) is not a constant: Whatever small \( \kappa_c \) is, the value of the hyperbolic sine goes from \(-\infty \) to \( \infty \) between the horizons. For the same reason one cannot take \( \cosh(\kappa_c r_s) = \mathcal{O}(1) \).

Here \( \ell = |s|, |s| + 1, |s| + 2, \ldots \) is the (half-)integer multipole number and \( \omega \) is the frequency.

Following \[^{[7]}\], we represent solutions to \[^{[19]}\] using the Frobenius expansion,
\[ R(r) = (1 - \frac{r_c}{r})^{-s-i\omega/\kappa_c} \mathcal{E}(r) \sum_{k=0}^{\infty} b_k \left( \frac{1 - r_c/r}{1 - r_c/r_c} \right)^k. \tag{20} \]
The coefficients \( b_k \) satisfy the three-term recurrence relation,
\[ c_{0,1}(\omega)b_1 + c_{1,1}(\omega)b_0 = 0, \tag{21} \]
\[ c_{0,n}(\omega)b_n + c_{1,n}(\omega)b_{n-1} + c_{2,n}(\omega)b_{n-2} = 0, \tag{22} \]
with
\[ c_{0,n}(\omega) = \nu \rho_c (r_c - r_e)(r_c + 2r_c) \left\{ 2i\omega \nu_c (r_c^2 + r_c r_e + r_e^2) \right. \\
\left. - (r_c - r_e)(r_c + 2r_e)(n - s) \right\} = \mathcal{O}(\kappa_c)^2,
\]
\[ c_{1,n}(\omega) = \nu \rho_c (r_c - r_e)(r_c + 2r_c) \left\{ (1 - s^2)r_c (r_c - r_e)(r_c + 2r_c)(r_e^2 - r_e^2) \\
+ (2r_c^2 + 2r_c r_e - r_e^2) \left( 2i \omega \nu_c (r_c^2 + r_c r_e + r_e^2) \right)^2 \\
+ 2ii\omega \nu_c (2n - 1)(r_c^2 - r_e^2)(r_e + 2r_e) \\
- n(n - 1)(r_c - r_e)^2 (r_e + 2r_c) \right\} = 108r_c^3 \left\{ (\ell + 1)(n(n - 1) + \frac{2}{3}(1 - s^2)) \\
- 2i\omega \nu_c (2n - 1) - \omega \right\} = \mathcal{O}(\kappa_c)^3,
\]
\[ c_{2,n}(\omega) = -r_c^2 (r_c^2 - r_e^2)(r_c^2 + r_c r_e + r_e^2) \times \\
\times \left( 2i \omega - \frac{(n + s - 1)(r_c - r_e)(r_c + 2r_c)}{r_c(r_c^2 + r_c r_e + r_e^2)} \right) \times \\
\times \left( 2i \omega - \frac{(n - 1)(r_c - r_e)(r_c + 2r_e)}{r_e(r_c^2 + r_c r_e + r_e^2)} \right) = \mathcal{O}(\kappa_c)^3,
\]
where we took into account that \( \omega = \mathcal{O}(\kappa_c) \).

One can express \( b_1 \) using either \[^{[21]}\) or \[^{[22]}\) via the following relation:
\[ \frac{b_1}{b_0} = \frac{c_{1,1}(\omega)}{c_{0,1}(\omega)} = \frac{c_{2,2}(\omega)}{c_{1,2}(\omega)} = \frac{c_{0,2}(\omega) c_{2,3}(\omega)}{c_{1,3}(\omega)} \ldots \ldots \tag{23} \]
Equation \[^{[23]}\) with the infinite continued fraction is satisfied if and only if the Frobenius series \[^{[20]}\) converges. By inverting the continued fraction \( n \) times, we obtain the following equivalent equation \[^{[4]],[51]}\):
\[ c_{1,n+1}(\omega) = \frac{c_{2,n}(\omega) c_{0,n+1}(\omega) \ldots \ldots c_{2,n}(\omega) c_{0,n+1}(\omega)}{c_{1,n+1}(\omega)} = \frac{c_{2,n+2}(\omega) c_{0,n+2}(\omega) c_{2,n+3}(\omega)}{c_{1,n+2}(\omega)} \ldots \ldots \tag{24} \]
\[ = \frac{c_{0,n+1}(\omega) c_{2,n+2}(\omega) c_{0,n+2}(\omega) c_{2,n+3}(\omega)}{c_{1,n+2}(\omega)} = \frac{c_{0,n+3}(\omega) c_{2,n+4}(\omega)}{c_{1,n+3}(\omega)} \ldots \ldots \]
TABLE I. The fundamental quasinormal mode of the Dirac field, \(s = 1/2, \ell = 3/2\), obtained by the WKB method with Padé approximants, \(P_{5/4}\). The corresponding value, given by our analytical formula, is \(2 - 0.5i\).

| \((r_c - r_e)/r_e\) | \(\omega/\kappa_c\) |
|---------------------|------------------|
| 0.000900            | 1.999401 − 0.499853i |
| 0.000265            | 1.999823 − 0.499958i |
| 0.000171            | 1.999886 − 0.499974i |
| 0.000152            | 1.999899 − 0.499977i |
| 0.000142            | 1.999906 − 0.499979i |

Notice that formula (24) coincides with (17) for \(K = 1\) and \(s \neq 0\). For \(s = 0\) it gives us the quasinormal spectrum of the conformally coupled scalar field, while (17) was derived for the minimally coupled scalar field.

The simplification of Eq. (24) occurs because the coefficients \(c_{2,n}(\omega)\) of the near-extreme limit are negligible compared to \(c_{0,n}(\omega)\) and \(c_{1,n}(\omega)\). As a result, Eq. (24) becomes the two-terms recurrence relation and Eq. (25) implies that the infinite series in (20) is reduced to a finite sum, when \(\omega\) is a quasinormal frequency. The Frobenius series for the Kerr-de Sitter black-hole perturbations, proposed in [3], leads to the same simplification. Therefore, one can easily obtain a generalization of (20) for rotating black holes (see Sec. V). It is interesting to note that the expansion in terms of the hypergeometric functions [5] is not simplified in this case, leading to a three-terms relation when the event horizon approaches the de Sitter one.

Our analytical formula can be checked with the higher-order WKB (Wentzel–Kramers–Brillouin) formula of Will and Schutz [52], which was extended to higher orders in [53], [54] and made even more accurate by the usage of the Padé approximants in [55], [56]. The higher-order WKB formula reads [57]

\[
\omega^2 = V_0 + A_2(K^2) + A_4(K^2) + A_6(K^2) + \ldots
\]

\[-iK\sqrt{-2V_2} (1 + A_3(K^2) + A_5(K^2) + A_7(K^2) + \ldots),
\]

where \(K\) takes half-integer values, \(K = n + \frac{1}{2}\). The corrections \(A_k(K^2)\) of order \(k\) to the eikonal formula are polynomials of \(K^2\) with rational coefficients and depend on the values of higher derivatives of the potential \(V(r)\) in its maximum. In order to increase accuracy of the WKB formula, we follow Matyjasek and Opala [53] and use Padé approximants. The Padé approximants \(P_{n/m}\) are defined in Eq. (21) of [57]. In Table I we show that the fundamental \((n = 0)\) quasinormal mode of the Dirac field \((s = 1/2)\) for \(\ell = 3/2\), obtained by the WKB method with Padé approximants, approaches the limit

\[
\frac{\omega}{\kappa_c} \to 2 - 0.5i,
\]

which coincides with the analytical result (26).

As a by-product, let us consider a more general equation

\[
\left(\frac{d^2}{dx^2} + \omega^2 - A^2 + A\alpha \sinh(ax) \cosh^2(ax)\right) \Psi(x) = 0,
\]

(28)

where \(\alpha\) and \(A\) are real nonzero parameters. Since (26) for \(s = 1/2\) gives us the quasinormal spectrum of the wave-like equation (11) with the effective potential (18), we conclude that

\[
\omega = \pm A - |\alpha| \left(n + \frac{1}{2}\right)i, \quad n = 0, 1, 2, 3, \ldots
\]

(29)

are quasinormal modes for the general wave equation (28). It is clear that the effective potential in (28) always has a negative gap for sufficiently large values of \(x\), either positive (for \(A < 0\)) or negative (for \(A > 0\)). Nevertheless, as can be seen from the above analytic formulas for quasinormal modes, there are no unstable (growing) modes in the spectrum.

V. QUASINORMAL MODES OF THE NEAR-EXTREME KERR(-NEWMAN)-DE SITTER BLACK HOLES

Here we extend our analysis to the case of the Kerr(-Newman)-de Sitter spacetime, describing a charged and rotating black hole. The line element for this case has the form:

\[
ds^2 = -\frac{\Delta_r(dt - a \sin^2 \theta d\phi)^2}{(1 + \Lambda a^2/3)(r^2 + a^2 \cos^2 \theta)} + \frac{\Delta_\theta \sin^2 \theta (adr - (r^2 + a^2) d\phi)^2}{(1 + \Lambda a^2/3)(r^2 + a^2 \cos^2 \theta)} + (r^2 + a^2 \cos^2 \theta) \left(\frac{dv^2}{\Delta_r} + \frac{d\theta^2}{\Delta_\theta}\right),
\]

(30)

where

\[
\Delta_r = (r^2 + a^2) \left(1 - \frac{\Lambda r^2}{3}\right) - 2Mr + Q^2
\]

(31)

\[
\Delta_\theta = \frac{\Lambda}{3} (r_c - r)(r_c - r_e)(r + r_c + r_e + r_i),
\]

\[
\Delta_\alpha = 1 + \frac{\Lambda a^2}{3} \cos^2 \theta.
\]

(32)
Here $a$ is the rotation parameter and $Q$ is the electric charge. The latter can be expressed in terms of the inner horizon $r_+$, for which $0 < r_+ < r_c$.

For the charged black hole the background electromagnetic field is given by the components of the one-form

$$A_\mu dx^\mu = -\frac{Qr}{s^2 + a^2 \cos^2 \theta} \cdot dt - a \sin^2 \theta d\phi.$$  

(33)

The surface gravity is given by the following relation:

$$\kappa_c \equiv \frac{2(a^2 + r_c^2)(2a^2 + r_c^2 + r_c^2 + r_c r_+ + r_c r_- + r_+ r_-)}{r_c (r_+ - r_-)} = \mathcal{O}(r_+ - r_-).$$  

(34)

For the uncharged black hole ($Q = 0$) the inner horizon can be expressed in terms of the rotation parameter,

$$r_+ = \frac{r_c + r_-}{2} \left( 1 + \frac{4a^2}{r_c r_+ - a^2} - \frac{4a^2}{(r_+ + r_-)^2} \right) = \frac{r_+^2 + a^2}{\sqrt{r_+^2 - a^2}} - r_c + \mathcal{O}(\kappa_c).$$  

(35)

Omitting the deduction of the perturbation equation, which can be found in Appendix [B], we proceed to the analysis of the wave-like equation. The corresponding recurrence-relation coefficients have been derived in [S].

Taking the limit $\kappa_c \to 0$, we obtain

$$\beta_r = \mathcal{O}(\kappa_c),$$  

(36)

where $\beta_r$ is given by (54) in [S]. Equation (36) can be solved analytically as follows:

$$\omega = m \Omega_c \pm \kappa_c \sqrt{C_1 \lambda + C_2 m^2 \Omega_c^2 r_c^2 + \frac{(2s - 1)(2s - C_3)}{C_4}}$$

$$- C_2 m \Omega_c r_c \kappa_c - i \left( n - \frac{1}{2} \right) \kappa_c + \mathcal{O}(\kappa_c)^2,$$  

(37)

where $\Omega_c \equiv \frac{a}{a^2 + r_c^2}$ is the angular velocity at the event horizon, $m = -\ell, -\ell + 1, \ldots, \ell - 1, \ell$ is the azimuthal (half-)integer number, $n = 0, 1, 2, 3, \ldots$ is the overtone number, and $C_1, C_2, C_3,$ and $C_4$ are positive constants,

$$C_1 = \frac{a^2 + 3r_c^2 + 2r_c r_+ + r_+^2}{(r_c - r_+)(5r_c + r_+)},$$

$$C_2 = \frac{2a^2 + 3r_c^2 + 2r_c r_+ + r_+^2}{(r_c - r_+)(5r_c + r_+)},$$

$$C_3 = \frac{5r_c^2 + 2r_c r_+ + r_+^2}{(r_c + r_+)^2},$$

$$C_4 = \frac{(r_c - r_+)(5r_c + r_+)}{(r_c + r_+)^2}.$$  

(38)

When the charge $Q$ and rotation parameter $a$ go to zero, the general formula (37) is reduced to (26). Notice that the expression for $v_0$ in [S] has misprints and uses such dimensional units that $\Lambda = 3$. The accurate three-terms recurrence relation as well as derivation of the formula (37) are available in the Wolfram Mathematica® auxiliary file [58].

The separation constant $\lambda$ can be calculated for any $\omega$ (see Appendix [B]). In the near-extreme limit of the slowly rotating Kerr-de Sitter black hole ($Q = 0$), substituting (37) into (B11), we find

$$\lambda = (\ell + s)(\ell + 1 - s) \left( 1 - \frac{a^2}{3r_c^2} \right)$$

$$+ \frac{2a^2}{r_c^2} \left( \frac{(\ell + 1)^2 - m^2)((\ell + 1)^2 - s^2)^2}{(2\ell + 1)(\ell + 1)(2\ell + 3)} \right) - \frac{2m^2}{3}$$

$$- \frac{2m^2 s^2}{3(\ell + 1)} - \left( \frac{\ell^2 - m^2((\ell - s)^2)^2}{(2\ell - 1)(\ell + 1)^2} \right) + \mathcal{O}(a^4, \kappa_c).$$

Notice that the general expression (37) is valid for highly rotating black holes as well, although the separation constant $\lambda = \lambda(s, \ell, m, a, r_+, r_c = r_c)$ has not been found in analytic form in the that case.

VI. CONCLUSIONS

Quasinormal modes of the four-dimensional asymptotically flat or de Sitter black holes are found numerically as a rule. The exception is bosonic perturbations of the near extreme Schwarzschild-de Sitter black hole for which the wave-like equation takes the Pöschl-Teller form. In this case the quasinormal spectrum of the Schwarzschild-de Sitter black hole can be found analytically. Here we have shown that perturbations of fermionic (Dirac and Rarita-Schwinger) fields are not reduced to the Pöschl-Teller-like form. Nevertheless, using the Frobenius series, we have found the analytical formula for quasinormal modes of half-integer spin fields and, consequently, the general formula for spin 0, 1/2, 1, 3/2, 2 fields. We have also generalized this analytical formula to the case of Kerr-Newman-de Sitter black hole. Our analysis can be extended to the case of a higher dimensional gravity, as well as to black holes in four and higher-dimensional modified gravities.

1. Dirac field

The massless Dirac equation
\[ i\gamma^\mu \partial_\mu \psi = 0, \quad \psi \propto e^{-i\omega t}, \quad (A1) \]
in the Schwarzschild-de Sitter background simplifies to the coupled system of partial differential equations [59-61]
\[
-i\omega \psi_1 + \frac{d\psi_1}{dr_*} = W\psi_2,
\]
\[
-i\omega \psi_2 - \frac{d\psi_2}{dr_*} = -W\psi_1, \quad (A2)
\]
where \( \psi_1 \) and \( \psi_2 \) are the components of a two-dimensional spinor,
\[
W = (\ell + 1/2) \frac{\sqrt{f(r)}}{r}, \quad (A3)
\]
where \( \ell \) is a positive half-integer number, \( \ell = \frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \ldots \).

One can rewrite Eqs. (A2) as follows:
\[
\frac{dZ_+}{dr_*} + i\omega Z_+ = WZ_-, \quad (A4)
\]
\[
\frac{dZ_-}{dr_*} + i\omega Z_- = -WZ_+, \quad (A5)
\]
where
\[
Z_{\pm} = \psi_{1\pm} \psi_1. \quad (A6)
\]

From Eqs. (A3) one can obtain the wavelike equations for the functions \( Z_{\pm} \)
\[
\frac{d^2 Z_{\pm}}{dr_*^2} + \omega^2 Z_{\pm} = V_{\pm1/2}Z_{\pm}, \quad (A7)
\]
where the effective potentials \( V_{\pm1/2} \) are given by,
\[
V_{\pm1/2} = W^2 \pm \frac{dW}{dr_*}. \quad (A8)
\]
The latter relation leads immediately to Eq. (15).

2. Rarita-Schwinger field

It was shown in [62] that equations for the components of the Rarita-Schwinger field in the Schwarzschild-de Sitter background can be reduced to the form (A2) as well. However, in this case both the function \( W \) and the tortoise coordinate \( r_* \) depend on \( \omega \),
\[
dr_* = \frac{dr}{f(r)} \left[ 1 + \frac{f}{2\omega} \left( \frac{d}{dr} \frac{D}{D^2} \left( \frac{B^2}{B^2 - D^2} \right) \right) \right], \quad (A9)
\]
\[
W = \sqrt{D^2 - B^2} \left[ 1 + \frac{f}{2\omega} \left( \frac{d}{dr} \frac{D}{D^2} \left( \frac{B^2}{B^2 - D^2} \right) \right) \right]^{-1}, \quad (A10)
\]
with
\[
B = i(\ell + 1/2) \sqrt{r} \left( 1 + \frac{2M/r}{f(r) + \frac{1}{2}A^2 - (\ell + 1/2)^2} \right),
\]
\[
D = -i \sqrt{\frac{M^2}{3} - f(r) + \frac{1}{2}A^2 - (\ell + 1/2)^2}, \quad (A11)
\]
where the multipole number \( \ell = \frac{3}{2}, \frac{5}{2}, \frac{7}{2}, \ldots \).

Thus, the effective potential for the Rarita-Schwinger field does not depend on \( \omega \) only in the Schwarzschild limit [63].

It is interesting to note that in the limit of the near-extreme Schwarzschild-de Sitter black hole Eq. (A8) takes the form,
\[
dr_* = \frac{dr}{f(r)} + O(\kappa_\ast), \quad (A12)
\]
\[
W = \sqrt{f(r)}/r \cdot \sqrt{\ell^2 - \frac{13}{12}} + O(\kappa_\ast^2), \quad (A13)
\]
and the effective potential approaches
\[
V_{\pm3/2}(r_*) = \kappa_\ast^2 \sqrt{\ell^2 - \frac{13}{12} + \frac{13}{12} \pm \sinh(\kappa_\ast r_*)} + O(\kappa_\ast^3). \quad (A14)
\]

The potential (A14) has the same form as the effective potential for the Dirac field (28). Therefore, from Eq. (29) one can obtain the correct spectrum given by (30) for \( s = \pm \frac{3}{2} \).

Appendix B: Master equations for the Kerr-Newman-de Sitter black-hole perturbations

We use the Newman-Penrose formalism [49] in order to separate the perturbation equations in the background of the Kerr-Newman-de Sitter black hole [59].

Following [6], we introduce the following vectors as the null tetrad:
\[
l^\mu = 1 + \alpha \left( r^2 + a^2, \frac{\Delta_r}{1 + \alpha}, 0, a \right), \quad \alpha \equiv \frac{\Lambda a^2}{3}, \quad (B1)
\]
\[
n^\mu = 1 + \alpha \left( 2(r^2 + a^2 \cos^2 \theta), \frac{\Delta_r}{1 + \alpha}, 0, a \right), \quad (B2)
\]
\[
m^\mu = 1 + \alpha \left( \frac{r + ia \cos \theta}{\sqrt{2 \Delta_r}} \left( \frac{1}{1 + \alpha}, \Delta_{\theta}, 0, \frac{i}{\sin \theta} \right) \right), \quad (B3)
\]
\[
r^\mu = 1 + \alpha \left( \frac{r - ia \cos \theta}{\sqrt{2 \Delta_r}} \left( -ia \sin \theta, 0, \frac{\Delta_{\theta}}{1 + \alpha}, -i \sin \theta \right) \right), \quad (B4)
\]
and assume the following ansatz for all the scalar quantities:
\[
\Phi_\ast(t, r, \theta, \phi) \propto e^{-i\omega t + im\phi} S_\ast(\theta) R_\ast(r). \quad (B5)
\]
It is convenient to use the tetrad components of the derivative and the electromagnetic field as follows:

\[
\begin{align*}
 l^\mu \partial_\mu &= D_0, \\
 n^\mu \partial_\mu &= -\frac{\Delta_r}{2(r^2 + a^2 \cos^2 \theta)} D^\mu_0, \\
 m^\mu \partial_\mu &= \frac{\sqrt{\Delta_\theta}}{\sqrt{2(r + ia \cos \theta)}} L_0, \\
 \bar{m}^\mu \partial_\mu &= \frac{\sqrt{\Delta_\theta}}{\sqrt{2(r - ia \cos \theta)}} L_0, \\
 l^\mu A_\mu &= -\frac{Qr}{\Delta_r}, \\
 n^\mu A_\mu &= -\frac{Qr}{2(r^2 + a^2 \cos^2 \theta)}, \\
 m^\mu A_\mu &= \bar{m}^\mu A_\mu = 0,
\end{align*}
\]  

(B3)

where we introduced

\[
\begin{align*}
 D_n &= \partial_\rho - \frac{i(1 + \alpha)K}{\Delta_r} + n \partial_r \Delta_r, \\
 D^\dagger_n &= \partial_\rho + \frac{i(1 + \alpha)K}{\Delta_r} + n \partial_r \Delta_r, \\
 D_\theta &= \partial_\theta + \frac{(1 + \alpha) H}{\Delta_\theta} + \frac{\partial_\theta(\sqrt{\Delta_\theta \sin \theta})}{\sqrt{\Delta_\theta \sin \theta}}, \\
 D^\dagger_\theta &= \partial_\theta - \frac{(1 + \alpha) H}{\Delta_\theta} + \frac{\partial_\theta(\sqrt{\Delta_\theta \sin \theta})}{\sqrt{\Delta_\theta \sin \theta}}, \\
 H &= -a \omega \sin \theta + \frac{m}{\sin \theta}.
\end{align*}
\]

The gravitational-led perturbations of the Kerr-Newman-de Sitter black-hole can be expressed in terms of the Weyl tensor \( C_{\mu \nu \lambda \sigma} \),

\[
\begin{align*}
 \Phi_{+2}(t, r, \theta, \phi) &= C_{\mu \nu \lambda \sigma} l^\mu n^\nu m^\lambda \bar{m}^\sigma, \\
 \Phi_{-2}(t, r, \theta, \phi) &= \frac{C_{\mu \nu \lambda \sigma} n^\mu \bar{m}^\nu m^\lambda \bar{m}^\sigma}{(r^2 + a^2 \cos^2 \theta)^2},
\end{align*}
\]

(B6)

and the quantities

\[
\begin{align*}
 \Phi_{+1}(t, r, \theta, \phi) &= F_{\mu \nu} l^\mu n^\nu, \\
 \Phi_{-1}(t, r, \theta, \phi) &= \frac{F_{\mu \nu} n^\mu \bar{m}^\nu}{r^2 + a^2 \cos^2 \theta},
\end{align*}
\]

(B7)

correspond to the perturbations due to the electromagnetic field, \( F_{\mu \nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu \).

The conformally coupled test scalar field obeys

\[
\frac{1}{\sqrt{-g}} \partial_\mu \sqrt{-g} g^{\mu \nu} \partial_\nu \Phi_0 = \frac{R}{6} \Phi_0,
\]

(B8)

where \( R = 4\Lambda \) is the scalar curvature.

In [64] it was shown that the perturbation equations for:

- the test scalar field \( \Phi_0 \) obeying the Klein-Gordon equation (B8);
- the independent components of the massless Dirac field, \( \Phi_{\pm 1/2} \);
- Maxwell field wave function \( \Phi_{\pm 1} \) defined in (B7);
- the independent components of the Rarita-Schwinger field, \( \Phi_{\pm 3/2} \);
- gravitational perturbations \( \Phi_{\pm 2} \) defined in (B6);

allow for separation of the angular variables and, in the end, satisfy the Teukolsky equations [61].

After introducing the new variable, \( x \equiv \cos \theta \), the coefficients of the angular Teukolsky equation (B9) become rational functions of \( x \) with five regular singularities, one of which, corresponding to \( x = \infty \), can be factored out. In this way, equation (B9) is reduced to the Heun’s equation, and the separation constant \( \lambda \) can be computed for any given value of \( \omega \). In particular, for the slowly rotating black hole, one can obtain Eq. (4.18) of [6], which has the following cumbersome form:
\begin{align}
\lambda &= (\ell + 1 - s)(\ell + s) + \alpha \left[ -(\ell + 1 - s)(\ell + s) + 2m^2 + \frac{2m^2 s^2}{\ell (\ell + 1)} - \ell^2 H(\ell) + (\ell + 1)^2 H(\ell + 1) \right] \\
&\quad + \left\{ -2m \left( \frac{s^2}{\ell (\ell + 1)} \right) - 2m \alpha \left[ \frac{s^2}{\ell (\ell + 1)} - \frac{s^2}{(\ell - 1)(\ell + 1)} \right] H(\ell) + \left( \frac{1}{\ell (\ell + 2)} \right) H(\ell + 1) \right\} a_{\omega} \nonumber \\
&\quad + \left\{ H(\ell + 1) - H(\ell) + 2 \left[ (\ell + 1)^2 H(\ell) - \ell^2 H(\ell) \right] \right. \\
&\quad \left. - \ell H^2(\ell + (\ell + 1))^2 H(\ell + 1) - \frac{H(\ell + 1)}{\ell (\ell + 1)} + 6m^2 s^2 \left( \frac{H(\ell + 1)}{\ell^2 (\ell + 1)} - \frac{H(\ell)}{(\ell - 1)^2 (\ell + 1)^2} \right) \right\} a_{\omega}^2 + O(\alpha^2, a^3 \omega^3), \\
&\quad H(L) \equiv \frac{2(L^2 - m^2)(L^2 - s^2)^2}{(2L - 1)L^4(2L + 1)}.
\end{align}

Here \( \ell_i, \ell_{i+1}, \ell_{i+2}, \ldots \) is the multipole number, and we have \( \ell_i \equiv \min(|m|, |s|). \)

The radial Teukolsky equation \cite{11}.

\[
\Delta r \frac{d}{dr} \Delta r^{s+1} \frac{d}{dr} + \frac{1}{\Delta r} \left[ (1 + \alpha)^2 K^2 - i s (1 + \alpha) K \Delta r \right] \\
+ 4 i s (1 + \alpha) \omega r - \frac{2a}{3} (s + 1)(2s + 1)r^2 \\
+ 2s(1 - \alpha) - \lambda \right\} R = 0,
\]

has five regular singularities: \( r = r_c, r = r_e, r = r_i, r = r_0 = -(r_c + r_e + r_i), \) and \( r = \infty. \) In order to introduce the Frobenius expansion with the coefficients, satisfying the three-terms recurrence relation, we need to take into account behaviour of the solution in all the singular points. The appropriate expansion is obtained in \cite{5}.

\[
R_s(r) = \left( \frac{r - r_c}{r - r_0} \right)^{B_1} \left( \frac{r - r_i}{r - r_0} \right)^{B_2} \left( \frac{r_c - r}{r - r_0} \right)^{B_3} \\
\times (r - r_0)^{-1 - 2s} \sum_{k=0}^{\infty} b_k \left( \frac{r - r_c}{r_c - r_0} \right)^k.
\]

The exponents \( B_1, B_2, B_3 \) and the corresponding recurrence relation coefficients can be found in the ancillary Mathematica® notebook \cite{5a}.
