Abstract. Geological storage of carbon dioxide represents a viable solution to reduce the greenhouse gases in the atmosphere. Romania has initiatives to build a large-scale integrated CO\textsubscript{2} capture and storage demonstration project and find suitable on-shore and off-shore CO\textsubscript{2} storage locations. Numerical simulators are essential tools helping the design process. These simulators are required to be capable to represent the complex thermo-hydro-mechanical-chemical and biological phenomena accompanying the geological CO\textsubscript{2} storage such as, multi-phase flow, compositional effects due to dissolution of CO\textsubscript{2} into the brine, non-isothermal effects due to cold CO\textsubscript{2} injection, geomechanical effects, mineralization at the reservoir-scale. These processes can be simulated accurately and efficiently with DuMu\textsuperscript{x} (www.dumux.org), a free- and open-source simulator. This article presents and reviews briefly these mathematical and numerical models.

1 Introduction

Reduction of greenhouse gas emissions has been proposed by United Nations beginning with the 1997 Kyoto Protocol and the most recent Paris Agreement negotiated in 2015 Climate Change Conference. Among the technologies able to reduce the greenhouse gas emissions, carbon capture and storage (CCS) in geological formations represents most viable option for storage [1]–[4]. Generally, the geological CO\textsubscript{2} storage can be done in depleted oil/gas fields, coal seams, salt caverns, or in deep saline formations below 800 meters, which also have the highest estimated storage capacity of more than 1000 Gt [2]. The main criteria for selecting a long-term CO\textsubscript{2} storage site are the size (reservoir extent), porosity and permeability, i.e. large porosities ensure the volume for storage while a large permeability a good injectivity, depth below 800 m to guarantee the CO\textsubscript{2} is in supercritical form, and an overlying impervious cap rock (e.g., Tatomir et al. 2016). Current state of the art of CCS is at a stage where the transition from pilot to large-(industrial-) scale projects is required.

Another technology to reduce the greenhouse gas emissions is the Carbon Capture Utilization and Storage (CCUS). CCUS aims to increase the economic viability of the CO\textsubscript{2} storage by making use of the CO\textsubscript{2} and subsequently reducing the emissions to the atmosphere; for instance, increasing the oil/gas recovery by injecting CO\textsubscript{2}. Unlike CO\textsubscript{2} storage, the enhanced oil recovery (EOR) and enhanced gas recovery (EGR) using CO\textsubscript{2}, i.e., CO\textsubscript{2}-EOR, are already operating on a commercial scale [6]. CCUS technologies list CO\textsubscript{2}-EOR, CO\textsubscript{2}-EGR, CO\textsubscript{2}-enhanced coal bed methane production, CO\textsubscript{2}-enhanced shale gas production, CO\textsubscript{2}-enhanced geothermal systems, etc.

Global CCS pilot plants and initiatives are reviewed in [4], [7], [8].

The main objective of this article is to introduce mainly to the Romanian scientific community the open source numerical simulator DuMu\textsuperscript{x} [9] and review its applicability to geological storage of CO\textsubscript{2}. We do not present any modelling results of potential storage sites but refer the reader to the literature sources where such studies have already been conducted at field and regional scales.

1.1 CCS in Romania

Assessing the GCS in Romania has been conducted in a number of studies. [10] investigates the potential of Romanian Black Sea shelf for CO\textsubscript{2} storage, in particular the deep saline formations of the Histria Depression. The authors identify three potential locations in the Lower and Upper Cretaceous and Middle Eocene formations, composed mainly of sands and sandstones. The depths range from 1820 – 2850 m, with a permeability up to 200 mD and a porosity of up to 30%. Available well data provide a good representation of the layers in the three identified reservoirs.

[11] aims to identify suitable locations for a CCS Demo Project in the Oltenia Region in an area 50 km around Turceni Power Plant. The formation unit is called Getic Depression, a sedimentary basin at the contact between South Carpathians and the Moesian Platform. The large scale GETICA CCS Demo project aims to
The system of partial differential equations (1) is closed with the following equations:

\[ S_0 + S_n = 1, \]
\[ p_w - p_n = p_c, \]

where \( \alpha \) is the phase number, \( w \) is the wetting phase, \( n \) is the non-wetting phase, \( S_0 \) is the phase saturation, \( p_w \) is the phase pressure and \( p_n \) is the capillary pressure. If the solid matrix is allowed to deform the effective porosity \( \phi \) and intrinsic permeability \( K \) are determined as functions of the solid displacement.

The spatial discretization methods available for different models are the vertex-centered finite volume method, the standard Galerkin finite element method. The time discretization is a fully implicit Euler method. The models can be solved fully coupled or sequentially. By choosing a model with sequential coupling larger speed-up factors are usually obtained.

The practical modelling of flow and transport processes in porous media at reservoir-scale applications requires the definition of the properties, quantities and processes on a representative elementary volume (REV). Generally, all models implemented in DuMu\textsuperscript{x} are constructed on the assumption that a REV exists at the Darcy scale. Exceptions use for instance pore-network models to couple mass, momentum and energy at the interface between free flow and porous media flow.

For CO\textsubscript{2} storage in porous media the relevant processes can be described by the multiphase flow in porous media equations, the multiphase multicomponent balance equations, the non-isothermal multiphase flow and non-isothermal multi-phase multi-component equations, and by hydrogeomechanical equations when accounting for the deformations of the porous media. These processes can be simulated with the DuMu\textsuperscript{x} models given in Table 1. During the CO\textsubscript{2} injection period the most important processes can be modelled with the 2p2ni or 2p2cni models. After several hundreds of years when the temperature effects become negligible, the 2p2c model is computationally more efficient.

The mass balance equations for multi-phase flow in porous media can be formulated as:

\[
\frac{\partial (\phi_S \rho_S \rho)}{\partial t} - \nabla \cdot \left( \rho \frac{\mu}{\rho_a} \left( \nabla p_a - \rho_a g \right) \right) - q_a = 0 \tag{1}
\]

The physical chemical processes involved in GCS and described by the models (section 1.2) are highly coupled and non-linear. The fluid properties are functions of pressure, temperature, salinity, and composition.

DuMu\textsuperscript{x} [17] (www.dumux.org) stands for DUNE for Multi-{Phase, Component, Scale, Physics, …} and is mainly developed at the University of Stuttgart, Germany since 2007. It is a free and open-source simulator for multiphase flow, multicomponent transport in porous media. DuMu\textsuperscript{x} has been applied to a number of geological CO\textsubscript{2} storage scenarios [13]–[15], [18], [19]. DuMu\textsuperscript{x} is based on the Distributed and Unified Numerics Environment DUNE (www.dune-project.org).
\[
\sum_{a} \frac{\partial (\phi S_{a} \rho_{a} x_{a}^{N})}{\partial t} - \nabla \cdot \left( \rho_{a} x_{a}^{N} k_{r_{a}} K(\nabla p_{a} - \rho_{a} g) \right)
\]

The injected CO2 has a different temperature, usually lower, than the formation fluids. In this sense, the non-isothermal processes occurring during the CO2 injection can be represented with the energy balance equation, assuming local thermal equilibrium [20], [21]:

\[
\frac{\partial (\sum_{\alpha} \rho_{\alpha} x_{\alpha} S_{\alpha})}{\partial t} + \nabla \cdot \left( \rho_{\alpha} h_{\alpha} k_{r_{\alpha}} K(\nabla p_{\alpha} - \rho_{\alpha} g) \right) = 0
\]

The energy balance equation (5) is solved by the 2pnni and the 2p2cni.

The momentum balance equation of the solid-fluid system can be written to describe the linear elastic deformations during CO2 injection as [18]:

\[
\nabla \cdot (\Delta \sigma' + \Delta p_{\text{eff}} I) + \phi S_{n} (\rho_{n} - \rho_{w} g) = 0
\]

where \(\Delta \sigma'\) is the effective stress change. Equation (6) is implemented in the el2p model.

CO2 migration in fractured reservoirs can be simulated with the 2pdfm model using a lower-dimensional representations of the discrete fractures [19].

Table 1: DuMu\(^x\) models for GCS and the primary variables (modified after [18]).

| Individual models | Balance equations | Primary variables |
|-------------------|-------------------|-------------------|
| 2p                | Two-phase model   | mass, energy, Eq. (1) | \(p_{w}, S_{n}\) |
| 2p2e              | Two-phase two-component model | mass, energy, Eq. (4) and (5) | \(p_{w} S_{n}, \frac{S_{n}}{X_{w}^{CO2}}, \frac{S_{n}}{X_{w}^{H2O}}\) |
| 2pni              | Non-isothermal two-phase model | mass, energy, Eq. (4) and (5) | \(p_{w} S_{n}, T\) |
| 2p2cni            | Non-isothermal two-phase two-component model | mass, energy, Eq. (4) and (5) | \(p_{w} S_{n}, \frac{S_{n}}{X_{w}^{CO2}}, \frac{S_{n}}{X_{w}^{H2O}}, T\) |
| el2p              | Linear elastic two-phase model | mass, momentu, Eq. (1) and (6) | \(p_{w}, S_{n}, u_{x}, u_{y}, u_{z}\) |
| 2pdfm             | Two-phase discrete fracture model | mass, energy, Eq. (1) and variation | \(p_{w}, S_{n}\) |

In DuMu\(^x\) the mutual solubility model for the calculation of the phase composition for the CO2-H2O-NaCl fluid system is implemented according to the Spycher and Pruess approach [20]. Implemented constitutive relations and fluid properties for the DuMu\(^x\) CO2 models are summarized in Table 2.

Table 2 Fluid property and solubility functions implemented in DuMu\(^x\) (after [18]).

| Secondary variable | Symbol | Function of | Function used |
|--------------------|--------|-------------|---------------|
| Brine phase density | \(\rho_{b}\) | \(f(p, T, x_{b}^{\text{sal}}, x_{w}^{\text{CO2}})\) | [21] |
| CO2-rich phase density | \(\rho_{CO2}\) | \(f(T, p)\) | [22] |
| Brine phase viscosity | \(\mu_{b}\) | \(f(p, T, x_{b}^{\text{sal}})\) | [23][21] |
| CO2-rich phase viscosity | \(\mu_{CO2}\) | \(f(T, p)\) | [24] |
| Mass fraction water in CO2 | \(x_{b}^{H2O}|\ | \(f(T, p, x_{b}^{\text{sal}})\) | [20] |
| Relative permeability brine | \(k_{rel,b}\) | \(f(S_{b})\) | [25], [26] |
| Relative permeability CO2 | \(k_{rel,g}\) | \(f(S_{CO2})\) | [25], [26] |
| Capillary pressure | \(p_{c}\) | \(f(S_{b})\) | [25], [26] |
| Salinity | \(x_{b}^{\text{sal}}\) | | - |
| Diffusion coefficient of H2O in gas | \(D_{H2O}^{pm,b}\) | \(f(p, T)\) | [27] |
| Diffusion coefficient of CO2 in brine phase | \(D_{CO2}^{pm,b}\) | \(f(p, T)\) | |

3 Relevant studies applying DuMu\(^x\) for modelling GCS

The total number of scientific peer-reviewed journal articles using DuMu\(^x\) is more than 100 (Oct. 2018). We provide a summary of the key peer-reviewed articles using DuMu\(^x\) for simulating geological storage of CO2. The models used in these publications can simulate the most important thermo-hydro-mechanical-chemical and biological processes occurring during the lifetime of the CO2 storage reservoir. First DuMu\(^x\) overview paper summarizing the capabilities of the simulator has been peer reviewed and published in the journal Advances in Water Resources [9]. Until now, the publication was cited more than 224 times. Since 2008, DuMu\(^x\) was used and developed in 22 PhD theses.

CO2 storage sites

A number of numerical studies using DuMu\(^x\) were conducted to assess the storage efficiency in North German Basin and are described in [28], [29]. DuMu\(^x\) was applied to model the CO2 storage at the Ketzin pilot site located in Brandenburg, Germany, which is the longest-operating on-shore CO2 storage site in Europe [30], [31]. Intercomparison modelling studies on the Stuttgart formation at Ketzin pilot site were conducted in [32] using DuMu\(^x\), OpenGeosys, TOUGH2 and Eclipse 100. One
focus was to test the simulator capabilities on a complex heterogeneous reservoir. Their study concludes that DuMu$^\text{x}$ is a reliable simulator showing excellent agreement of simulated and observed pressures.

Walter et al. [33] provides estimates of the risk of brine discharge into freshwater aquifers due to CO$_2$ injection into geological formations. Key parameters influencing the CO$_2$ migration process from the gas reservoir in the Snøvit area, Barents Sea were determined by means of numerical modelling with DuMu$^\text{x}$ [34]. The authors identify potential migration pathways and their extent, i.e., faults, gas chimneys in an off-shore mostly sandy reservoir located in the Tubåen Formation (at 2560-2670 m below sea surface).

**Geomechanics**

The geomechanical effects are not only important for CO$_2$ injection in the geologic formations, but also for technologies such as geothermal stimulation, hydraulic fracturing, or wastewater injections. Here the understanding of the rock stresses and deformation is essential. Surpassing the strength of the rock can lead to failure and fractures in the caprock which may induce leakage. A volume-based model of fault reactivation in porous media and its implementation within DuMu$^\text{x}$ framework is discussed in [35]. The modelling approach is compared to the well-established models of Rutqvist et al. [36].

For understanding of the mechanical damage in weak sandstone reservoirs due to high CO$_2$ injection pressure a 2p2c-DuMu$^\text{x}$ – discrete element method coupled model is proposed in [37]. The capabilities of the approach are tested on the CO$_2$ pilot site located at Heletz, Israel [38], [39].

**Fractured Porous Media**

Modelling of single- and multi-phase flow in discrete fractured porous media was done in DuMu$^\text{x}$ by considering a box-method implementation [19], [40], [41] present the method and implementation in DuMu$^\text{x}$ of a discrete fracture model on the basis of a cell-centred finite volume scheme with multi-point flux approximation. Furthermore, an efficient workflow for modelling discrete fracture networks in DuMu$^\text{x}$ using the vertex-centered finite volume scheme for spatial discretization is presented in [42]. An upsampling technique of CO$_2$ migration in an interconnected fractured porous medium, i.e., extended multiple interacting continua (MINC) method is described in [19]. The comparison with the discrete fracture model shows very good agreement while obtaining computational speed-up factors over 100 times.

The development of a mathematical and numerical model for fracture flow in porous media using the eXtended finite element method (XFEM) is described in [43]. The XFEM is based on the hybrid-dimensional problem formulation and non-conforming meshing. A comparison of the box-DFM and XFEM methods is shown in [17]. The XFEM model in DuMu$^\text{x}$ however, has not been tested yet on CO$_2$ storage problems.

**Reactive transport**

Reactive transport models are also available under DuMu$^\text{x}$. A numerical model for microbially induced calcite precipitation is developed by [44] and compared to laboratory column experiments. The microbial induced calcite precipitation is related to the reduction of porosity and permeability and can potentially be used to cut off highly permeable pathways such as fractures and faults. This can be used to increase storage security near wellbores of CO$_2$ storage sites. The change of pore space (porosity, permeability) as a result of the reactive transport processes, e.g., mineral dissolution and precipitation, biomass growth is further discussed in [45].

A numerical model capable to reproduce reactive transport of a new category of tracers, termed kinetic interface sensitive (KIS) tracers in CO$_2$-brine systems is described in [46], [47]. KIS tracers are intended to be a monitoring technique providing information about the dynamic evolution of fluid-fluid interfacial area. This can be used to optimize the CO$_2$ injection such that the interfacial area is maximized. An increased CO$_2$-brine interfacial area leads to higher dissolution of CO$_2$ into the water phase and increase the efficiency of trapping. Following [48], CO$_2$ storage efficiency is defined as the ratio of the volume of CO$_2$ injected into an aquifer rock volume to the pore space in that volume.

**Benchmarking DuMu$^\text{x}$**

Benchmarks (code intercomparison) are important instruments for building confidence in the numerical simulator and better understanding the thermo-hydro-mechanical-chemical-biological processes occurring during injection and storing of the CO$_2$ in the subsurface. Benchmarking studies are a necessary to verify the algorithms and the software. [14], [15]

First code intercomparison studies related to GCS were done by [49] and [14]. Several workshops aimed at harmonizing and discussing the modelling results obtained with the various codes were held in Stuttgart (2008) and Svalbard (Norway, 2009). DuMu$^\text{x}$ has participated in these workshops showing a good performance (see [14]). Most commonly the sources of errors come from gridding, wrong assignment of model input parameters by human error, different interpretations of problem descriptions. A systematic approach for developing benchmarking concepts for CO$_2$ injection problems is proposed in [50]. Even though DuMu$^\text{x}$ has not directly participated in their benchmarking study, the authors address a problem (i.e., DSA#1) initially defined in [14].

Another benchmarking study on GCS, investigated the variability in model predictions obtained by different participants in response to the benchmark problem definition [15]. The conclusions of the study are very interesting, stressing the importance of modelling choices on the outcome of predictions even for simple, idealized problems. These choices the modeler has to take are similar to “real life” situations, where no problem statement is defined perfectly. Therefore, the choices are made as a function of the time availability, human and computational resources, independent interpretation of the problem. The sources of error in this case include the specific interpretation of the physical processes to be modelled, the choice of numerical scheme, upsampling procedure, if at all, and, the interpretation of problem definition and results.

A recent code intercomparison study involving DuMu$^\text{x}$ is described in [16]. The study was initiated within
the European Framework 7 funded project TRUST. Three benchmark test problems with increasing degree of complexity are defined to investigate and compare the effects arising during the CO2 injection, i.e., CO2 plume shape, fluid pressure and temperature evolution, deformation, etc. Simulators participating in the benchmarking are DuMu\textsuperscript{4}, PFLOTRAN, CODE\_BRIGHT, eWoms, and TOUGH2. The results are in good agreement with each other.

### 4 Summary and conclusions

CCS represents a viable mitigation technology which is ready to be implemented commercially at industrial scales. Numerical simulators are necessary tools to assist the dimensioning, planning and monitoring of operations during all stages of the project.

The paper gave an overview of DuMu\textsuperscript{4} simulator capabilities to address the complex phenomena accompanying the CO2 storage in geological formations. The models can deal with the non-isothermal multiphase flow, in fractured heterogeneous porous media systems, reactive transport, dissolution and mixing, modelling of rock deformation and stresses, (bio) mineralization, etc.

Our literature review on the possible geological storage locations in Romania showed that there are initiatives both on-shore and off-shore, either as storage in deep saline aquifers or as CCUS. The reviewed geological sites fulfill the conditions required for CO2 storage, i.e., a depth below 800 m, high permeabilities and high porosities.

Due to increasing physical complexity of the modelling tools benchmarking is receiving increasing attention from the scientific community. DuMu\textsuperscript{4} participated in more than three benchmarking studies aimed modelling CO2 storage in geological formations, where the results were compared with the ones of 23 academic and commercial simulators. Another benchmarking study was aimed at modelling single-phase flow in lower-dimensional fractured porous media. Further benchmarking studies are currently being planned and conducted, such as the call for participation “Verification benchmarks for single-phase flow in three-dimensional fractured porous media” [51].

Intercomparison studies have shown broad agreements in most areas but also highlighted sensitive points, mostly related to human/modeller choices in handling the benchmark problem.

The free open-source, numerical simulator DuMu\textsuperscript{4}, the manual, a list of current research projects, modelling examples and an up-to-date list of publications using the simulator can be obtained at the website [http://www.dumux.org](http://www.dumux.org).
