Abstract

**Background:** Cryptosporidiosis is a disease caused by infection with an intestinal coccidian parasite Cryptosporidium. Cryptosporidium species are the second leading cause of diarrheal disease and death in children in developing countries. Until now, no data have been available or published on its prevalence rate among children with diarrhoea in Sudan. This paper was therefore, designed to determine the prevalence rate of Cryptosporidium among diarrhoeic children under 5 years admitted to Kosti Teaching Hospital.

**Methods:** A hospital-based cross-sectional study including children with ages under 5 years old admitted to the paediatric section of the hospital between September 2020 and December 2020. A total of one-hundred and fifty stool samples were collected. All stool samples were examined using the modified Ziehl Neelsen (ZN) staining technique, and examined microscopically for Cryptosporidium infection.

**Results:** A total of 150 children were examined out of which 70 presented with diarrhoea. A greater prevalence of 19/70 (27.1%) of Cryptosporidium was observed in children with diarrhoea than children without diarrhoea 7/80 (8.8%). There was a significant relationship between the prevalence of Cryptosporidium and the presence of diarrhoea in children under 5 years in Kosti Teaching Hospital(P<0.05). It was found that a higher prevalence was registered among children using pipe water for drinking.

**Conclusions:** The overall prevalence of parasite detected was 17.3% among children admitted to Kosti Teaching Hospital. The prevalence rate of the infection among Children with diarrhoea was 27.1%. Studying the prevalence rate of cryptosporidiosis among diarrheic children may predict their health status, leading to a better diagnosis, treatment, and therefore, patients’ status improvement.

**Background**

Cryptosporidium species are single-celled coccidian parasites that cause the diarrheal disease cryptosporidiosis[1-4]. They can be found in soil, food, water, and on surfaces that have been contaminated with faecal matter from infected humans or animals. Cryptosporidiosis may occur via contaminated water used for irrigation or application of agricultural chemicals flood water contacting contaminated dump tank or flume water used for post-harvest washing of infected workers [5-9].

Cryptosporidiosis is a worldwide illness caused by the coccidian parasite Cryptosporidium, which infects numerous species of vertebrates, including humans. Watery diarrhoea is the most common symptom of the disease. Abdominal cramps, vomiting, nausea, dehydration, and weight loss are other symptoms associated with cryptosporidiosis. The onset of cryptosporidiosis is generally two to ten days after becoming infected with the parasite. Symptoms are usually self-limiting in healthy individuals. Diarrhoea and dehydration may be more severe and possibly life-threatening among individuals with weakened immune systems[10-13].
Cryptosporidiosis is usually diagnosed with microscopic detection of the parasite oocysts, oocyst antigens, or oocyst DNA in stool samples. For the detection of oocysts in stool, the sample must be concentrated using the formalin-ether sedimentation method prior to microscopic examination. The oocysts of Cryptosporidium in unconcentrated faecal smears can be easily observed by acid-fast or phenol–auramine staining methods [1,2,9,14-18].

About 30–50% of deaths in infants and children individuals resulting from cryptosporidiosis worldwide and it is the second after rotavirus leading cause of diarrhoea and deaths among children [1,9].

In developing countries or low-and-middle-income countries, the parasite was gradually associated with malnutrition and death caused by diarrhoea in children [5,6,19-23]. Cryptosporidiosis, caused by the Cryptosporidium parvum, is of great concern because of associated with economic losses and the public health significance in humans. Over two-hundred water-borne, food-borne, and zoonotic cryptosporidiosis outbreaks have been registered. Cryptosporidium spp. in economically low resource countries are the second cause of diarrheal illness and death in children and remains the only member of the major diarrheal diseases for which no consistently effective therapy is available [7,10,11,24-30].

Sudan is one of these countries, situated in Northeast Africa at the Nile Valley. Most epidemiological studies or surveys have reported and indicated that the infections caused by soil-transmitted helminths, Schistosoma spp., food- and water-borne protozoa, and Plasmodium spp., are endemic in Sudan [12-14,17]. However, limited and less information is available on the prevalence rate of cryptosporidiosis among children in Sudan, and especially among children with diarrhoea. The aim of this study is to study the prevalence of Cryptosporidiosis among children with diarrhoea attending to Kosti Teaching Hospital, White Nile State, Sudan.

**Materials And Methods**

**Study area**

The research was conducted at the paediatric section and clinical laboratory department of Kosti Teaching Hospital, Kosti, Sudan. This Hospital is serving customers from Kosti city and its surrounding cities in the State. Kosti city is one of the major cities in Sudan that lies south of Khartoum, the capital of Sudan, and stands on the western bank of the White Nile river opposite Rabak (the capital of the White Nile state) where there is a bridge. However, the locality is composed of five administrative units. It is bordered by Eldewiem locality in the north, Rabak locality in the east, Al salam locality in the south, and Tendalty locality in the west. The most important water resource rainwater and while Nile. Most activities are grazing, agriculture, trade, and fishing.

**Study design**

This study was a hospital-based cross-sectional study conducted at Kosti Teaching Hospital Laboratory between the first of September and 30th of December, 2020. All Participants consulted or hospitalized in...
the paediatric section were included. A consecutive sampling method was performed, from which those who met our inclusion criteria and agreed to our research were directly included and selected.

**Study population**

The main population of this study were Children under or equal the age 5 years admitting Kosti Teaching Hospital.

**Inclusion criteria**

The study was restricted to children under or equal the age 5 years that have diarrhoea and without diarrhoea whose parents/guardians agreed for their children after obvious explanation for the objectives of our study in English and Arabic.

**Exclusion criteria**

Children above 5 years were excluded and some of those children under or equal 5 years whose parents/guardians did not agree to our study. Additionally, we excluded children whose parents could not give a clear age for them.

**Ethical considerations**

The study was approved by the Institutional Ethics Committee of Faculty of Medical Laboratory Sciences, University of El Imam El Mahdi.

**Data collection**

Questionnaires were performed to gather demographic data that included; name, age, sex, clinical symptoms including diarrhoea, patient's residence, presence of toilet facility, sources of drinking water. This questionnaire was appropriated or adapted from the research by Tombang A N et al in Cameron [1].

**Stool sample collection**

Parents/guardians of children with gastrointestinal symptoms (with diarrhoea or without diarrhoea) were given stool containers labelled to collect one stool sample on the time of collection. They were explained how to collect suitable amount of stool in the stool containers and send them to the laboratory as soon as possible.

**Stool sample handling and storage**

Suitable gloves were performed to take or handle the containers. The samples were checked for the stool quantity and also the physical examination was recorded. The labels of the containers were also checked and matched to the corresponded questionnaires. A fresh stool samples were kept and preserved at - 20 °C in the fridge in the clinical laboratory for investigations at the end of each working day.
**Modified Ziehl Neelsen (mZN) staining technique:**

The stool samples were took from the laboratory fridge and putted at room temperature before faecal smears were prepared on microscope slides using a wooden stick applicators. Then the smears were left on racks to air dry.

**Method**

The slides were put in staining racks for fixation in absolute methanol for three minutes followed by a strong carbol fuchsin stain for 15 minutes. Then the slide was rinsed in tap water. A decolorization made by add 1% hydrochloric acid alcohol for 15 seconds, and rinsing in tap water. Then a counterstain 1% methylene blue added for 30 seconds, rinse well, and left to air dry. The stained slides were investigated and examined using 40x and 100x objectives and the presence or absence of Oocysts was registered.

**Results**

Oocysts are round to ovoid in shape, and the size usually ~ 4-6 µm in diameter. They are acid-fast staining. The sporulated structures or forms can be appeared as red crescentic bodies, and the sporozoites in the Oocysts, can be seen in unstained wall. The quantity of oocysts was determined as 1+ (1-10 oocysts/preparation); 2 + (11-50 oocysts/preparation); and 3 + (>50 oocysts/preparation).

**Statistical analysis:**

Data will be recorded and then analyzed using the Chi-square test by a statistical package of social science (SPSS version 21) program. P values < 0.05 will be considered significant for all statistical analysis.

**Results**

**Socio-demographic characteristics of participants**

A total of 150 children with the ages under or equal 5 years old were enrolled in this study. The mean age of the children was 46.8 (SD = 17.7) years and the median age was 60 months. More than half 85 (56.7%) of the children were male. Also, as concerns a total of 137 (91.3%) or 13 (8.7%), have latrines or without latrines in their homes respectively (Table 1).

**The diarrhoea and stool consistency from children within the ages under or equal 5 years in Kosti (n = 150)**

A total of 70/150 (46.7%) participants were presented with diarrhoea (watery/mucoid stool, and the remaining 80/150 (53.3%) children were presented with formed/semi-formed stool.
Prevalence of Cryptosporidium within age groups and the presence/absence of diarrhoea

Table 2 shows the age group less than 30 months that recorded a 10/63 (15.8%) prevalence with respect to a 16/87 (18.4%) for the age group equal 60 months. The participants that presented with diarrhoea recorded a 19/70 (27.1%) prevalence while those that did not present with diarrhoea recorded a 7/80 (8.8%) prevalence (Table 2).

Prevalence of Cryptosporidium among children under or equal the ages 5 years in Kosti that presented with diarrhoea

The overall prevalence of 26/150 (17.3%) for Cryptosporidium among children admitted to Kosti Teaching Hospital. High prevalence of Cryptosporidium (19/70, 27.1%) was observed among children have diarrhoea than children without diarrhoea (7/80, 8.8%). There was a high relationship (p = 0.003) between prevalence of Cryptosporidium and the presence of diarrhoea among children of ages under or equal 5 years in the Kosti Teaching Hospital (Table 3).

Table 1. Demographics data of the studied patients:

| Characteristics          | Frequency (n=150) | Percentage % |
|--------------------------|-------------------|--------------|
| Age                      |                   |              |
| <5yrs                    | 63                | 42           |

**Discussion**

*Cryptosporidium* is among the four major pathogens causing diarrheal diseases in low-and-middle-income countries, especially in children. This parasite is recognized as a highly infectious enteric pathogen and is transmitted mainly by the faecal-oral route [1,2]. This current study aimed to determine the prevalence rate of Cryptosporidiosis among children with diarrhoea patients admitted to Kosti Teaching hospital, Kosti city, White Nile state in Sudan. One-hundred and fifty diarrhoeic stool samples were examined using firstly direct wet preparation and formal ether concentration technique, and secondly examined using modified ZN staining technique.
In our present findings the overall prevalence rate of cryptosporidiosis was 26 (17.3%) among children with diarrhoea admitted to the paediatrics emergency section at Kosti Teaching Hospital using modified ziehl neelsen technique. This result is more than the result obtained in Tanzania, Cameroon and Rwanda and benin [1,2,3,6] with 10.4, 8.93, 9.4%, and 5.8% respectively. High prevalence rate has also, been found in low-and-middle-income countries with high average rainfall such as Nigeria [5], 38.3%. Our result is in the line with the result obtained in residents in rural areas in White Nile state in Sudan, 13.3% and near to that result obtained in Iraq [4,7], 21.92%. This prevalence rate is probably justified by fact that Kosti is a city with improved access to drinkable water, latrine use, less faecal contamination rates, thus limiting the occurrence of parasitosis in general and cryptosporidiosis in particular. Also, this low prevalence may be explained by methodology, using microscopy which can be less sensitive than PCR.

Our relevance analysis explained the prevalence of cryptosporidiosis among diarrhoeic children was higher increase in males 18 (12%) than female 8 (5%). but there was no significant difference (p >0.05). The reason for these difference is not clear since they have the same exposure at crawling stage but may be probably due to the fact that the female has less activity and being at home most of the time. This result is in the line with results obtained in Iraq [4].

In the current findings a high detection or recovery of cryptosporidium parasite was detected among the age group of ve years 16 (10,7%) than the age under ve years old 10 (6,7%). This finding is in agreement with a research carried out in Germany, and Cameroon [8,1] and by Centers for Disease Control (CDC) in 2020 [9] where a greater prevalence rate was gained among children of the ages of 5 years than those under 5 years. In this age, the high prevalence is maybe related to the fact that this age group are usually more in danger of diarrhoea for this reason, those basal hygiene activities are unknown or not respected and pair with the truth that the immune system of the body is not well sophisticated [9]. This great prevalence rate of children with the ages equal to 5 years, because schooling ages in Sudan is usually around five years old. Also, in this age group this prevalence can be imputed to the truth that the crest of parasitism occurs at the ages of kindergarten and the ages of primary schools when community games and touch with contaminated and dirty soil. This perhaps for the reason this current research was conducted in Kosti an urban and civilian area with a multiracial population, where children find better care fed than children in rural areas where the rates of malnutrition may be greater.

Further investigations expressed the prevalence was high among children who consumed pipeline water 18 (12%) than the other sources of water. Despite pipeline water with a purification system which is the main source of water for most populations in Kosti city, this high prevalence rate may be related sometime to the stopping of water purification system and it may be associated with economic improvement. The risk of using contaminated bare hands for feeding children may enable the transmission of foodborne diseases like Cryptosporidiosis from infected adults to children. These practices can generate big chances for the ingestion of contaminated food and water with oocysts shed from infected individuals with Cryptosporidium. This elaborates why Cryptosporidium is ranked 5th among the most important foodborne parasites globally [2, 5,7,30].
Conclusion

The overall prevalence of Cryptosporidiosis among children under or equal 5 years that admitted to Kosti Teaching Hospital was 17.3%. The Prevalence rate among children that have diarrhoea was 27.1%. Children whose parents were using pipe water for drinking registered a higher prevalence. Additionally, there is an association between Cryptosporidium and diarrhoea among children of ages under or equal 5 years admitted with diarrhoea in Kosti. Our findings clearly explained that Cryptosporidium is an essential causative agent of diarrhoea for children in Kosti. It necessary to build or improve more water purification systems and sanitation facilities to help the access of population of this area to clean drinking water for preventing cryptosporidium infection. Health education and personal hygiene programs should be held to teach the people how to avoid the infection.

Limitation of the study:

Freezing and thawing of stool samples may lead to fragmentation of oocysts and undercounting.

Declarations

Ethics approval and consent to participate

The Institutional Ethics Committee of Faculty of Medical Laboratory Sciences, University of El Imam El Mahdi approved the study. As children under or equal to the age of 5 years are involved in the study and their parents are involved in the questionnaire, and the informed consent is obtained from parents or legal guardians for themselves and for the involvement of their children. All participants were adequately informed about their rights, regulations, and all relevant guidelines or aspects of the research, including it is purpose and interview of the methods. And all methods were performed in accordance with the relevant guidelines and regulations/declaration of Helsinki.

Consent for publication

Not applicable

Availability of data and materials

The data used to support the findings of this study are available from the corresponding author upon request.

Competing interests

None declared

Funding:

None.
Authors' contributions:

AGT, AMA, EE, MAS, ME, ABO and SAM conceived and designed the study: AGT and AMA implement the study: AGT supervised the study: EE and MAS conducted data analysis: AGT, AMA, EE, MAS, ME, ABO and SAM interpreted study results: AGT wrote the first draft of the manuscript, while AMA, EE, MAS, and ME reviewed and corrected the manuscript. All authors read and approved the final manuscript.
