ON THE LANDAU-LIFSHITZ-GILBERT EQUATION WITH MAGNETOSTRICTION

L’. BANAS, M. PAGE, D. PRAETORIUS, AND J. ROCHAT

ABSTRACT. To describe and simulate dynamic micromagnetic phenomena, we consider a coupled system of the nonlinear Landau-Lifshitz-Gilbert equation and the conservation of momentum equation. This coupling allows to include magnetostrictive effects into the simulations. Existence of weak solutions has recently been shown in [12]. In our contribution, we give an alternate proof which additionally provides an effective numerical integrator. The latter is based on lowest-order finite elements in space and a linear-implicit Euler time-stepping. Despite the nonlinearity, only two linear systems have to be solved per timestep, and the integrator fully decouples both equations. Finally, we prove unconditional convergence—at least of a subsequence—towards, and hence existence of, a weak solution of the coupled system, as timestep size and spatial mesh-size tend to zero. Numerical experiments conclude the work and shed new light on the existence of blow-up in micromagnetic simulations.

1. Introduction

Throughout all technical areas, magnetic devices like sensors, recording heads, and magneto-resistive storage devices are quite popular and thus widely used. As their size decreases to a microscale, and the testing and development becomes more and more involved, the need for reliable and stable simulation tools as well as for a thorough theoretical understanding rises. In terms of mathematical physics, micromagnetic phenomena are modeled best by the Landau-Lifshitz-Gilbert equation (LLG), see (1) below. This nonlinear partial differential equation describes the behaviour of the magnetization of some ferromagnetic body under the influence of a so-called effective field. The mathematical challenges as well as its applicability to a wide range of real world problems makes LLG an interesting problem for mathematicians and physicists, but also for scientists from related fields like engineers and developers from high-tech industry.

In our contribution, we present and analyze a computationally attractive integrator to solve LLG numerically. Additionally, our analysis provides a constructive existence proof for weak solutions of the coupled system for LLG with magnetostriction and thus particularly includes the results of [12]. For the pure LLG equation, existence and non-uniqueness of weak solutions of LLG goes back to [3, 26] for a simplified effective field. For a review of the analysis of LLG, we refer to [13, 15, 22] or the monographs [20, 23] and the references therein. As far as the numerical analysis is concerned, mathematically reliable and convergent LLG integrators are found in [1, 2, 4, 5, 8, 9, 11, 16, 17, 19, 25]. Of utter interest are unconditionally convergent integrators which do not impose a coupling of spatial mesh-size \( h \) and time-step

Key words and phrases. LLG, magnetostriction, linear scheme, ferromagnetism, convergence.
size $k$ to ensure stability of the numerical integrator. Those integrators are split into two
groups; first, midpoint-scheme based integrators $[4, 25]$ which rely on the seminal work $[9]$
of BarEls & Prohl; second, projection-based first-order integrators $[2, 5, 11, 16, 17, 19]$
which build on the work $[1]$ of Alouges. All of the above integrators have in common that
they allow for constructive existence proofs of the corresponding problems. The idea, which
is also exploited in the current work, is to show boundedness of the computable discrete
solutions. Then, a compactness argument concludes the existence of weakly convergent
subsequences. Finally, those weak limits are identified as weak solutions of the coupled
system.

In our contribution, we extend the analysis of the aforementioned works for the projection
based integrators and show that these ideas can also be transferred to the coupled system
of LLG with magnetostriction. Even though the structure of the main proof in this work is
similar to the one from e.g. $[1, 5, 11]$ (and also the other works mentioned), we stress that
the individual ingredients are much harder to gain than for the coupling with stationary
equations $[11]$ or with the instationary Maxwell system $[5]$. First, unlike the Maxwell-LLG
system, the coupling to the conservation of momentum equation involves a nonlinear coupling
operator. Second, the field contribution which accounts for magnetostriction, does not only
depend on the displacement, but also on its spatial derivative. For these two reasons, the
analysis requires new mathematical tools and therefore complicates the convergence proof.
In contrast to the existing literature, we thus extend the approach from $[1]$ and analyze a
nonlinear coupling of LLG to a second time-dependent PDE. The contributions of this work
as well as the advances over the state of the art can be summarized as follows:

- We include the magnetostrictive field contribution into the numerical analysis as well
  as into the algorithm to account for elastic effects on a microscale. This allows to
  conduct more precise simulations in certain applications.
- We give a new and constructive proof for the existence of weak solutions for LLG
  with magnetostriction by providing a numerical integrator which is mathematically
  guaranteed to converge to a weak solution of the coupled system of LLG with mag-
  netostriction.
- The proposed integrator is unconditionally convergent towards a weak solution as
  soon as timestep-size $k$ and spatial mesh-size $h$ tend to zero, independently of each
  other. For midpoint-scheme based integrators $[4, 9, 25]$, unconditional convergence
  is theoretically proved. However, the solution of the nonlinear system requires either
  a heuristical solver or an appropriate fixed-point iteration. The latter is used in $[4,$
  $9, 25]$, but the resulting explicit scheme again involves a coupling of $h$ and $k$ to
guarantee convergence and avoid instabilities.
- The proposed algorithm is extremely attractive from a computational point of view:
  Since the two equations are fully decoupled, the implementation is easy and only
  two linear systems have to be solved per timestep. Contrary, midpoint-scheme based
  integrators $[4, 9, 25]$ have to solve one large nonlinear system per timestep, and the
decoupling has not been thoroughly analyzed $[4]$.
- We provide a numerical comparison between the extended Alouges-type integrator
  and an integrator based on the midpoint scheme $[25]$. Empirically, the numerical re-
  sults show that our integrator works with larger timesteps than the midpoint scheme.
  In particular, in our setting the computations based on the proposed integrator turn
out to be much faster. This gives empirical evidence that the fixed-point iteration for the midpoint scheme indeed poses a computational bottleneck.

Outline. The remainder of this paper is organized as follows: In Section 2, we state the mathematical model for the coupled system of LLG with magnetostriction and recall the notion of a weak solution (Definition 1). In Section 3, we collect some notation and preliminaries, as well as the definition of the discrete ansatz spaces. In Section 4, we write down our numerical integrator in Algorithm 2, and Section 5 is devoted to our main convergence result (Theorem 4) and its proof. Finally, numerical examples concludes the work in Section 6.

2. Model Problem

The evolution of the magnetization of a ferromagnetic body \( \Omega \) during some time interval \((0,T)\) is mathematically modeled by the Landau-Lifshitz-Gilbert equation (LLG) which in dimensionless form reads

\[
\mathbf{m}_t - \alpha \mathbf{m} \times \mathbf{m}_t = -\mathbf{m} \times \mathbf{H}_{\text{eff}} \quad \text{in } \Omega_T := (0,T) \times \Omega
\]

(1a)

Here, \( \mathbf{m} : \Omega_T \to \mathbb{S}^2 := \{ x \in \mathbb{R}^3 : |x| = 1 \} \) denotes the sought magnetization, and \( \mathbf{H}_{\text{eff}} \) is the so-called effective field that consists of several energy contributions each of which models a certain micromagnetic effect. More precisely, in our work, the effective field consists of the exchange contribution \( \Delta \mathbf{m} \), the magnetostrictive component \( \mathbf{h}_m \), and all other stationary and lower-order effects are collected in some general field contribution \( \pi(\mathbf{m}) \), i.e.

\[
\mathbf{H}_{\text{eff}} = C_e \Delta \mathbf{m} + \mathbf{h}_m - \pi(\mathbf{m}).
\]

(1b)

The general energy contribution \( \pi(\mathbf{m}) \), is only assumed to fulfill a certain set of properties, see (20)–(21), and we emphasize that this particularly includes the case \( \mathbf{H}_{\text{eff}} = C_e \Delta \mathbf{m} + \mathbf{h}_m + C_{\text{ani}} D \Phi(\mathbf{m}) + P(\mathbf{m}) - \mathbf{f} \). Here, \( \Phi(\mathbf{m}) \) denotes the crystalline anisotropy density and \( \mathbf{f} \) is a given applied field. The contribution \( P(\mathbf{m}) \) stands for the nonlocal strayfield. The constants \( C_e, C_{\text{ani}} > 0 \) denote the exchange and anisotropy constant, respectively. To keep the presentation simple, we did not include the additional coupling to the full Maxwell equations as in [5]. We stress, however, that this extension is straightforward and, with the combined techniques from this work and [5], one could consider a coupled system of full Maxwell LLG with the conservation of momentum equation to account for magnetostrictive effects. The combined results from [5] and the current work would then directly transfer to the coupled case and we would still derive unconditional convergence. Moreover, with the techniques from [11], it is straightforward to rigorously include a numerical approximation \( \pi_h(\cdot) \) of \( \pi(\cdot) \) into the convergence analysis.

For a bounded Lipschitz domain \( \Omega \subset \mathbb{R}^3 \) and a time interval \((0,T)\), we now aim to solve (1a) on \( \Omega_T \) supplemented by the initial and boundary conditions

\[
\mathbf{m}(0) = \mathbf{m}^0 \in H^1(\Omega; \mathbb{S}^2) \quad \text{and} \quad \partial_n \mathbf{m} = 0 \text{ on } (0,T) \times \partial \Omega.
\]

(1c)

The constraint \( |\mathbf{m}^0| = 1 \) almost everywhere in \( \Omega \) models the fact that we consider a constant temperature below the Curie point. Multiplication of (1a) with \( \mathbf{m} \) yields \( \partial_t |\mathbf{m}|^2 = 2 \mathbf{m} \cdot \mathbf{m}_t = 0 \). Hence, the modulus \( |\mathbf{m}| = 1 \) is preserved in time. By imposing the modulus constraint on \( \mathbf{m}^0 \), this guarantees \( |\mathbf{m}(t)| = 1 \) for almost all times \( t \in (0,T) \).
For modeling the magnetostrictive component, we follow the approach of Visintin [26]. Here, the magnetostrictive field reads

\[ h_m : \Omega_T \rightarrow \mathbb{R}^3, \quad (h_m)_q = (h_m(u, m))_q := \sum_{i,j,p=1}^{3} \lambda_{ijpq}^m \varepsilon_{ij}(m)_p, \quad (2) \]

where \((\cdot)_p\) denotes the \(p\)-th component of a vector field. We implicitly assume linear dependence of the stress tensor \(\sigma = \{\sigma_{ij}\}\) on the elastic part of the total strain \(\varepsilon^e = \{\varepsilon_{ij}^e\}\) which is the converse form of Hook’s law, i.e.

\[ \sigma := \lambda^e \varepsilon^e(u, m) : \Omega_T \rightarrow \mathbb{R}^{3 \times 3}, \quad \sigma_{ij} = \sum_{p,q=1}^{3} \lambda_{ijpq}^e \varepsilon_{pq}^e, \quad (3) \]

\[ \varepsilon^e(u, m) := \varepsilon(u) - \varepsilon^m(m) : [0, T] \times \Omega \rightarrow \mathbb{R}^{3 \times 3}, \quad (4) \]

where \(u : \Omega_T \rightarrow \mathbb{R}^3\) denotes the displacement vector field. The total strain is defined by the symmetric part of the gradient of \(u\), i.e.

\[ \varepsilon_{ij}(u) := \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right), \quad (5) \]

and the magnetic part of the total strain by

\[ \varepsilon^m(m) := \lambda^m \text{mm}^T : \Omega_T \rightarrow \mathbb{R}^{3 \times 3}, \quad \varepsilon_{ij}^m(m) = \sum_{p,q=1}^{3} \lambda_{ijpq}^m (m)_p (m)_q. \quad (6) \]

In addition, we assume both material tensors \(\lambda \in \{\lambda^e, \lambda^m\}\) to be symmetric \((\lambda_{ijpq} = \lambda_{jipq} = \lambda_{ijqp} = \lambda_{pqij})\) and positive definite

\[ \sum_{i,j,p,q=1}^{3} \lambda_{ijpq} \xi_{ij}^2 \geq \lambda^e \sum_{i,j=1}^{3} \xi_{ij}^2 \quad (7) \]

with bounded entries, i.e. there exists some \(\lambda^e > 0\) to be constant and independent of the deformation. The stress tensor \(\sigma\) and the displacement field \(u\) (where we assume no external forces) are finally coupled via the conservation of momentum equation

\[ \varrho u_{tt} - \nabla \cdot \sigma = 0 \quad \text{in} \ \Omega_T. \quad (8a) \]

Here, we assume the mass density \(\varrho > 0\) to be constant and independent of the deformation. Equation (8a) is additionally supplemented by the initial and boundary conditions

\[ u(0) = u^0 \in \Omega, \quad u_t(0) = u^0 \in \Omega, \quad \text{and} \quad u = 0 \text{ on } \partial \Omega. \quad (8b) \]

Altogether, we thus aim to solve the coupled problem

\[ \begin{cases} m_t - \alpha m \times m_t = -m \times H_{\text{eff}} \\ \varrho u_{tt} - \nabla \cdot \sigma = 0, \end{cases} \quad (9) \]

subject to the stated initial and boundary conditions.
Using the above boundary conditions, Hook’s relation (3), the definition of the total strain tensor (4), and the symmetry of the tensors $\mathbf{X}^e$ and $\mathbf{X}^m$, we obtain the following variational formulation of (8a)

$$
(\mathbf{e} \mathbf{u}_t(t), \varphi) + (\mathbf{X}^e \varepsilon(\mathbf{u})(t), \varepsilon(\varphi)) = (\mathbf{X}^m \varepsilon^m(\mathbf{m})(t), \varepsilon(\varphi)) \quad \text{for all } \varphi \in H^1_0(\Omega).
$$

Given these notations, we now define our notion of a weak solution for the coupled LLG-magnetostriction system (9), which is the same as in [12].

**Definition 1.** The tupel $(\mathbf{m}, \mathbf{u})$ is called a weak solution of LLG with magnetostriction, if for all $T > 0$,

(i) $\mathbf{m} \in H^1(\Omega_T)$ with $|\mathbf{m}| = 1$ almost everywhere in $\Omega_T$ and $\mathbf{u} \in H^1(\Omega_T)$;

(ii) for all $\varphi \in C^\infty(\Omega_T)$ and $\zeta \in C^\infty([0, T) \times \Omega)$, we have

$$
\int_{\Omega_T} \langle \mathbf{m}_t, \varphi \rangle - \alpha \int_{\Omega_T} \langle (\mathbf{m} \times \mathbf{m}_t), \varphi \rangle = -C_{\text{exch}} \int_{\Omega_T} \langle (\nabla \mathbf{m} \times \mathbf{m}), \nabla \varphi \rangle
$$

$$
+ \int_{\Omega_T} \langle (\mathbf{h}_m \times \mathbf{m}), \varphi \rangle - \int_{\Omega_T} \langle (\pi(\mathbf{m}) \times \mathbf{m}), \varphi \rangle
$$

$$
- \varrho \int_{\Omega_T} \langle \mathbf{u}_t, \zeta \rangle + \int_{\Omega_T} \langle \mathbf{X}^e \varepsilon(\mathbf{u}), \varepsilon(\zeta) \rangle = \int_{\Omega_T} \langle \mathbf{X}^e \varepsilon(\mathbf{m}), \varepsilon(\zeta) \rangle + \int_{\Omega} \langle \dot{\mathbf{u}}, \zeta(0, \cdot) \rangle
$$

(iii) there holds $\mathbf{m}(0, \cdot) = \mathbf{m}_0^0$ and $\mathbf{u}(0, \cdot) = \mathbf{u}_0$ in the sense of traces;

(iv) for almost all $t' \in (0, T)$, we have bounded energy

$$
\|\nabla \mathbf{m}(t')\|_{L^2(\Omega)}^2 + \|\mathbf{m}_t\|_{L^2(\Omega_T)}^2 + \|
abla \mathbf{u}(t')\|_{L^2(\Omega)}^2 + \|\mathbf{u}_t(t')\|_{L^2(\Omega)}^2 \leq C_1,
$$

where $C_1$ is independent of $t$ and depends only on $|\Omega|, \mathbf{m}_0, \mathbf{u}_0$, and $\dot{\mathbf{u}}_0$.

### 3. Preliminaries

For time discretization, we impose a uniform partition $0 = t_0 < t_1 < \ldots < t_N = T$ of the time interval $[0, T]$. The timestep size is denoted by $k = k_j := t_{j+1} - t_j$ for $j = 0, \ldots, N - 1$. For each (discrete) function $\varphi$ which is continuous in time, $\varphi^j = \varphi(t_j)$ denotes the evaluation at time $t_j$. For the time derivatives in the conservation of momentum equation (10), we use difference quotients of first and second order which are denoted by

$$
d_t z_i = \frac{z_i - z_{i-1}}{k}, \quad d^2_t z_i = \frac{d_t z_i - d_t z_{i-1}}{k} = \frac{z_i - 2z_{i-1} + z_{i-2}}{k^2}.
$$

For spatial discretization, let $\mathcal{T}_h$ be a quasi-uniform, regular triangulation of the polyhedral bounded Lipshitz domain $\Omega \subset \mathbb{R}^3$ into tetrahedra. The spatial mesh-size is denoted by $h$. By $S^1(\mathcal{T}_h)$, we denote the lowest-order Courant FEM space of globally continuous and piecewise affine functions from $\Omega$ to $\mathbb{R}^3$, i.e.

$$
S^1(\mathcal{T}_h) := \{ \phi_h \in C(\overline{\Omega}; \mathbb{R}^3) : \phi_h|_K \in P_1(K) \text{ for all } K \in \mathcal{T}_h \}.
$$

By $\mathcal{I}_h : C(\overline{\Omega}; \mathbb{R}^3) \to S^1(\mathcal{T}_h)$, we denote the nodal interpolation operator onto this space. The set of nodes of the triangulation $\mathcal{T}_h$ is denoted by $\mathcal{N}_h$.

For the discretization of the magnetization $\mathbf{m}$ in the LLG equation (1a), we define the set of admissible discrete magnetizations by

$$
\mathcal{M}_h := \{ \phi_h \in S^1(\mathcal{T}_h) : |\phi_h(z)| = 1 \text{ for all } z \in \mathcal{N}_h \}.
$$
Furthermore, for $\phi_h \in \mathcal{M}_h$, let

$$K_{\phi_h} := \{ \psi_h \in \mathcal{S}^1(\mathcal{T}_h) : \psi_h(z) \cdot \phi_h(z) = 0 \text{ for all } z \in \mathcal{N}_h \}$$

be the discrete tangent space associated with $\phi_h$. Here, $x \cdot y$ stands for the usual Euclidean scalar product of $x, y \in \mathbb{R}^3$ which is sometimes also denoted by $\langle \cdot, \cdot \rangle$ to improve readability. The $L^2(\Omega)$ scalar product is denoted by $\langle \cdot, \cdot \rangle$ throughout. Due to the modulus constraint $m_t \cdot m = 0$, and thus $|m(t)| = 1$ almost everywhere in $\Omega_T$, we discretize the time variable $v(t_j) := m_t(t_j)$ in the discrete tangent space of $m_t$.

To discretize the equation of magnetoelasticity (10), we employ $S_0^1(\mathcal{T}_h) := S^1(\mathcal{T}_h) \cap H^1_0(\Omega)$. Furthermore, for $\phi \in \mathcal{M}_h$ and $m^0_t \in S_0^1(\mathcal{T}_h)$ be suitable approximations of the initial data obtained e.g. by projection. Further requirements on those initial data are specified below in Theorem 4. Finally, we define $d_t u^0_h$ as $\hat{u}_h^0$. Throughout this work, we write $A \lesssim B$ if there holds $A \leq CB$ for some $h$ and $k$ independent constant $C > 0$.

### 4. Algorithm

For discretization of the LLG equation, we follow the approach of ALOUGES [1] which has been generalized in [2] and GOLDENITS ET AL. [11, 18, 19]. The main idea is to introduce a new free variable $v \approx m_t$ and to interpret LLG as a linear equation in $v$. This ansatz exploits the formulation

$$\alpha m_t + m \times m_t = H_{\text{eff}} - (m \cdot H_{\text{eff}}) m,$$

which is equivalent to (1a) under the constraint $|m| = 1$ almost everywhere, see e.g. [18, Lemma 1.2.1]. The conservation of momentum equation is discretized in space by a standard FEM approach, and by finite differences in time. This approximation is in analogy to the work of BANAS AND SLODICKA [6], where the focus is on FEM discretizations for strong solutions of (1) with (8). In addition and for computational ease, the two equations can be decoupled. We propose and analyze the following algorithm:

**Algorithm 2.** Input: Initial data $m^0_h$ and $u^0_h$, parameter $0 \leq \theta \leq 1, \alpha > 0$. For $\ell = 0, \ldots, N - 1$ iterate:

(i) Compute unique solution $v^\ell_h \in \mathcal{K}_{m^\ell_h}$ such that for all $\varphi_h \in \mathcal{K}_{m^\ell_h}$, we have

$$\alpha(v^\ell_h, \varphi_h) + \langle (m^\ell_h \times v^\ell_h), \varphi_h \rangle = -C(c)(\nabla(m^\ell_h + \theta k v^\ell_h), \nabla \varphi_h) + \langle h_m(u^\ell_h, m^\ell_h), \varphi_h \rangle - \langle \pi(m^\ell_h), \varphi_h \rangle.$$

(ii) Define $m_h^{\ell+1} \in \mathcal{M}_h$ nodewise by $m_h^{\ell+1}(z) = \frac{m^\ell_h(z) + kv^\ell_h(z)}{|m^\ell_h(z) + kv^\ell_h(z)|}$ for all $z \in \mathcal{N}_h$.

(iii) Compute unique solution $u_h^{\ell+1} \in S_0^1(\mathcal{T}_h)$ such that for all $\psi_h \in S_0^1(\mathcal{T}_h)$, we have

$$g(a_h^\ell u_h^{\ell+1}, \psi_h) + \langle \lambda \varepsilon(u_h^{\ell+1}), \varepsilon(\psi_h) \rangle = \langle \lambda \varepsilon^m(m_h^{\ell+1}), \varepsilon(\psi_h) \rangle.$$

In the above algorithm, the discrete magnetostrictive contribution is given by

$$[h_m(u^\ell_h, m^\ell_h)]_q := \sum_{i,j,p=1}^3 \lambda^m_{ijpq} \sigma^h_{ij}(m^\ell_h)_p, \quad \text{with} \quad \sigma^h = \lambda^m(\varepsilon(u^\ell_h) - \varepsilon^m(m^\ell_h)).$$

Exploiting that we solve each of the two equations separately, we can immediately state well-posedness of Algorithm 2.
Lemma 3. Algorithm 2 is well defined, i.e. it admits unique discrete solutions \((v_h^\ell, m_h^{\ell+1}, u_h^{\ell+1})\) in each step \(\ell = 0, \ldots, N-1\) of the iteration. Moreover, we have \(\|m_h^\ell\|_{L^\infty(\Omega)} = 1\) for all \(\ell = 1, \ldots, N\).

**Proof.** We first show solvability of (16). We define the bilinear form

\[
a_1^\ell(\cdot, \cdot) : K_{m_h^\ell} \times K_{m_h^\ell} \to \mathbb{R}, \quad a_1^\ell(\phi, \varphi) := \alpha(\phi, \varphi) + \theta C_e k (\nabla \phi, \nabla \varphi) + ((m_h^\ell \times \phi), \varphi)
\]

and the linear functional

\[
L_1^\ell(\varphi) := C_e (\nabla m_h^\ell, \nabla \varphi) + (h_m(u_h^\ell, m_h^\ell), \varphi) - (\pi(m_h^\ell), \varphi).
\]

Then, (16) is equivalent to \(a_1^\ell(v_h^\ell, \varphi_h) = L_1^\ell(\varphi_h)\) for all \(\varphi_h \in K_{m_h^\ell}\). Note that \(a_1^\ell(\cdot, \cdot)\) is positive definite for \(\alpha > 0\), i.e. \(a_1^\ell(\varphi, \varphi) \geq \alpha \|\varphi\|_{L^2(\Omega)}^2\). Thus, by exploiting finite dimension, we see that there exists a unique \(v_h^\ell \in K_{m_h^\ell}\) which solves (16). Due to pointwise orthogonality of \(m_h^\ell\) and \(v_h^\ell\), and the Pythagoras theorem, we get \(|m_h^\ell(z) + kv_h^\ell(z)|^2 = |m_h^\ell(z)|^2 + k|v_h^\ell(z)|^2 \geq 1\) and thus even step (ii) of the above algorithm is well-defined. The bound \(\|m_h^\ell\|_{L^\infty(\Omega)} = 1\) can be seen by the normalization at the grid points in combination with barycentric coordinates and the convexity of each tetrahedron.

For the second equation (17), we consider the bilinear form

\[
a_2^\ell(\cdot, \cdot) : S_0^1(T_h) \times S_0^1(T_h) \to \mathbb{R}, \quad a_2(\zeta, \psi) := \frac{\theta}{k^2} (\zeta, \psi) + (\lambda^e \varepsilon(\zeta), \varepsilon(\psi))
\]

and the linear functional

\[
L_2^\ell(\psi) = (\lambda^e \varepsilon_m(m_h^{\ell+1}), \varepsilon(\psi)) + \frac{\theta}{k^2} (d^i u_h^\ell, \psi) + \frac{\theta}{k} (u_h^\ell, \psi).
\]

According to (7) and Korn’s inequality [10, Thm. 11.2.16], it holds that \(a_2(\psi, \psi) \geq \|\psi\|_{H^1(\Omega)}^2\). With this notation, (17) is equivalent to \(a_2(u_h^{\ell+1}, \psi_h) = L_2^\ell(\psi_h)\) for all functions \(\psi_h \in S_0^1(T_h)\), and hence, admits a unique solution \(u_h^{\ell+1} \in S_0^1(T_h)\) in each step of the loop. 

\[\square\]

5. **Main Theorem**

In this section, we aim to show that the preceding algorithm indeed converges towards the correct limit. Before we start with the actual analysis, we collect some general assumptions and some more notation. Throughout, we assume that the spatial meshes \(T_h\) are uniformly shape regular and satisfy the angle condition

\[
\int_\Omega \nabla \zeta_i \cdot \nabla \zeta_j \leq 0 \quad \text{for all hat functions } \zeta_i, \zeta_j \in S^1(\Omega) \text{ with } i \neq j.
\]

This somewhat technical condition is a crucial ingredient of the convergence proof, since it yields the discrete energy decay

\[
\|\nabla m_h^{\ell+1}\|_{L^2(\Omega)}^2 \leq \|\nabla (m_h^\ell + k v_h^\ell)\|_{L^2(\Omega)}^2.
\]

The estimate (19) is a direct consequence of the inequality \(\|\nabla I_m(m/|m|)\|_{L^2(\Omega)}^2 \leq \|\nabla I_m m\|_{L^2(\Omega)}^2\) which was proved by BARTELS in [7]. We like to emphasize that the angle condition is always fulfilled for tetrahedral meshes with dihedral angles that are smaller than \(\pi/2\), cf. [7], and easily preserved for uniform mesh-refinement. For \(x \in \Omega\) and \(t \in [t_\ell, t_{\ell+1})\) and for \(\gamma_h^\ell \in \{m_h^\ell, v_h^\ell, u_h^\ell\}\), we define the time approximations

\[
\gamma_{hk}^\ell(t, x) := \frac{t - t_\ell}{k} \gamma_h^{\ell+1}(x) + \frac{t_{\ell+1} - t}{k} \gamma_h^\ell(x), \quad \gamma_{hk}^-(t, x) := \gamma_h^\ell(x), \quad \gamma_{hk}^+(t, x) := \gamma_h^{\ell+1}(x).
\]
Note that $\gamma_{hk}^\ell(t, x) = \gamma_{h}^\ell(x) + (t - t_\ell)d_t^\ell \gamma_{h}^{\ell+1}(x)$. In addition, for $t \in [t_\ell, t_{\ell+1}]$, we define
\[
\hat{u}_{hk}(t, x) := d_t u_h^\ell(x) + (t - t_\ell) d_t^2 u_h^{\ell+1}(x), \quad \hat{u}_{hk}^-(t, x) := d_t u_h^\ell(x), \quad \hat{u}_{hk}^+(t, x) := d_t u_h^{\ell+1}(x).
\]
The next statement is the main theorem of this work and particularly includes the main result from [12].

**Theorem 4.** (a) Let $\theta \in (1/2, 1]$ and suppose that the meshes $\mathcal{T}_h$ are uniformly shape regular and satisfy the angle condition (18). Moreover, let the general energy contribution $\pi$ be uniformly bounded in $L^2(\Omega_T)$, i.e.
\[
\|\pi(n)\|_{L^2(\Omega_T)}^2 \leq C_\pi \quad \text{for all } n \in L^2(\Omega_T) \text{ with } n \leq 1 \text{ a.e. in } \Omega_T,
\]
with an $n$-independent constant $C_\pi > 0$ and assume weak convergence of the initial data, i.e. $m_0^h \rightharpoonup m^0$, $u_0^h \rightharpoonup u^0$ in $H^1(\Omega)$, as well as $\hat{u}_0^h \rightharpoonup \hat{u}^0$ in $L^2(\Omega)$ as $h \to 0$. Under these assumptions, we have strong $L^2(\Omega_T)$-convergence of $m_{hk}$ towards some function $m \in H^1(\Omega_T)$.

(b) Suppose that, in addition to the above assumptions, we have
\[
\pi(m_{hk}^-) \rightharpoonup \pi(m) \quad \text{weakly subconvergent in } L^2(\Omega_T).
\]
Then, the computed FE solutions $(m_{hk}, u_{hk})$ are weakly subconvergent in $H^1(\Omega_T) \times H^1(\Omega_T)$ towards some functions $(m, u)$, and those weak limits $(m, u)$ are a weak solution of LLG with magnetostriction. In particular, weak solutions exist and each weak accumulation point of $(m_{hk}, u_{hk})$ is a weak solution in the sense of Definition 1.

The proof will be done in roughly three steps.

(i) Boundedness of the discrete quantities and energies.
(ii) Existence of weakly convergent subsequences.
(iii) Identification of the limits with weak solutions of LLG with magnetostriction.

As mentioned, we first show the desired boundedness and start with some preliminary lemmata.

**Lemma 5.** The discrete magnetostrictive component can be estimated by the total strain of the discrete displacement, i.e.
\[
\|h_m(u^\ell_h, m^\ell_h)\|_{L^2(\Omega)}^2 \leq C_2 \|\varepsilon(u^\ell_h)\|_{L^2(\Omega)}^2 + C_3,
\]
for some constants $C_2, C_3 > 0$ that depend only on $\lambda$.

**Proof.** By definition of the magnetostrictive part, we immediately get
\[
\|h_m(u^\ell_h, m^\ell_h)\|_{L^2(\Omega)} \lesssim \lambda \|m^\ell_h\|_{L^\infty(\Omega)}^2 \|\sigma^h\|_{L^2(\Omega)}^2 \lesssim \|\sigma^h\|_{L^2(\Omega)}^2
\]
due to the normalization step. From the definition of the discrete stress tensor and the boundedness of the material tensors, we additionally get
\[
\|\sigma^h\|_{L^2(\Omega)}^2 \lesssim \lambda \|\varepsilon(u^\ell_h)\|_{L^2(\Omega)}^2 + \|\varepsilon^m(m^\ell_h)\|_{L^2(\Omega)}^2 \lesssim \|\varepsilon(u^\ell_h)\|_{L^2(\Omega)}^2 + C.
\]
This yields the assertion. □
Lemma 6. For $j = 1, \ldots, N$, there holds

\[
\|\nabla m_h^j\|_{L^2(\Omega)}^2 + (\theta - \frac{1}{2})k^2 \sum_{\ell=0}^{j-1} \|\nabla v_h^j\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2 \leq C_4 (\|\nabla m_h^0\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + C_5),
\]

for constants $C_4, C_5 > 0$ that depend only on $C_\pi$ as well as $C_2$ and $C_3$ from the previous lemma.

Proof. In (16), we use the special test function $\varphi_h = v_h^\ell \in K_m$ and get

\[
\alpha(v_h^\ell, v_h^\ell) + ((m_h^\ell \times v_h^\ell), v_h^\ell) = -C_e (\nabla(m_h^\ell + \theta k v_h^\ell), \nabla v_h^\ell) + \langle h_m(u_h^\ell, m_h^\ell), v_h^\ell \rangle - \langle \pi(m_h^\ell), v_h^\ell \rangle,
\]

whence

\[
\alpha|v_h^\ell|_{L^2(\Omega)}^2 + C_e \theta k \|\nabla v_h^\ell\|_{L^2(\Omega)}^2 = -C_e (\nabla(m_h^\ell, \nabla v_h^\ell) + \langle h_m(u_h^\ell, m_h^\ell), v_h^\ell \rangle - \langle \pi(m_h^\ell), v_h^\ell \rangle.
\]

Next, we use the fact that $\|\nabla m_h^{\ell+1}\|_{L^2(\Omega)}^2 \leq \|\nabla(m_h^\ell + k v_h^\ell)\|_{L^2(\Omega)}^2$, see (19), to obtain

\[
\frac{1}{2} \|\nabla m_h^{\ell+1}\|_{L^2(\Omega)}^2 \leq \frac{1}{2} \|\nabla m_h^\ell\|_{L^2(\Omega)}^2 + k(\nabla m_h^\ell, \nabla v_h^\ell) + \frac{k^2}{2} \|\nabla v_h^\ell\|_{L^2(\Omega)}^2 \\
\leq \frac{1}{2} \|\nabla m_h^\ell\|_{L^2(\Omega)}^2 - (\theta - 1/2) k^2 \|\nabla v_h^\ell\|_{L^2(\Omega)}^2
\]

We sum over the time intervals from 0 to $j - 1$, which yields for any $\nu > 0$

\[
\frac{1}{2} \|\nabla m_h^j\|_{L^2(\Omega)}^2 + \frac{\alpha k}{C_e} \sum_{\ell=0}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2
\]

\[
\leq \frac{1}{2} \|\nabla m_h^0\|_{L^2(\Omega)}^2 + \frac{k}{C_e} \sum_{\ell=0}^{j-1} \left[ \langle h_m(u_h^\ell, m_h^\ell), v_h^\ell \rangle - \langle \pi(m_h^\ell), v_h^\ell \rangle \right] - (\theta - 1/2) k^2 \sum_{\ell=0}^{j-1} \|\nabla v_h^\ell\|_{L^2(\Omega)}^2
\]

\[
\leq \frac{1}{2} \|\nabla m_h^0\|_{L^2(\Omega)}^2 + \frac{k}{4C_e \nu} \sum_{\ell=0}^{j-1} \left( \|h_m(u_h^\ell, m_h^\ell)\|_{L^2(\Omega)}^2 + \|\pi(m_h^\ell)\|_{L^2(\Omega)}^2 \right)
\]

\[
+ \frac{k^2}{C_e} \sum_{\ell=0}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2
\]

With Lemma 5 and the uniform boundedness (20) of $\pi(\cdot)$, we further obtain

\[
\text{RHS} \leq \frac{1}{2} \|\nabla m_h^0\|_{L^2(\Omega)}^2 + \frac{kC_2}{4C_e \nu} \sum_{\ell=0}^{j-1} \left( \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + C_3 \right) + C_\pi
\]

\[
+ \frac{k^2}{C_e} \sum_{\ell=0}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2
\]

\[
- (\theta - 1/2) k^2 \sum_{\ell=0}^{j-1} \|\nabla v_h^\ell\|_{L^2(\Omega)}^2.
\]
In total we thus derive
\[
\frac{1}{2}\|\nabla m_h^j\|^2_{L^2(\Omega)} + \frac{k}{C_e}(\alpha - \nu) \sum_{\ell=0}^{j-1}\|\phi_{\ell}^j\|^2_{L^2(\Omega)} + (\theta - \frac{1}{2})k^2 \sum_{\ell=0}^{j-1}\|\nabla \phi_{\ell}^j\|^2_{L^2(\Omega)} \\
\lesssim \frac{1}{2}\|\nabla m_0^j\|^2_{L^2(\Omega)} + \frac{kC_2}{4C_e\nu} \sum_{\ell=0}^{j-1}(\|\varepsilon(u_{\ell}^j)\|^2_{L^2(\Omega)} + C_3) + C\pi
\]
Taking \(\nu < \alpha\) thus yields the desired result. \(\square\)

Given the last two lemmata, we now aim to show boundedness of the discrete quantities involved in equation (17), i.e. boundedness of the discrete displacement approximations. The following result has basically already been stated in [6, Lemma 3]. Since we require some important modifications, we include the proof here.

**Proposition 7.** For any \(j = 1, \ldots, N\) and \(\frac{1}{2} \leq \theta \leq 1\), there holds
\[
\|d_t u_h^j\|^2_{L^2(\Omega)} + \sum_{\ell=1}^{j}\|d_t u_{\ell}^j - d_t u_{\ell-1}^j\|^2_{L^2(\Omega)} + \|\varepsilon(u_{\ell}^j)\|^2_{L^2(\Omega)} + \sum_{\ell=1}^{j}\|\varepsilon(u_{\ell}^j) - \varepsilon(u_{\ell-1}^j)\|^2_{L^2(\Omega)} \leq C_6
\]
for some \(h\) and \(k\) independent constant \(C_6 > 0\) which depends only on \(\mathbf{\lambda}^*\) and the constants \(C_4\) and \(C_5\) from Lemma 6.

**Proof.** We use \(\psi_h = u_{\ell+1}^j - u_\ell^j\) as test function in (17) and sum up for \(\ell = 0, \ldots, j-1\) to see
\[
\rho(d_t u_{\ell+1}^j - d_t u_{\ell}^j, d_t u_{\ell+1}^j) + (\mathbf{\lambda}^e(u_{\ell+1}^j), \varepsilon(u_{\ell+1}^j) - \varepsilon(u_{\ell}^j)) = (\mathbf{\lambda}^e \varepsilon(m_{\ell+1}^j), \varepsilon(u_{\ell+1}^j) - \varepsilon(u_{\ell}^j)).
\]
Recall that the Abel summation formula shows for any \(v_\ell \in \mathbb{R}\) and \(j \geq 0\)
\[
\sum_{\ell=0}^{j-1}(v_{\ell+1} - v_\ell, v_{\ell+1}) = \frac{1}{2}|v_j|^2 - \frac{1}{2}|v_0|^2 + \frac{1}{2}\sum_{\ell=0}^{j-1}|v_{\ell+1} - v_\ell|^2.
\]
This in combination with the symmetry and the positive definiteness (7) of \(\mathbf{\lambda}^e\) now yields
\[
\|d_t u_h^j\|^2_{L^2(\Omega)} + \sum_{\ell=1}^{j}\|d_t u_{\ell}^j - d_t u_{\ell-1}^j\|^2_{L^2(\Omega)} + \|\varepsilon(u_{\ell}^j)\|^2_{L^2(\Omega)} + \sum_{\ell=1}^{j}\|\varepsilon(u_{\ell}^j) - \varepsilon(u_{\ell-1}^j)\|^2_{L^2(\Omega)} \\
\leq \tilde{C} + C\sum_{\ell=1}^{j}(\mathbf{\lambda}^e \varepsilon(m_{\ell}^j), \varepsilon(u_{\ell}^j) - \varepsilon(u_{\ell-1}^j)),
\]
for some generic constants \(C, \tilde{C} > 0\). Note that the terms \(\|d_t u_h^j\|^2_{L^2(\Omega)} = \|\tilde{u}_h^0\|^2_{L^2(\Omega)}\) and \(\|\varepsilon(u_h^0)\|^2_{L^2(\Omega)}\) are uniformly bounded due to the assumed convergence of these initial data and are hidden in the constant \(\tilde{C}\).
Next, we rewrite the sum on the right-hand side as
\[
\sum_{\ell=1}^{j} (\lambda^\ell \varepsilon^m(m_h^\ell, \varepsilon(u_h^\ell) - \varepsilon(u_h^{\ell-1}))
\]
\[
= (\lambda^\ell \varepsilon^m(m_h^\ell, \varepsilon(u_h^\ell)) - (\lambda^\ell \varepsilon^m(m_h^{\ell-1}), \varepsilon(u_h^\ell)) - \sum_{\ell=1}^{j-1} (\lambda^\ell \varepsilon^m(m_h^\ell+1) - \lambda^\ell \varepsilon^m(m_h^\ell), \varepsilon(u_h^\ell))
\]
\[
= (\lambda^\ell \varepsilon^m(m_h^\ell, \varepsilon(u_h^\ell)) - (\lambda^\ell \varepsilon^m(m_h^{\ell-1}), \varepsilon(u_h^\ell)) - k \sum_{\ell=1}^{j-1} (\lambda^\ell \varepsilon^m(m_h^\ell+1), \varepsilon(u_h^\ell)).
\]

For any \( \eta > 0 \) and due to boundedness of \( \lambda^\varepsilon \), we further get
\[
\|d_t u_h^\ell\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|d_t u_h^\ell - d_t u_h^{\ell-1}\|_{L^2(\Omega)}^2 + \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\varepsilon(u_h^\ell) - \varepsilon(u_h^{\ell-1})\|_{L^2(\Omega)}^2
\]
\[
\lesssim 1 + k \sum_{\ell=1}^{j-1} \|d_t \varepsilon^m(m_h^{\ell+1})\|_{L^2(\Omega)}^2 + k \sum_{\ell=1}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \frac{1}{4\eta} \|\varepsilon^m(m_h^\ell)\|_{L^2(\Omega)}^2
\]
\[
+ \eta \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \|\varepsilon^m(m_h^{\ell-1})\|_{L^2(\Omega)}^2 + \|\varepsilon(u_h^0)\|_{L^2(\Omega)}^2.
\]

For sufficiently small \( \eta \), this can be simplified to
\[
\|d_t u_h^\ell\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|d_t u_h^\ell - d_t u_h^{\ell-1}\|_{L^2(\Omega)}^2 + \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\varepsilon(u_h^\ell) - \varepsilon(u_h^{\ell-1})\|_{L^2(\Omega)}^2
\]
\[
\lesssim 1 + k \left( \sum_{\ell=1}^{j-1} \|d_t \varepsilon^m(m_h^{\ell+1})\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 \right).
\]

Here, we again used convergence of the initial data. Using the boundedness and symmetry of \( \lambda^m \) in combination with boundedness of \( \|m_h^\ell\|_{L^\infty(\Omega)} \), straightforward calculation shows \( \|d_t \varepsilon^m(m_h^\ell)\|_{L^2(\Omega)} \lesssim \|d_t m_h^\ell\|_{L^2(\Omega)} \), cf. [24]. In combination with
\[
\|d_t m_h^\ell\|_{L^2(\Omega)} = \left\| \frac{m_h^\ell - m_h^{\ell-1}}{k} \right\|_{L^2(\Omega)} \leq \|v_h^{\ell-1}\|_{L^2(\Omega)},
\]

cf. [1, 2, 11] resp. [18, Lemma 3.3.2], this results in
\[
\|d_t u_h^\ell\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|d_t u_h^\ell - d_t u_h^{\ell-1}\|_{L^2(\Omega)}^2 + \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\varepsilon(u_h^\ell) - \varepsilon(u_h^{\ell-1})\|_{L^2(\Omega)}^2
\]
\[
\lesssim 1 + k \left( \sum_{\ell=1}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 \right).
\]
Next, we apply Lemma 6 to see
\[
\|d_t u_h^\ell\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|d_t u_h^\ell - d_t u_h^{\ell-1}\|_{L^2(\Omega)}^2 + \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\varepsilon(u_h^\ell) - \varepsilon(u_h^{\ell-1})\|_{L^2(\Omega)}^2 \\
\lesssim 1 + \left(\|m_h^0\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + k \sum_{\ell=1}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2\right) \\
\lesssim 1 + k \sum_{\ell=0}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2.
\]
Application of a discrete version of Gronwall’s lemma finally yields the assertion.

In order to show the desired $H^1(\Omega_T)$-convergence of $u$, we still need to show uniform boundedness of the $L^2(\Omega_T)$-part. This result is stated in the next corollary.

**Corollary 8.** Due to the boundary conditions employed, the Poincaré inequality in combination with Korn’s inequality shows
\[
\|u_h^j\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|u_h^\ell - u_h^{\ell-1}\|_{L^2(\Omega)}^2 \leq C_7\left(\|\nabla u_h^j\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\nabla(u_h^\ell - u_h^{\ell-1})\|_{L^2(\Omega)}^2\right) \\
\leq C_7\left(\|\varepsilon(u_h^j)\|_{L^2(\Omega)}^2 + \sum_{\ell=1}^{j} \|\varepsilon(u_h^\ell - u_h^{\ell-1})\|_{L^2(\Omega)}^2\right) \tag{26}
\]
for any $j = 1, \ldots, N$, where the constant $C_7 > 0$ stems from Poincaré’s inequality and thus only depends on the diameter of $\Omega$. According to Proposition 7, the right-hand side of (26) is uniformly bounded.

**Proposition 7** now immediately yields boundedness of the discrete magnetizations.

**Corollary 9.** For any $j = 1, \ldots, N$, there holds
\[
\|\nabla m_h^j\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|\nabla u_h^\ell\|_{L^2(\Omega)}^2 + \left(\theta - \frac{1}{2}\right)k^2 \sum_{\ell=0}^{j-1} \|\nabla v_h^\ell\|_{L^2(\Omega)}^2 \leq C_8 \tag{27}
\]
for some constant $C_8 > 0$ which depends only on $C_4, C_5,$ and $C_6$.

**Proof.** From Lemma 6, we get
\[
\|\nabla m_h^j\|_{L^2(\Omega)}^2 + \left(\theta - \frac{1}{2}\right)k^2 \sum_{\ell=0}^{j-1} \|\nabla v_h^\ell\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|v_h^\ell\|_{L^2(\Omega)}^2 \\
\leq C_4\left(\|m_h^0\|_{L^2(\Omega)}^2 + k \sum_{\ell=0}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 + C_5\right), \tag{28}
\]
By utilizing Proposition 7, we see $k \sum_{\ell=0}^{j-1} \|\varepsilon(u_h^\ell)\|_{L^2(\Omega)}^2 \leq |T|C_6$. The uniform boundedness of $\|\nabla m_h^0\|_{L^2(\Omega)}$ concludes the proof.

Next, we deduce the existence of convergent subsequences.
Lemma 10. Let $1/2 \leq \theta \leq 1$. Then, there exist functions $(m, u, \dot{u}) \in H^1(\Omega_T, S^2) \times H^1(\Omega_T) \times L^2(\Omega_T)$ such that

\begin{align}
\mathbf{m}_{hh} &\to \mathbf{m} \text{ in } H^1(\Omega_T) \\
\mathbf{m}_{hh}, \mathbf{m}_{hh}^+ &\to \mathbf{m} \text{ in } L^2(H^1), \\
\mathbf{m}_{hh}, \mathbf{m}_{hh}^+ &\to \mathbf{m} \text{ in } L^2(\Omega_T) \\
\mathbf{m}_{hh}, \mathbf{m}_{hh}^+ &\to \mathbf{m} \text{ pointwise almost everywhere in } \Omega_T, \\
u_{hh} &\to u \text{ in } H^1(\Omega_T) \\
u_{hh}, \nu_{hh}^+ &\to u \text{ in } L^2(H^1), \\
u_{hh}, \nu_{hh}^+ &\to u \text{ in } L^2(\Omega_T) \\
\dot{u}_{hh}, \dot{u}_{hh}^+ &\to \dot{u} \text{ in } L^2(\Omega_T). \tag{29a-29h}
\end{align}

Here, the convergence is to be understood for a subsequence of the corresponding sequences which is successively constructed, i.e. for arbitrary spatial mesh-size $h \to 0$ and timestep-size $k \to 0$, there exist subindices $h_n, k_n$, for which the above convergence properties are satisfied simultaneously. In addition, there exists some $v \in L^2(\Omega_T)$ with

$$v_{hh}^- \to v \text{ in } L^2(\Omega_T) \tag{30}$$

again for the same subsequence as above.

Proof. From Proposition 7, Corollary 8, and Corollary 9, we immediately get boundedness of all of those sequences. A compactness argument thus allows to successively extract convergent subsequences. Therefore, it only remains to show, that the corresponding limits coincide, i.e.

$$\lim \gamma_{hh} = \lim \gamma_{hh}^- = \lim \gamma_{hh}^+ \text{ with } \gamma_{hh} \in \{m_{hh}, u_{hh}, \dot{u}_{hh}\}.$$ 

To see this, we make use of the boundedness of two subsequent solutions. From Proposition 7, Corollary 8, and Corollary 9, we see that

\begin{align*}
\sum_{\ell=0}^{j-1} \|m_{h}^{\ell+1} - m_{h}^{\ell}\|_{L^2(\Omega)}^2 + \sum_{\ell=0}^{j-1} \|u_{h}^{\ell+1} - u_{h}^{\ell}\|_{L^2(\Omega)}^2 \\
+ \sum_{\ell=0}^{j-1} \|\varepsilon(u_{h}^{\ell+1}) - \varepsilon(u_{h}^{\ell})\|_{L^2(\Omega)}^2 + \sum_{\ell=0}^{j-1} \|d_t(u_{h}^{\ell+1}) - d_t(u_{h}^{\ell})\|_{L^2(\Omega)}^2
\end{align*}

is uniformly bounded. For the first sum, we used the inequality

$$\|m_{h}^{\ell+1} - m_{h}^{\ell}\|_{L^2(\Omega)}^2 \leq k^2 \|v_{h}^\ell\|_{L^2(\Omega)}^2,$$

see e.g. [1, 18]. We thus get

\begin{align*}
\|\gamma_{hh} - \gamma_{hh}^-\|_{L^2(\Omega_T)}^2 &= \sum_{\ell=0}^{N-1} \int_{t_{\ell}}^{t_{\ell+1}} \|\gamma_{h}^{\ell} + \frac{t - t_{\ell}}{k}(\gamma_{h}^{\ell+1} - \gamma_{h}^{\ell}) - \gamma_{h}^{\ell}\|_{L^2(\Omega)}^2 \\
&\leq k \sum_{\ell=0}^{N-1} \|\gamma_{h}^{\ell+1} - \gamma_{h}^{\ell}\|_{L^2(\Omega)}^2 \xrightarrow{h \to 0} 0,
\end{align*}

13
and analogously
\[
\| \gamma_{hk} - \gamma_{hk}^\pm \|_{L^2(\Omega_T)}^2 = \sum_{\ell=0}^{N-1} \int_{t_\ell}^{t_{\ell+1}} \| \gamma_h^\ell + \frac{t-t_\ell}{k} (\gamma_h^{\ell+1} - \gamma_h^\ell) - \gamma_h^{\ell+1} \|_{L^2(\Omega)}^2 \\
\leq \sum_{\ell=0}^{N-1} \int_{t_\ell}^{t_{\ell+1}} 2 \| \gamma_h^{\ell+1} - \gamma_h^\ell \|_{L^2(\Omega)}^2 \\
\leq 2k \sum_{\ell=0}^{N-1} \| \gamma_h^{\ell+1} - \gamma_h^\ell \|_{L^2(\Omega)}^2 \xrightarrow{h \to 0} 0.
\]

We thus conclude that the limits \( \lim \gamma_{hk} = \lim \gamma_{hk}^\pm \) coincide in \( L^2(\Omega_T) \). From the continuous inclusions \( H^1(\Omega_T) \subseteq L^2(H^1) \subseteq L^2(\Omega_T) \) and the uniqueness of weak limits, we even conclude the convergence properties in \( L^2(H^1) \), resp. in \( H^1(\Omega_T) \). By use of the Weyl theorem, we may extract yet another subsequence to see pointwise convergence, i.e. (29d). From

\[
\| |m| - 1| \|_{L^2(\Omega_T)} \leq \| |m| - |m^-_{hk}| \|_{L^2(\Omega_T)} + \| |m^-_{hk}| - 1| \|_{L^2(\Omega_T)}, \quad \text{and}
\| |m^-_{hk}(t, \cdot)| - 1| \|_{L^2(\Omega)} \leq h \max_{t_j} \| |\nabla m^l_{hk}| \|_{L^2(\Omega)} \xrightarrow{h \to 0} 0,
\]

we finally conclude \( |m| = 1 \) almost everywhere in \( \Omega_T \), which is the desired result. \( \square \)

In the remainder of this chapter, we will prove that the limiting tupel \((m, u)\) is indeed a weak solution in the sense of Definition 1. First, we identify the limit function \( v \) with the time derivative of \( m \). The following result can be found e.g. in [1].

**Lemma 11.** The limit function \( v \in L^2(\Omega_T) \) equals the time derivative of \( m \), i.e. \( v = \partial_t m \) almost everywhere in \( \Omega_T \). \( \square \)

We have now collected all ingredients for the proof of our main theorem.

**Proof of Theorem 4.** Let \((\zeta, \psi) \in C^\infty(\Omega_T) \times C^\infty([0, T); C^\infty(\Omega))\) be arbitrary. We define testfunctions by \((\varphi_h, \psi_h)(t, \cdot) := (\mathcal{I}_h(m^-_{hk} \times \zeta), \mathcal{I}_h\psi, \psi)(t, \cdot)\). With the notation from above, we integrate equation (16) in time to obtain

\[
\alpha \int_0^T (v^-_{hk}, \varphi_h) + \int_0^T \left( (m^-_{hk} \times v^-_{hk}), \varphi_h \right) = -C_\epsilon \int_0^T (\nabla (m^-_{hk} + \theta k v^-_{hk}), \nabla \varphi_h) \\
+ \int_0^T \left( h_m(u^-_{hk}, m^-_{hk}), \varphi_h \right) - \int_0^T \left( \pi(m^-_{hk}), \varphi_h \right).
\]

Then the magnetostrictive component is again given by

\[
[h_m(u^-_{hk}, m^-_{hk})]_\ell := \sum_{i,j,p} \lambda^m_{ijpq} \sigma^{hk}_{ij}(m^-_{hk})_{p}, \quad \text{with} \quad \sigma^{hk} = \chi(\varepsilon(u^-_{hk}) - \varepsilon^m(m^-_{hk})).
\]
The definition \( \varphi_h(t, \cdot) := I_h(\mathbf{m}_{hk} \times \zeta)(t, \cdot) \) and the approximation properties of the nodal interpolation operator show
\[
\int_0^T \left( (\alpha \mathbf{v}_{hk}^- + \mathbf{m}_{hk}^\top \times \mathbf{v}_{hk}^-), (\mathbf{m}_{hk}^\top \times \zeta) \right) + k \theta \int_0^T \left( \nabla \mathbf{v}_{hk}^-, \nabla (\mathbf{m}_{hk}^\top \times \zeta) \right) + C e \int_0^T \left( \nabla \mathbf{m}_{hk}^-, \nabla (\mathbf{m}_{hk}^\top \times \zeta) \right) - \int_0^T \left( \mathbf{h}_m(\mathbf{u}_{hk}^-, \mathbf{m}_{hk}^-), (\mathbf{m}_{hk}^\top \times \zeta) \right) + \int_0^T \left( \pi(\mathbf{m}_{hk}^-), (\mathbf{m}_{hk}^\top \times \zeta) \right) = O(h).
\]

Passing to the limit and using the strong \( L^2(\Omega_T) \)-convergence of \( (\mathbf{m}_{hk}^\top \times \zeta) \) towards \( (\mathbf{m} \times \zeta) \), we get
\[
\int_0^T \left( (\alpha \mathbf{v}_{hk}^- + \mathbf{m}_{hk}^\top \times \mathbf{v}_{hk}^-), (\mathbf{m}_{hk}^\top \times \zeta) \right) \rightarrow \int_0^T \left( (\alpha \mathbf{m}_0 + \mathbf{m} \times \mathbf{m}_0), (\mathbf{m} \times \zeta) \right),
\]
\[
k \theta \int_0^T \left( \nabla \mathbf{v}_{hk}^-, \nabla (\mathbf{m}_{hk}^\top \times \zeta) \right) \rightarrow 0, \quad \text{and}
\]
\[
\int_0^T \left( \nabla \mathbf{m}_{hk}^-, \nabla (\mathbf{m}_{hk}^\top \times \zeta) \right) \rightarrow \int_0^T \left( \nabla \mathbf{m}, \nabla (\mathbf{m} \times \zeta) \right),
\]
as \( (h, k) \rightarrow (0, 0) \), cf. [1, Proof of Thm. 2]. Here, we have used the boundedness of \( k \| \nabla \mathbf{v}_{hk}^- \|_{L^2(\Omega_T)} \) which follows from \( \theta \in (1/2, 1) \), see Corollary 9. Next, the weak convergence of \( \pi(\mathbf{m}_{hk}^-) \) from (21) yields
\[
\int_0^T \left( \pi(\mathbf{m}_{hk}^-), (\mathbf{m}_{hk}^\top \times \zeta) \right) \rightarrow \int_0^T \left( \pi(\mathbf{m}), (\mathbf{m} \times \zeta) \right).
\]

As for the magnetostrictive component, we have to show
\[
\mathbf{h}_m(\mathbf{u}_{hk}^-, \mathbf{m}_{hk}^-) \rightharpoonup \mathbf{h}_m(\mathbf{u}, \mathbf{m}) \quad \text{in} \quad L^2(\Omega_T),
\]
where it obviously suffices to show the desired property componentwise. With the definition from (6) and the boundedness of \( \lambda^m \), a direct computation proves
\[
\| \varepsilon^m(\mathbf{m}_{hk}^-) - \varepsilon^m(\mathbf{m}) \|_{L^2(\Omega_T)}^2 \lesssim \| \mathbf{m}_{hk}^- - \mathbf{m} \|_{L^2(\Omega_T)}^2,
\]
cf. [24]. The pointwise convergence of \( \mathbf{m}_{hk}^- \) from (29d) in combination with Lebesgue’s dominated convergence theorem, now yield the strong convergence \( \mathbf{m}_{hk}^- \cdot \zeta \rightarrow \mathbf{m} \cdot \zeta \). For any indices \( i, j, p = 1, 2, 3 \) this shows
\[
((\varepsilon^m(\mathbf{m}_{hk}^-))_{ij}(\mathbf{m}_{hk}^-)_p, \zeta_p) \rightarrow (\varepsilon^m(\mathbf{m})_{ij}\mathbf{m}_p, \zeta_p).
\]

By definition of the magnetostrictive component it therefore only remains to show
\[
(\varepsilon(\mathbf{u}_{hk}^-))_{ij}(\mathbf{m}_{hk}^-)_p \rightharpoonup (\varepsilon(\mathbf{u}))_{ij} \cdot \mathbf{m}_p \quad \text{in} \quad L^2(\Omega_T)
\]
for any combination \( i, j, p = 1, 2, 3 \) of indices. Analogously to above, this can be seen by
\[
((\varepsilon(\mathbf{u}_{hk}^-))_{ij}(\mathbf{m}_{hk}^-)_p, \zeta_p) = (\varepsilon(\mathbf{u}_{hk}^-))_{ij}(\mathbf{m}_{hk}^-)_p \zeta_p \rightarrow (\varepsilon(\mathbf{u}))_{ij} \cdot \mathbf{m}_p \zeta_p = (\varepsilon(\mathbf{u}))_{ij} \mathbf{m}_p \zeta_p).
\]
for all $\zeta \in C^\infty(\Omega_T)$, where the convergence of $\varepsilon(u_{hk}^-)$ towards $\varepsilon(u)$ particularly follows from the convergence of $u_{hk}^-$ towards $u$ in $L^2(H^1)$. So far, we have thus proved
\[
\int_0^T ((\alpha_m + m \times m_t), (m \times \zeta)) = -C_1 \int_0^T (\nabla m, \nabla (m \times \zeta)) + \int_0^T (h_m(u, m), (m \times \zeta)) = \int_0^T (\pi(m), (m \times \zeta)).
\]
Proceeding as in [5], we conclude (11) by use of elementary pointwise calculations. The equality $m(0, \cdot) = m^0$ in the trace sense follows from the weak convergence $m_{hk} \rightharpoonup m$ in $H^1(\Omega_T)$ and thus weak convergence of the traces. The equality $u(0, \cdot) = u^0$ follows analogously.

To prove (12), we argue similarly. From (17), we obtain
\[
\int_0^T ((\dot{u}_{hk}, t), \psi_h) + \int_0^T (\lambda^c \varepsilon(u_{hk}^+), \varepsilon(\psi_h)) = \int_0^T (\lambda^c \varepsilon^m(m_{hk}^+), \varepsilon(\psi_h)).
\]
For the first summand on the left-hand side, we perform integration by parts in time and, due to the shape of $\psi_h$, get
\[
\int_0^T ((\dot{u}_{hk}, t), \psi_h) = -\int_0^T (\dot{u}_{hk}, (\psi_h)_t) + \int_0^T (\dot{u}_{hk}(T, \cdot), \psi_h(T, \cdot)) - (\dot{u}_{hk}(0, \cdot), \psi_h(0, \cdot)).
\]
Passing to the limit $(h, k) \to 0$, we see
\[
\int_0^T ((\dot{u}_{hk}, t), \psi_h) \longrightarrow -\int_0^T (\dot{u}, (\psi)_t) - (\dot{u}(0, \cdot), \psi(0, \cdot)).
\]
Here, we have used the assumed convergence of the initial data. From (29h) and the definition of $\dot{u}_{hk}$, we get $\dot{u}_{hk} = \partial_t u_{hk}$, and therefore, by use of weak lower semi-continuity, conclude
\[
\|\dot{u} - \partial_t u\|_{L^2(\Omega)}^2 \leq \liminf \|\dot{u}_{hk}^- - \partial_t u_{hk}\|_{L^2(\Omega)}^2 = 0
\]
whence $\dot{u} = \partial_t u$ almost everywhere in $\Omega_T$. The convergence of the terms
\[
\int_0^T (\lambda^c \varepsilon(u_{hk}^+), \varepsilon(\psi_h)) \longrightarrow \int_0^T (\lambda^c \varepsilon(u), \varepsilon(\psi)) \quad \text{and}
\]
\[
\int_0^T (\lambda^c \varepsilon^m(m_{hk}^+), \varepsilon(\psi_h)) \longrightarrow \int_0^T (\lambda^c \varepsilon^m(m), \varepsilon(\psi))
\]
is straightforward. In summary, we have thus shown (12).

It remains to show the energy estimate (13). From the discrete energy estimates (25) and (27), in combination with Korn’s inequality, we get for any $t' \in [0, T]$ with $t' \in [t_\ell, t_{\ell+1})$
\[
\|\nabla m_{hk}^+(t')\|_{L^2(\Omega)}^2 + \|v_{hk}(t')\|_{L^2(\Omega)}^2 + \|\nabla u_{hk}^+(t')\|_{L^2(\Omega)}^2 + \|\dot{u}_{hk}^+(t')\|_{L^2(\Omega)}^2
\]
\[
= \|\nabla m_{hk}^+(t')\|_{L^2(\Omega)}^2 + \int_0^{t'} \|v_{hk}(t')\|_{L^2(\Omega)}^2 + \|\nabla u_{hk}^+(t')\|_{L^2(\Omega)}^2 + \|\dot{u}_{hk}^+(t')\|_{L^2(\Omega)}^2
\]
\[
\leq \|\nabla m_{hk}^+(t')\|_{L^2(\Omega)}^2 + \int_0^{t_{\ell+1}} \|v_{hk}(t')\|_{L^2(\Omega)}^2 + \|\nabla u_{hk}^+(t')\|_{L^2(\Omega)}^2 + \|\dot{u}_{hk}^+(t')\|_{L^2(\Omega)}^2
\]
\[
\leq \tilde{C},
\]
for some constant $\tilde{C}$ which is independent of $h$ and $k$. Integration in time thus yields for any measurable set $\mathcal{S} \subseteq [0, T]$

$$\int_{\mathcal{S}} \| \nabla m^+(t') \|_{L^2(\Omega)}^2 + \int_{\mathcal{S}} \| \nabla u^+(t') \|_{L^2(\Omega)}^2 + \int_{\mathcal{S}} \| \nabla \hat{u}^+(t') \|_{L^2(\Omega)}^2 \leq \int_{\mathcal{S}} \tilde{C}. $$

Weak semi-continuity now shows

$$\int_{\mathcal{S}} \| \nabla \mathbf{m} \|^2_{L^2(\Omega)} + \int_{\mathcal{S}} \| \mathbf{m}_\ell \|^2_{L^2(\Omega_t)} + \int_{\mathcal{S}} \| \nabla \mathbf{u} \|^2_{L^2(\Omega)} + \int_{\mathcal{S}} \| \mathbf{u}_\ell \|^2_{L^2(\Omega)} \leq \int_{\mathcal{S}} \tilde{C},$$

which concludes the proof. \hfill \(\Box\)

**Remark.** Finally, we like to comment on the choice of $0 \leq \theta \leq 1/2$ to emphasize how variants of Theorem 4 are read and proved.

1. For $0 \leq \theta < 1/2$, one has to bound the term $k^2 \sum_{\ell=0}^{j-1} \| \nabla v^\ell_h \|_{L^2(\Omega)}^2$ in Corollary 9 in order to prove boundedness of the discrete quantities. This can be achieved by using an inverse estimate $\| \nabla v^\ell_h \|_{L^2(\Omega)}^2 \lesssim \frac{1}{h^2} \| v^\ell_h \|_{L^2(\Omega)}^2$. The latter term can then be absorbed into the term $k \sum_{\ell=0}^{j-1} \| v^\ell_h \|_{L^2(\Omega)}^2$ and thus yields convergence as $\frac{k}{h} \to 0$.

2. For the intermediate case $\theta = \frac{1}{2}$, the limit $k \theta \int_0^T (\nabla v^\ell_h, \nabla (m^\ell_h \times \zeta)) \to 0$ is no longer valid, see [1, Proof of Thm. 2]. As suggested in [1], this can be circumvented by an inverse estimate provided that $\frac{k}{h} \to 0$.

\hfill \(\Box\)

### 6. Numerical Experiments

In this section, we investigate the performance of the proposed Algorithm 2 empirically. We compare Algorithm 2 with the midpoint scheme from [9, 25] for the following blow-up benchmark example in 2D, proposed in [7, 8]: On $\Omega = (-0.5, 0.5)^2$, we solve problem (9). For some fixed parameter $s \in \mathbb{R}$ and $A := (1 - 2|x|)^4/s$, the initial magnetization reads

$$m_0(x) = \begin{cases} 
(0, 0, -1) & \text{for } |x| \geq 0.5 \\
\frac{(2xA^2-|x|^2)}{(A^4+|x|^2)} & \text{for } |x| \leq 0.5.
\end{cases}$$

This choice of $m_0$ is motivated in [8] in order to form some singularity at the center $x = 0$.

The triangulation $\mathcal{T}_r$, used in the numerical simulation is defined through a positive integer $r$ and consists of $2^{2r+1}$ halved squares with edge length $h = 2^{-r}$. Since this triangulation is of Delaunay type, the angle condition (20) is satisfied, see [1]. For the magnetostriction, we took $\lambda^e$ and $\lambda^m$ to be $2 \times 2$ tensors with $\lambda^e = \lambda^e_{1111} = \lambda^e_{2222} = C^e$, $\lambda^m = \lambda^m_{1111} = \lambda^m_{2222} = C^m$, for given constants $C^e, C^m \geq 0$. For comparison, the midpoint scheme is computed as described in [25]. The latter requires a fixed point iteration, where the tolerance is chosen as $\varepsilon = 10^{-10}$, and a time-step $k_m > 0$ that satisfies the associated mesh size condition $k_m \leq C h^2$ from [4, 9, 25]. In our computations for the midpoint scheme, we thus chose $k_m = h^2/10$. The time-step size of Algorithm 2 is denoted by $k_a$ and does not depend on the spatial mesh-size, i.e. as $h$ is decreased, $k_a$ remains fixed throughout the computations while $k_m$ needs to be stepwise decreased. The linear systems of Algorithm 2 are solved using an iterative method, and the constraint on the space $K^2_{m_h}$ is incorporated via the Lagrange multiplier approach from [17, 18].
Table 1. Comparison of CPU and blow-up time $T_B$ for Algorithm 2 and midpoint scheme [9] with $\alpha = 1$, $T=0.3\text{s}$, and $C^e = C^m = 0$.

| $1/h$ | CPU | $T_B$ | CPU | $T_B$ | CPU | $T_B$ | CPU | $T_B$ |
|-------|-----|-------|-----|-------|-----|-------|-----|-------|
| Alg 2 | 47.5 | 0.036 | 29.1 | 0.024 | 25.6 | 0.04 | 141.5 | 0.059 |
| Mid   | 136.5| 0.038 | 126.7| 0.022 | 203.7| 0.032| N.A.N | N.A.N |

Figure 1. $W_{1,\infty}(\Omega)$ semi-norm from Algorithm 2 for different values of $h$, with $C^e = C^m = 0$ $r=5$, $s=4$, $k_a = 10^{-5}$.

In a first experiment, we consider the exchange-only case of LLG and thus neglect magnetostrictive effects as well as all other field contributions, i.e. $\pi(\cdot) = 0$. We compare the two algorithms for $\alpha = 1$, $s = 4$, $\theta = 1$, $k_a = 10^{-5}$, $C^e = C^m = 0$, and $T = 0.3\text{s}$. As initial value for $k_m$, we choose $10^{-5}$. In Table 1, we investigate the overall computation time as well as the empirical blow-up time, which is the time when the $|m(t)|_{1,\infty} = \|\nabla m(t)\|_{L^\infty(\Omega)}$ reaches its maximum. We observe that Algorithm 2 leads to significantly lower computation time than the midpoint scheme. Moreover, the blow-up time seems to vary between the different schemes. We observed that the blow-up times can be brought more in line with each other if the time-step size $k_a$ is a little decreased (not displayed). As expected, in comparison to the midpoint scheme, Algorithm 2 can work with larger time-steps for reasonably small $h$.

On the other hand, the blow-up time seems to increase as $h$ becomes smaller as shown in Figure 1. This effect was not observable in [9] due to the fixed-point iteration and thus the coupling of $h$ and $k_m$. Our empirical observation raises the question of the mere existence
and behaviour of the blow-up time in case of exchange only. Put explicitly, the finite time blow-up might be a numerical artifact stemming from insufficient spatial resolution.

In Figure 2, we plot the discrete energy for the exchange-only case with $C^e = C^m = 0$ defined by $E(m, t) = \frac{1}{2} \| \nabla m(t) \|_{L^2(\Omega)}^2$, and investigate the stability of the respective algorithms when $\alpha$ becomes small. The kinks in the graph coincide with the empirical blow-up times. We observe that both algorithms seem to be stable, while Algorithm 2 provides a stronger energy decay for small values of $\alpha$.

In a second experiment, we include magnetostriction. In Table 2, we compare the two algorithms for $C^e = 40$, $C^m = 10$, and $T = 0.015[s]$ and observe similar results as for the exchange-only case for LLG. Even with included magnetostrictive effects, the blow-up time varies a lot depending on the spatial resolution $h$, as well as between the different schemes. Finally, in the Figures 3 and 4, we compare the computational results of the two different
schemes. Due to the symmetry of the problem, we only show the evolution of the $L^2(\Omega)$-average

$$\|m_j\|_{L^2(\Omega)} = \frac{1}{|\Omega|} \left( \int_{\Omega} m_j^2 \right)^{1/2} = \|m_j\|_{L^2(\Omega)}, \quad j = 1, 3$$

for the $m_1$ and $m_3$ components of the magnetization.

Overall, we conclude that the results of our algorithm are in good agreement with the midpoint scheme, more feasible for small $\alpha$, throughout much faster to compute, and finally easier to implement.
