Fast-Decodable MIDO Codes with Large Coding Gain

K. Pavan Srinath and B. Sundar Rajan, Senior Member, IEEE

Abstract—In this paper, a new method is proposed to obtain full-diversity, rate-2 (rate of 2 complex symbols per channel use) space-time block codes (STBCs) that are full-rate for multiple input, double output (MIDO) systems. Using this method, rate-2 STBCs for $4 \times 2$, $6 \times 2$, $8 \times 2$ and $12 \times 2$ systems are constructed and these STBCs are fast ML-decodable, have large coding gains and STBC-schemes consisting of these STBCs have a non-vanishing determinant (NVD) so that they are DMT-optimal for their respective MIMO systems. It is also shown that the Srinath-Rajan code [R. Vehkalahti, C. Hollanti, and F. Oggier, “Fast-Decodable Asymmetric Space-Time Codes from Division Algebras,” IEEE Trans. Inf. Theory, Apr. 2012] for the $4 \times 2$ system, which has the lowest ML-decoding complexity among known rate-2 STBCs for the $4 \times 2$ MIMO system with a large coding gain for $4/16$-QAM, has the same algebraic structure as the STBC constructed in this paper. This also settles in positive a previous conjecture that the STBC-scheme that is based on the Srinath-Rajan code has the NVD property and hence is DMT-optimal for the $4 \times 2$ system.

Index Terms—Cyclic division algebra (CDA), fast-decodability, Galois group, multiple-input double-output (MIDO) systems, non-vanishing determinant (NVD), space-time block codes (STBCs).

I. INTRODUCTION AND BACKGROUND

Space-time block coding [3] has been continually evolving over the last decade. Beginning with the simple Alamouti code [4] for 2 transmit antennas, the evolution of space-time coding theory has resulted in the development of sophisticated full-diversity codes from cyclic division algebras (CDAs) [5]-[9] for any number of transmit antennas. At one end are the rate-1 (see Definition 2) STBCs that are multi-group decodable (see, for example, [10]-[13] for a definition of multi-group decodable STBCs) and have a relatively low maximum likelihood (ML)-decoding complexity while at the other end are rate-$n_t$ (for $n_t$ transmit antennas) full-diversity STBCs obtained from CDAs which have a very high ML-decoding complexity. The usage of powerful tools from number theory has resulted in rate-$n_t$ (for $n_t$ transmit antennas) STBCs with high coding gains, and STBC-schemes (see Definition 5) employing these codes have a non-vanishing determinant (see Definition 6) so that they are diversity-multiplexing gain tradeoff (DMT)-optimal [8] for any number of receive antennas. Examples of such codes are the perfect codes [7], [9].

Recent interest has been towards asymmetric MIMO systems where the number of receive antennas $n_r$ is less than the number of transmit antennas $n_t$. Such a scenario occurs, for example, in the downlink transmission from a base station to a mobile phone, and in digital video broadcasting (DVB) where communication is between a TV broadcasting station and a portable TV device (see, for example, [14]). Of particular interest is the $4 \times 2$ MIMO system for which a slew of rate-2 STBCs have been developed [1], [2], [15]-[20], with the particular aim of allowing fast-decodability (see Definition 7), a term that was first coined in [15]. Among these codes, those in [1], [16]-[20] have been shown to have a minimum determinant that is bounded away from zero irrespective of the size of the signal constellation and hence STBC-schemes that consist of these codes have the NVD property and are DMT-optimal for the $4 \times 2$ MIMO system [21]. A generalization of fast-decodable STBC construction for higher number of transmit antennas has been proposed in [1]. STBCs from nonassociative division algebras have also been proposed in [22].

The best performing code for the $4 \times 2$ MIMO system is the Srinath-Rajan code [2] which has the least ML-decoding complexity (of the order of $M^{4.5}$ for a square $M$-QAM) among comparable codes and the best known normalized minimum determinant (see Definition 4) for 4/16-QAM. However, this code was constructed using an ad hoc technique and had not been proven to have a non-vanishing determinant for arbitrary QAM constellations. In this paper, we propose a novel construction scheme to obtain rate-2 STBCs which have full-diversity, and STBC-schemes that employ these codes have the NVD property. We then explicitly construct such STBCs for $n_t \times 2$ MIMO systems, $n_t = 4, 6, 8, 12$, and these codes are fast-decodable and have large normalized minimum determinants.

A. Contributions and paper organization

The contributions of this paper may be summarized as follows.

1) We propose a novel algebraic method to construct rate-2 STBCs with full-diversity. A highlight of our mathematical framework is that it is a generalization of the frameworks of [20] and [22].

2) Using our construction methodology, we construct rate-2, fast-decodable STBCs for $4 \times 2$, $6 \times 2$, $8 \times 2$ and
12 × 2 MIDO systems. All these four STBCs have large normalized minimum determinants and fast-decodability (see Table I). In addition, STBC-schemes that consist of these STBCs have the NVD property making them DMT-optimal for their respective MIDO systems.

3) We show that the Srinath-Rajan (SR) code [2] has the same underlying algebraic structure as the STBC constructed in this paper for the 4 × 2 system. This way, we prove the conjecture that the STBC-scheme based on the SR-code has the NVD property [1]. It is to be noted that A4 with a change of basis, while having lower ML-decoding complexity than A4, has a smaller minimum determinant [1, Sec. VIII-A].

These STBCs are not available explicitly in [1]. However, it is possible to construct such STBCs with the ML-decoding complexities shown in corresponding row.

### Table I

| # Tx antennas | STBC S | Constellation (average energy $E$) | $\delta_{\text{min}}(S)$ | ML-decoding complexity (Worst case) |
|---------------|--------|-----------------------------------|--------------------------|-----------------------------------|
| 4             | $S_{4 \times 2}$ | QAM | $\frac{1}{25E^4}$ | $O(M^{4.5})$ |
|               | Punctured perfect code [7] | QAM | $\frac{1}{15E^4}$ | $O(M^{5.5})$ |
|               | $C_1$ [1, Sec. VIII-B], [17] | QAM | $\frac{1}{25E^4}$ | $O(M^{6.5})$ |
|               | $A_4$ [1, Sec. VIII-A] | QAM | Not available$^e$ | $O(M^{5.5})$ |
|               | $A_4$ (Change of Basis) [1, Sec. VIII-A] | QAM | Not available$^e$ | $O(M^{4.5})$ |
|               | Punctured $C_4$ [35] | QAM | $\frac{1}{16E^4}$ | $O(M^{7})$ |
| 6             | $S_{6 \times 2}$ | HEX | $\frac{1}{25E^6}$ | $O(M^{8.5})$ |
|               | Punctured perfect code [7] | HEX | $\frac{1}{25E^6}$ | $O(M^{11.5})$ |
|               | Punctured $C_6$ [35] | HEX | $\frac{1}{25E^6}$ | $O(M^{11.5})$ |
|               | VHO-Code [1, Sec. X-C] | QAM | Not available$^e$ | $O(M^{8.5})$ |
|               | VHO-Code (Change of Basis) | QAM | Not available$^e$ | $O(M^{7})$ |
| 8             | $S_{8 \times 2}$ | QAM | $\frac{1}{25(15)^2E^9}$ | $O(M^{9.5})$ |
|               | Punctured perfect code [9] | QAM | $\frac{1}{5(12)^2E^9}$ | $O(M^{15.5})$ |
|               | VHO-Code [1] | QAM | Not Available$^e$ | $O(M^{9.5})$ |
| 12            | VHO-Code [1] | QAM | Not Available$^e$ | $O(M^{14.5})$ |
|               | $S_{12 \times 2}$ | HEX | $\delta_{\text{min}} \geq \frac{1}{(14E)^{17}}$ | $O(M^{17.5})$ |

$^e$ Punctured STBCs for $n_r < n_t$ refer to rate-$n_r$ STBCs obtained from rate-$n_t$ STBCs (which transmit $n_t^2$ complex information symbols in $n_t$ channel uses) by restricting the number of complex information symbols transmitted to be only $n_t n_r$.

$^f$ The exact minimum determinants of these STBCs have not been calculated, but it has been shown that these STBCs have the NVD property [1]. It is to be noted that $A_4$ with a change of basis, while having lower ML-decoding complexity than $A_4$, has a smaller minimum determinant [1, Sec. VIII-A].

$^g$ These STBCs are not available explicitly in [1]. However, it is possible to construct such STBCs with the ML-decoding complexities shown in corresponding row.

The paper is organized as follows. Section II gives the system model, relevant definitions and a brief overview of CDAs. Section III builds the theory needed to obtain rate-2 STBCs, while Section IV deals with the construction of fast-decodable STBCs for $4 \times 2$, $6 \times 2$, $8 \times 2$ and $12 \times 2$ systems. The property of the constructed STBCs that allows fast-decodability is explained in Section V, and simulation results are given in Section VI. Concluding remarks constitute Section VII.

### Notation

Throughout the paper, the following notation is employed.

- **Bold, lowercase letters** denote vectors, and **bold, uppercase letters** denote matrices.
- **$X^H$, $X^T$**, $\text{det}(X)$, $\text{tr}(X)$ and $||X||$ denote the conjugate transpose, the transpose, the determinant, the trace and the Frobenius norm of $X$, respectively.
- **$\text{diag}(A_1, A_2, \cdots, A_n)$** denotes a block diagonal matrix with matrices $A_1$, $A_2$, $\cdots$, $A_n$ on its main diagonal blocks.
- **The real and the imaginary parts of a complex-valued vector $x$** are denoted by $\text{Re}(x)$ and $\text{Im}(x)$, respectively.
\[ |S| \text{ denotes the cardinality of the set } S, \text{ and for a set } T \text{ such that } |T \cap S| \neq 0, S \setminus T \text{ denotes the set of elements of } S \text{ not in } T. \]

- \( I \) and \( O \) denote the identity and the null matrix of appropriate dimensions.
- \( \mathbb{E}(X) \) denotes the expectation of the random variable \( X \).
- \( \mathbb{R}, \mathbb{C} \) and \( \mathbb{Q} \) denote the field of real, complex and rational numbers, respectively, and \( Z \) denotes the ring of rational integers.
- Unless used as an index, a subscript or a superscript, \( i \) denotes \( \sqrt{-1} \) and \( \omega \) denotes the primitive third root of unity.
- For fields \( K \) and \( F, K/F \) denotes that \( K \) is an extension of \( F \) (hence, \( K \) is an algebra over \( F \)) and \( [K : F] = m \) indicates that \( K \) is a finite extension of \( F \) of degree \( m \).
- \( M_n(K) \) denotes the ring of \( n \times n \) sized matrices with entries from a field \( K \).
- \( \text{Gal}(K/F) \) denotes the Galois group of \( K/F \), i.e., the group of \( F \)-linear automorphisms of \( K \). If \( \sigma \) is any \( F \)-linear automorphism of \( K \), \( (\sigma) \) denotes the cyclic group generated by \( \sigma \).
- The elements 1 and 0 are understood to be the multiplicative identity and the additive identity, respectively, of the unit ring \( R \) in context.
- \( \text{im}(\Phi) \) denotes the image of the map \( \Phi \).

II. SYSTEM MODEL AND DEFINITIONS

We consider an \( n_t \) transmit antenna, \( n_r \) receive antenna MIMO system \((n_t \times n_r)\) system with perfect channel-state information available at the receiver (CSIR) alone. The channel is assumed to be quasi-static with Rayleigh fading. The system model is

\[
Y = \sqrt{\rho}HS + N, \tag{1}
\]

where \( Y \in \mathbb{C}^{n_r \times T} \) is the received signal matrix, \( S \in \mathbb{C}^{n_t \times T} \) is the codeword matrix that is transmitted over a block of \( T \) channel uses, \( H \in \mathbb{C}^{n_r \times n_t} \) and \( N \in \mathbb{C}^{n_r \times T} \) are respectively the channel matrix and the noise matrix with entries independently and identically distributed (i.i.d.) circularly symmetric complex Gaussian random variables with zero mean and unit variance. The average signal-to-noise ratio (SNR) at each receive antenna is denoted by \( \rho \). It follows that

\[
\mathbb{E}(\|S\|^2) = T. \tag{2}
\]

A space-time block code (STBC) \( S \) is block-length \( T \) for an \( n_t \) transmit antenna MIMO system is a finite set of complex matrices of size \( n_t \times T \). Throughout the paper, we consider linear STBCs [24] encoding symbols from a complex constellation \( \mathcal{A}_q \) which is QAM or HEX. An \( M \)-PAM, \( M \)-QAM and \( M \)-HEX constellation, with \( M = 2^a \), \( a \) even and positive, are respectively given as

\[
M\text{-PAM} = \{-M + 1, -M + 3, -M + 5, \ldots, M - 1\},
\]

\[
M\text{-QAM} = \{a + ib, a, b \in \sqrt{M}\text{-PAM}\},
\]

\[
M\text{-HEX} = \{a + \omega b, a, b \in \sqrt{M}\text{-PAM}\}.
\]

Assuming that \( \mathcal{A}_q \) is \( M \)-QAM or \( M \)-HEX, the symbols \( s_i \) encoded by the STBC are of the form \( s_i = \bar{s}_i + \beta s_i \), with \( \bar{s}_i, s_i \in \sqrt{M}\text{-PAM} \) and \( \beta = i \) or \( \omega \) depending on whether \( \mathcal{A}_q \) is \( M \)-QAM or \( M \)-HEX, respectively. Therefore, the STBC \( S \) is of the form

\[
S = \left\{ S_i = \sum_{j=1}^{k} (\bar{s}_{ij}\bar{A}_j + s_{ij}\bar{A}_j) \mid s_{ij} \in \mathcal{A}_q \right\} \tag{3}
\]

where \( S_i, i = 1, 2, \ldots, |\mathcal{A}_q|^k \), are the codeword matrices, and \( \bar{A}_j \) and \( \bar{A}_j \) are complex weight matrices of the STBC. We assume that the average energy of \( \mathcal{A}_q \) is \( E_i \) units. Noting the symmetry of both \( M \)-QAM and \( M \)-HEX, we have \( \mathbb{E}(\|s_{ij}\|^2) = |\mathcal{A}_q|/2, \mathbb{E}(\bar{s}_{ij}s_{ij}) = 0 \). So, the energy constraint in (2) translates to \( E \sum_{i=1}^{k} \text{tr} (\bar{A}^H\bar{A} + \bar{A}\bar{A}^H) = 2T \).

**Definition 1:** (Generator matrix) An STBC of the form

\[
S = \left\{ S_i = \sum_{j=1}^{k} (\bar{s}_{ij}\bar{A}_j + s_{ij}\bar{A}_j) \mid s_{ij}, \bar{s}_{ij} \in \text{PAM} \right\},
\]

is said to be a space-time lattice code [1], and its generator matrix \( G \) is given as

\[
G = \left[ \text{vec}(\bar{A}_1) \text{ vec}(\bar{A}_1) \cdots \text{vec}(\bar{A}_k) \text{ vec}(\bar{A}_k) \right],
\]

where for a matrix \( X = [x_1, x_2, \ldots, x_m] \) with \( x_i \) being column vectors, \( \text{vec}(X) \triangleq [x_1^T, x_2^T, \ldots, x_m^T]^T \), and for a complex column vector \( x = [x_1, x_2, \ldots, x_n]^T \), \( \mathbb{E}(\|x\|^2) = [\text{Re}(x_1), \text{Im}(x_1), \ldots, \text{Re}(x_n), \text{Im}(x_n)]^T \).

**Definition 2:** (STBC Rate) The rate of an STBC is \( \frac{\text{Rank}(G)}{2T} \) complex symbols per channel use, where \( G \) is the generator matrix of the STBC. The STBC is said to encode \( \frac{\text{Rank}(G)}{2} \) independent complex symbols.

An STBC having a rate of \( \min(n_t, n_r) \) complex symbols per channel use is said to be a full-rate STBC.

**Definition 3:** (Cubic Shaping) If the generator matrix \( G \) has column orthogonality, the space-time lattice code is said to have cubic shaping [1].

Among STBCs transmitting at the same rate in bits per channel use (the bit rate of \( S \) is \( \log_2(|\mathcal{A}_q|^k) \) bits per channel use), the metric for comparison that decides their error performance is the normalized minimum determinant which is defined as follows.

**Definition 4:** (Normalized minimum determinant) For an STBC \( S = \{S_i, i = 1, \ldots, |S|\} \) that satisfies (2), the normalized minimum determinant \( \delta_{\text{min}}(S) \) is defined as

\[
\delta_{\text{min}}(S) = \min_{S_i, S_j \in S, i \neq j} \|\text{det}(S_i - S_j)\|^2. \tag{4}
\]

For full-diversity STBCs, \( \delta_{\text{min}}(S) \) defines the coding gain [3], with the coding gain given by \( \delta_{\text{min}}(S)^{1/2} \). Between two competing STBCs, the one with the larger normalized minimum determinant is expected to have a better error performance.

**Note 1:** When the average energy of transmission in each time slot is uniform, then the energy constraint given by (2) implies that \( \mathbb{E}(\|s_i\|^2) = 1, \forall i = 1, \ldots, T \), where \( s_i \) denotes the \( i \text{th} \) column of a codeword matrix.

**Definition 5:** (STBC-scheme [23]) An STBC-scheme
$x_{\text{scheme}}$ is defined as a family of STBCs indexed by $\rho$, each STBC of block length $T$ so that $x_{\text{scheme}} = \{S(\rho)\}$, where the STBC $S(\rho)$ corresponds to an average signal-to-noise ratio of $\rho$ at each receive antenna.

For STBC-schemes that consist of linear STBCs employing complex lattice constellations, the weight matrices define the STBC-scheme. The weight matrices are fixed and the size and average energy of the signal constellation are allowed to vary in accordance with $\rho$. Associated with such linear STBC-schemes is the notion of non-vanishing determinant (NVD).

Definition 6: (Non-vanishing determinant) [6] A linear STBC-scheme $x_{\text{scheme}}$, whose STBCs are defined by weight matrices $\{A_i, A_i, i = 1, \cdots, k\}$ and employ complex constellations that are finite subsets of an infinite complex lattice $A_L$, is said to have the non-vanishing determinant (NVD) property if $S_{\infty} = \sum_{i=1}^{n-k} (s_i A_i + s_i A_Q)$ is such that

$$\inf_{S \in S_{\infty}} |\det(S)|^2 > 0.$$ 

With respect to ML-decoding, if the STBC transmits $k$ complex symbols in $T$ channel uses where the symbols are encoded from a suitable complex constellation of size $M$, an exhaustive search requires performing $O(M^k)$ operations ($O()$ stands for “big $O$ of”) because the $k$ symbols have to be jointly evaluated. However, some STBCs allow fast-decodability which is defined as follows.

Definition 7: (Fast-decodable STBC) [15] Consider an STBC encoding $k$ complex information symbols from a complex constellation of size $M$. If the ML-decoding of this STBC by an exhaustive search involves performing only $O(M^p)$ computations, $p < k$, the STBC is said to be fast-decodable.

For more on fast-decodability, one can refer to [2], [15].

A. Cyclic Division Algebras

A cyclic division algebra (CDA) $A$ of degree $n$ over a number field $F$ is a vector space over $F$ of dimension $n^2$. The centre of $A$, denoted by $Z(A)$ and defined as

$$Z(A) = \{A \in A \mid AB = BA, \forall B \in A\},$$

is the field $F$ itself, and there exists a maximal subfield $K$ of $A$ such that $K$ is a Galois extension of degree $n$ over $F$ with a cyclic Galois group generated by a cyclic generator $\tau$. $A$ is a right vector space over $K$ and can be expressed as $A = K + i K + i^2 K + \cdots + i^{n-1} K$, where $\omega = i(a), \forall a \in A$, $i^a = \gamma$ for some $\gamma \in F^\times = F \setminus \{0\}$ such that the norm $N_{K/F}(a) = \prod_{i=0}^{n-1} \tau(a)$ of any element $a \in K$ satisfies [28, Proposition 2.4.5]

$$N_{K/F}(a) = \gamma^p$$

for any divisor (in $Z$) $p$ of $n$ with $1 \leq p < n$. The CDA $A$ is denoted by $(K/F, \tau, \gamma)$. $A$ has a matrix representation in $M_n(K)$. This means that there exists an injective ring homomorphism from $A$ to the matrix ring $M_n(K)$, described as follows. The map

$$\lambda_a : d \rightarrow ad, \quad \forall a \in A,$$
the vector $D_i = [a_i, \tau(a_i), \ldots, \tau^{n-1}(a_i)]^T$, $i = 0, \ldots, n-1$, where
$$D_i = \text{diag}[1, \ldots, 1, \gamma, \ldots, \gamma],$$
with $\gamma$ scaled unitary, i.e., $\gamma = \frac{1}{\sqrt{n}}$ for some $\lambda \in \mathbb{R}$ (the scalar $1/\sqrt{n}$ is the normalizing factor for $\mathbf{R}$ to ensure that the energy constraint is satisfied). Further $\gamma$ is generally chosen such that $|\gamma|^2 = 1$. The perfect codes, which employ these techniques, have among the largest known coding gains in their comparable class.

Note 2: In literature, certain spherically-shaped codes built from non-orthogonal maximal orders [29]-[31] and shaping lattices [32] have larger coding gains than the perfect codes. Notably, the Golden+ code [29], a spherically-shaped STBC, has better coding gain than the well-known Golden code for 2 transmit antennas which is a linear STBC with cubic shaping. The decoding of spherically-shaped STBCs can be performed either by a modified sphere-decoder [33] or by employing sphere-encoding together with MMSE-GDFE [32] which also effectively results in ML performance.

III. MATHEMATICAL FRAMEWORK
Let $F$ and $L$ be two distinct number fields and $K$ a Galois extension of both $F$ and $L$ such that
1) $Gal(K/F) = \langle \sigma \rangle$ with $|Gal(K/F)| = m$,
2) $Gal(K/L) = \langle \tau \rangle$ with $|Gal(K/L)| = n$,
3) $\sigma$ and $\tau$ commute, i.e., $\sigma(a) = \tau(a)$, $\forall a \in K$.

Let $A = (K/F, \sigma, \gamma)$ be a cyclic division algebra of degree $m$ over $F$ with $\{1, j, j^2, \ldots, j^{m-1}\}$ being its basis as an $m$-dimensional right vector space over $K$.

We consider a non-commutative ring $\mathcal{M}_A$ which is an $n$-dimensional bimodule over $A$ (i.e., both a left $A$-module and a right $A$-module), but we treat $\mathcal{M}_A$ as a right $A$-module in this paper. The structure of $\mathcal{M}_A$ is as follows. We denote the elements of the basis of $\mathcal{M}_A$ over $A$ by $1, i, i^2, \ldots, i^{n-1}$. The elements of $\mathcal{M}_A$ are of the form $A_0 + iA_1 + \cdots + i^{n-1}A_{n-1}$ with $A_i \in A$ and
$$A_i = i\Upsilon(A), \quad A_0 \in A, \quad i^n = \gamma_m, \quad \text{for some } \gamma_m \in A \quad (9)$$
now, forcing the relation $i^n = i^{a+b}$ for positive integral values of $a$ and $b$, (10) implies that $\gamma_m = i^{\gamma_m}$ so that $\gamma_m$ is invariant under $\Upsilon$. Hence, we require $\gamma_m$ to be of the form $a_0 + j_a + \cdots + j^{m-1}a_{m-1}$, $a_i \in L$, $i = 0, 1, \ldots, m-1$. In this paper, we only consider the case where $\gamma_m \in L \subset K$.

Example 1: Consider $A$ to be $(\mathbb{Q}(i), \sqrt{2})/\mathbb{Q}(\sqrt{2})$, $\sigma : i \rightarrow -i, -1$ which is known to be a division algebra and is a subalgebra of Hamilton’s quaternions. Next consider the Galois extension $(\mathbb{Q}(i), \sqrt{2})/(\mathbb{Q}(i))$ whose Galois group is $\{1, \tau\}$ with $\tau : \sqrt{2} \rightarrow -\sqrt{2}$. Now, $\mathcal{M}_A = \{A_0 + iA_1 | A_0, A_1 \in A, i^2 = i\}$. If $A = a_0 + \sqrt{2}a_1 + i(a_2 + \sqrt{2}a_3) + j(b_0 + \sqrt{2}b_1 + i(b_2 + \sqrt{2}b_3))$, with $a_i, b_j \in \mathbb{Q}$, then $\Upsilon(A) = a_0 - \sqrt{2}a_1 + i(a_2 - \sqrt{2}a_3) + j(b_0 - \sqrt{2}b_1 + i(b_2 - \sqrt{2}b_3))$.

In $\mathcal{M}_A$, we seek conditions under which every element of the form $A_0 + iA_1$ has a unique right inverse, i.e., for every element of the form $A_0 + iA_1$, $A_0, A_1 \in A$, there exists a unique element $B \in \mathcal{M}_A$ such that $(A_0 + iA_1)B = 1$. Towards this end, we make use of the following lemma.

Lemma 1: A nonzero element $A$ of $\mathcal{M}_A$, when it has a right inverse, has a unique right inverse if and only if there exists a unique nonzero element $B \in \mathcal{M}_A$ such that $AB = 0$.

Proof: If $A$ is not a left zero divisor, the uniqueness of the inverse follows, for if $AB = 1$ and $AB' = 1$, then $A(B = B') = 0 \Rightarrow B = B'$. Conversely, if $A$ has a unique right inverse, it is not a left zero divisor, for if $AB = 1$ and $AC = 0$ for some $C \in A$, then $A(B = C) = 1 \Rightarrow C = 0$.

In the following theorem which is a generalization of [20, Theorem 1], we establish conditions under which each element of $\mathcal{M}_A$ of the form $A_0 + iA_1$, $A_0, A_1 \in A$, has a unique right inverse.

Theorem 1: Every nonzero element of $\mathcal{M}_A$ of the form $A_0 + iA_1$, $A_0, A_1 \in A$, has a unique right inverse if and only if
$$\Upsilon(C)\Upsilon^2(C) \cdots \Upsilon^{n-1}(C) \neq \gamma_m, \text{ for every } C \in A. \quad (13)$$

The proof of Theorem 1 is given in Appendix A.

Case 1: The condition in (13) is also necessary and sufficient for any element of the form $i^kA_0 + iA_1$, $A_0, A_1 \in A$, $0 \leq k < i \leq n-1$, to have a unique right inverse. The proof is on similar lines to the proof of Theorem 1.

It is to be noted from (9) that $ij = ji$. So, we have the following possibilities for $\gamma_m$ and $\gamma$ (recall that $\gamma = j^m \in F^m \cap L$).

Remark 1: $\gamma_m \in L \cap F$. In this case $\mathcal{M}_A$ is an associative algebra over $L \cap F$.

Remark 2: $\gamma_m \in L \setminus F$. In this case, $\mathcal{M}_A$ is never an associative algebra over $L \cap F$ and hence does not have a matrix representation, for if $\mathcal{M}_A$ is an associative algebra over $L \cap F$ with $\gamma_m \notin L \cap F$, then we have $ji^k = i^kji$ due to commutativity of $i$ and $j$, but $(ji)^{n-1} = j(i^{n-1}) = ji^n = j\gamma_m \neq \gamma_m j = ji$, leading to a contradiction.

In this paper, we consider the case $\gamma_m \in L \cap F, \gamma \in L \cap F$. Even though $\mathcal{M}_A$ is now nonassociative and does not have a matrix representation, we still can make use of Theorem 1 to obtain invertible matrices, which are desirable from the point of view of constructing full-diversity STBCs. In this direction, we arrive at the following result.
Lemma 2: If every element \( C \) of a cyclic division algebra \( A \) of degree \( n \) is such that \( CY(C) \gamma^2(C) \cdots \gamma^{n-1}(C) \neq \gamma_M \) where \( \gamma_M \) is some nonzero field element of \( A \), then the matrix \( CY(C) \gamma^2(C) \cdots \gamma^{n-1}(C) - \gamma_M I \) is invertible, where \( C, \gamma^2(C), \cdots, \gamma^{n-2}(C) \) and \( \gamma^{n-1}(C) \in K^{m \times m} \) are respectively the matrix representations of \( C, \gamma(C), \cdots, \gamma^{n-2}(C) \) and \( \gamma^{n-1}(C) \) in \( M_m(K) \).

The proof of Lemma 2 is given in Appendix B. We make use of Lemma 2 to obtain the following result.

Theorem 2: Let \( M_A \) be such that any element of the form \( A_0 + iA_1 \) has a unique right inverse, and let \( A_0 \) and \( A_1 \) be matrix representations of \( A_0 \) and \( A_1 \), respectively, in \( M_m(K) \). Consider the matrix

\[
M = \begin{bmatrix}
A_0 & O & \cdots & \gamma_M \gamma^{n-1}(A_1) \\
A_1 & \gamma(A_0) & \cdots & O \\
O & \gamma(A_1) & \cdots & O \\
O & O & \cdots & O \\
\vdots & \vdots & \ddots & \vdots \\
O & O & \cdots & \gamma^{n-1}(A_0)
\end{bmatrix}
\]  

(14)

Then,

1) \( M \) is invertible.
2) \( \det(M) \in L \).

The proof of Theorem 2 is given in Appendix C.

Corollary 1: If all the elements of \( M \) are from \( \mathcal{O}_K \), the ring of integers of \( K \), then \( \det(M) \in L \cap \mathcal{O}_K = \mathcal{O}_L \).

A. Special Case: \( n = 2 \)

For the case where \( n = 2 \) so that \( M_A = \{ A_0 + iA_1 \mid A_0, A_1 \in A \} \), when \( CY(C) \neq \gamma_M, \forall C \in A \), from Theorem 1, there are no left zero divisors in \( M_A \). It follows that there do not exist any right zero divisors in \( M_A \). So, there are no zero divisors in \( M_A \), i.e., if \( AB = 0 \) for \( A, B \in M_A \), then either \( A = 0 \) or \( B = 0 \). It is well known that a nonassociative algebra is division if and only if it contains no zero divisors [34, Page 15-16]. So, \( M_A \) is a nonassociative division algebra. However, the map

\[
\Phi: M_A \rightarrow M_{2m}(K)
\]

\[
A_0 + iA_1 \mapsto \begin{bmatrix} A_0 & \gamma_M \gamma^{n-1}(A_1) \\ A_1 & \gamma^{n-1}(A_0) \end{bmatrix}
\]

is not to be confused to be an injective homomorphism, even though \( \text{im}(\Phi) \) excepting the zero matrix consists of invertible matrices. This is because \( M_A \) is not an associative algebra. However, it is natural to wonder whether \( \text{im}(\Phi) \) is obtained as a matrix representation of some associative division algebra. We establish as follows that this is not the case.

Firstly, \( \text{im}(\Phi) \) is not an algebra since it is not closed under multiplication. To see this, let \( A, B, C, D \) be matrix representations (in \( M_{m}(K) \)) of elements \( A, B, C, D \in A \).

Then,

\[
\begin{bmatrix} A & \gamma_M \gamma^{n-1}(B) \\ B & \gamma^{n-1}(C) \end{bmatrix} = \begin{bmatrix} AC + \gamma_M \gamma^{n-1}(BD) \\ BC + \gamma^{n-1}(TA)D \end{bmatrix}
\]

which does not belong to \( \text{im}(\Phi) \) since \( \gamma_M I \) is not the matrix representation (in \( M_m(K) \)) of \( \gamma_M \) as an element of \( A \). The matrix representation of \( \gamma_M \) in \( M_m(K) \) is \( \Gamma_M = \text{diag}([\gamma_M, \sigma(\gamma_M), \cdots, \sigma^{m-1}(\gamma_M)]) \neq \gamma_M I \) since \( \gamma_M \notin F \).

Secondly, \( \text{im}(\Phi) \) is not a subset of some division algebra. To see this, let

\[
E = \begin{bmatrix} O & \gamma_M I \\ I & O \end{bmatrix}, \quad F = \begin{bmatrix} \Gamma_M & O \\ O & \Gamma_M \end{bmatrix}
\]

where \( \Gamma_M \) is the matrix representation of \( \gamma_M \) in \( M_m(K) \).

Clearly, \( E, F \in \text{im}(\Phi) \), but \( E^2 - F \) is nonzero and singular, and so \( \text{im}(\Phi) \) cannot be a subset of a division algebra.

Note 3: While \( \text{im}(\Phi) \) is not obtained as a matrix representation or a subset of some division algebra, there is still a possibility that it can be obtained as a representation or a subset of some central simple (not necessarily division) algebra.

The mathematical frameworks considered in [20] and [22] to obtain full-diversity STBCs are special cases of our framework, and are briefly described in the following subsections.

B. The full-diversity STBC construction technique of [20]

In [20], a CDA \( A = (K/F, \sigma, \gamma) \) (\( m \) even), an Galois \( L \)-automorphism \( \tau \) such that \( \tau^2 = 1 \), (with the possibility of \( \tau \) belonging to \( \langle \sigma \rangle \)), and an element \( \gamma_M \in F \) such that \( \tau(\gamma_M) = \gamma_M, \forall A \in A \) (as defined in (11)), are used to obtain full-diversity STBCs with fast-decodability for \( 2m \times 2 \) MISO systems. The STBCs are obtained using the following map

\[
\Phi_{\gamma_M}: A \times A \rightarrow M_{2m}(K)
\]

\[
(A, B) \mapsto \begin{bmatrix} A & \gamma_M T(B) \\ B & \gamma(B) \end{bmatrix}
\]

where \( A \) and \( B \) are matrix representations of \( A \) and \( B \) in \( M_{m}(K) \). The difference between this method and our method is in the choice of \( \gamma_M \) which for our case does not belong to \( F \). Though not explicitly mentioned in [20], \( M_A = \{ A + iB \mid A, B \in A \} \), with all the rules of multiplication as specified in the beginning of this section, is an associative division algebra since it contains no zero divisors. The centre \( Z(M_A) \) and maximal subfield \( M \) of \( M_A \) are as follows.

1) When \( \tau \in \langle \sigma \rangle \), \( Z(M_A) = \{ a + i\sqrt{-1}b \mid a, b \in F \} \) and is isomorphic to \( F(\sqrt{-1}) \), while \( M = \{ a + i\sqrt{-1}b \mid a, b \in K \} \) and is isomorphic to \( K(\sqrt{-1}) \).

2) When \( \tau \notin \langle \sigma \rangle \), \( Z(M_A) = F \cap L \) and \( M = K \) in which case, \( M_A \) is a crossed product division algebra of degree \( 2m \) over \( F \cap L \).

---

1Throughout the paper we denote by \( Y(C) \) the matrix obtained by applying \( \tau \) to each entry of \( C \), and for the special case of \( C \) being the matrix representation of \( C \in A \), \( Y(C) \) happens to be the matrix representation of \( Y(C) \).
∀L and its quadratic extension to obtain rate-2 STBCs for 2 transmit antennas and rate-1 words of an STBC for A. General design procedure contradicting the fact that is nonassociative (When \( \gamma \)) is chosen to be either \( \gamma = 1 \) but \( \sigma \) and \( \tau \) commute. 

d) \( \gamma \in F \cap L \).

c) \( \gamma \in K \setminus L \).

e) \( \prod_{i=0}^{2n-1} \Psi^i(C) \neq \gamma_M, \forall C \in A. \)

C. The full-diversity STBC construction technique of [22]

In [22], nonassociative quaternion division algebras are used to obtain rate-2 STBCs for 2 transmit antennas and rate-1 STBCs for 4 transmit antennas. The required nonassociative quaternion division algebra is constructed using a number field \( L \) and its quadratic extension \( K \) with \( \text{Gal}(K/L) = \{1, \tau\} \). The algebra is given as \( \{a + ib \mid a, b \in K, i^2 = \gamma_M \in K \setminus L\} \), and is denoted by \( \text{Cay}(K, \gamma_M) \). Since \( \gamma_M \notin L \), \( \text{Cay}(K, \gamma_M) \) is nonassociative (When \( \gamma_M \in L \), the algebra is an associative quaternion algebra). Note that this is a special case of our proposed method, with \( n = 2, m = 1, A = K \), with the only difference being that \( \gamma_M \in K \setminus L \). Such a case is also included in our framework (see (10)), but the resulting algebra is clearly also not power associative since \( i^2 = \gamma_M, i \neq \gamma_M^2 = i^2 \). A nonassociative algebra is division if and only if it has no zero divisors [34]. It is easy to see that \( \text{Cay}(K, \gamma_M) \) is a division algebra for if it were not, it would contain zero divisors so that \( a\tau(a) = \gamma_M \) for some \( a \in K \) but \( \gamma_M \in K \setminus F \) and \( a\tau(a) \in L \), contradicting the fact that \( a\tau(a) = \gamma_M \). The invertibility of the obtained matrices (nonzero) which are of the form in (14) with \( n = 2, m = 1 \), follows from Theorem 2.

IV. STBC CONSTRUCTION

A. General design procedure

The general scheme to obtain invertible matrices as codewords of an STBC for \( nm \) transmit antennas is as follows.

1) \( L \) is chosen to be either \( \mathbb{Q}(i) \) or \( \mathbb{Q}(\omega) \), the reason being that a finite subset of \( \mathbb{Z}[i] \) is the QAM constellation and that of \( \mathbb{Z}[\omega] \) is the HEX constellation, both of practical significance.

2) A cyclic division algebra \( A = (K/F, \sigma, \gamma) \) of degree \( n \) over a number field \( F \) with \( F \neq L \), and an element \( \gamma_M \) are chosen such that

- \( K/L \) is a Galois extension of degree \( n \) with \( \text{Gal}(K/L) = \{1, \tau\} \).
- \( \sigma \) and \( \tau \) commute.
- \( \gamma \in F \cap L \).
- \( \gamma_M \in L \setminus F \).
- \( \prod_{i=0}^{2n-1} \Psi^i(C) \neq \gamma_M, \forall C \in A \).

When \( A \) satisfies the above conditions, any nonzero matrix having the structure shown in (14) is invertible, with \( A_0 \) and \( A_1 \) being matrix representations (in \( M_n(K) \)) of elements \( A_0 \) and \( A_1 \) of \( A \). If \( A \) is of degree \( m \) over \( F \) so that \( [K : F] = m \), then \( A_0, A_1 \in K^{m \times m} \) and so, \( M \in K^{nm \times nm} \). Each entry of \( A_0 \) and \( A_1 \) which belongs to \( K \) can be viewed as a linear combination of \( n \) independent elements over \( L \) (since \( [K : L] = n \)). We express each element of \( A_0 \) and \( A_1 \) as a linear combination of some chosen \( L \)-basis \( \{\theta_i, i = 1, \ldots, nm| \theta_i \in O_K \} \) over \( O_L \). From the point of view of space-time coding, each codeword matrix of the STBC constructed using the proposed method has the structure shown in (14) where \( A_0 \) and \( A_1 \) specifically have the structure given in (15) at the top of the page with \( s_{ki}, k = 0, 1 \).

Proposition 1: The rate of the STBC whose codeword matrices have the structure given in (14) is 2 complex symbols per channel use.

Proof: The STBC encodes \( 2nm \) independent complex symbols in \( nm \) channel uses, hence allowing a rate of 2 complex symbols per channel use.

Proposition 2: The STBC-scheme that is based on the STBCs constructed using the proposed method has the NVD property if \( \gamma \in O_F \) and \( \gamma_M \in O_L \).

Proof: With \( L = \mathbb{Q}(i) \) or \( \mathbb{Q}(\omega) \), the ring of integers in \( L \) is either \( \mathbb{Z}[i] \) or \( \mathbb{Z}[\omega] \). When \( \gamma \in O_F \) and \( \gamma_M \in O_L \), application of Corollary 1 establishes that for the infinite STBC whose codewords have the form shown in (14) with \( A_0 \) and \( A_1 \) given by (15) and the symbols taking values from either \( \mathbb{Z}[i] \) or \( \mathbb{Z}[\omega] \) (see Definition 6), the determinant of any nonzero codeword matrix lies in \( \mathbb{Z}[i] \) or \( \mathbb{Z}[\omega] \), the result of the proposition follows.

While our proposed scheme can be applied to a wide range of MIMO configurations, we illustrate its application to 4 MIMO configurations\(^3\) - \( 4 \times 2, 6 \times 2, 8 \times 2 \) and \( 12 \times 2 \) systems. The reason for choosing these 4 configurations is easy to see - the existence of perfect codes [7] for \( 2, 3, 4, 6 \) transmit antennas and the Alamouti code for 2 transmit antennas. The perfect codes of [7] are known for their large coding gain while the Alamouti code has the least ML-decoding complexity among STBCs from CDAs in addition to having the best coding gain among known rate-1 codes for the \( 2 \times 1 \) system. We wish to combine the advantages of both these STBCs and so, we focus on the four mentioned MIMO systems. The STBC design procedure for these four MIMO configurations is briefly outlined as follows, and explicit code constructions are presented in the following subsections. For \( n_1 = 4, 8 \), we

\[^3\]While the constructed STBCs can be used for arbitrary number of receive antennas, they are full-rate only for MIMO systems.
choose $L$ to be $\mathbb{Q}(i)$ while for $n_t = 6, 12$, we choose $L$ to be $\mathbb{Q}(\omega)$. $K$ and $\gamma_M$ are respectively chosen to be the maximal subfield and the non-norm element of the division algebra used to construct the perfect codes for $n_t/2$ transmit antennas. So, $K$ is of the form $L(\theta)$, $\theta \in \mathbb{R}$. Next, $A$ is chosen to be $A = (K/\mathbb{Q}(\theta))$, $\sigma : i \mapsto -i, -1$ which is a subalgebra of Hamilton’s quaternions $A_H = (\mathbb{C}/\mathbb{R}, \sigma : i \mapsto -i, -1)$. The explicit code construction is illustrated in the following subsections.

B. $4 \times 2$ MISO system

We choose $L = \mathbb{Q}(i)$, $K = \mathbb{Q}(i, \sqrt{5})$ and $\gamma_M = i$. The Galois group of $\mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(i)$ is $\{1, \tau : \sqrt{5} \mapsto -\sqrt{5}\}$, and $\mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(i)$, $\tau, i$ is the CDA used to construct the Golden code for 2 transmit antennas. $\gamma_M$ is chosen to be $(\mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(\sqrt{5}), \sigma, -1)$. Note that $\gamma_M = i \notin \mathbb{Q}(\sqrt{5})$. The STBC for the $4 \times 2$ system (unnormalized with respect to SNR) obtained upon application of the construction scheme depicted in the previous section is given as

$$S_{4 \times 2} = \left\{ \begin{array}{c} a_0 - \tau(a_1) \quad i\tau(a_2) \\ a_1 \quad \sigma(a_0) \quad i\tau(a_3) \\ a_2 - \tau(a_3) \quad \tau(a_0) \\ a_3 \quad \sigma(a_2) \quad \tau(a_1) \end{array} \right\}$$

where $a_0 = s_{00}\theta_1 + s_{02}\theta_2, a_1 = s_{01}\theta_1 + s_{03}\theta_2, a_2 = s_{11}\theta_1 + s_{12}\theta_2, a_3 = s_{31}\theta_1 + s_{13}\theta_2$ with $s_{kJ} \in M$-QAM $\subset \mathbb{Z}[i]$, and $\{\theta_1, \theta_2, \theta_3\} \in \mathbb{O}_{K}$ is a suitable $\mathbb{Q}(i)$-basis of $\mathbb{Q}(i, \sqrt{5})$. From [7], we pick $\theta_1 = \alpha, \theta_2 = \alpha\theta$ where $\alpha = 1 + i(1 - \theta)$, $\theta = (1 + \sqrt{5})/2$, and $\{\alpha, \alpha\theta\}$ is now a basis of a principal ideal of $\mathbb{O}_{K}$ generated by $\alpha$. We now wish to prove that the STBC-scheme that is based on $S_{4 \times 2}$ has the NVD property. To do so, it is sufficient from Proposition 2 to prove that $\text{AY}(A) \neq i, \forall A \in \mathbb{A}$.

**Proposition 3:** Let $A = (\mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(\sqrt{5}), \sigma, -1)$. Then, $\text{AY}(A) \neq i, \forall A \in \mathbb{A}$.

The proof of Proposition 3 is given in Appendix D. So, $S_{4 \times 2}$ is a rate-2 STBC with full-diversity and equipped with the property of non-vanishing determinant.

1) Minimum determinant: When $s_{ki}, k = 0, 1, \ldots, 4$, take values from $\mathbb{Z}[i]$, from Corollary 1 the determinant of each of the codewords of $S_{4 \times 2}$ belongs to $\mathbb{Z}[i]$. So, the minimum determinant of the unnormalized is at least 1. However, noting that the entries of the $i$th column of a codeword matrix, $i = 1, \ldots, 4$, are all respectively multiples of $\alpha, \sigma(\alpha), \tau(\alpha)$, and $\sigma(\alpha)$, the minimum determinant is a multiple of $|\alpha\sigma(\alpha)\tau(\alpha)|$ of $|N_{K/\mathbb{C}}(\alpha)|$ is 25 ($\alpha$ is simply complex conjugation). When $s_{ki}$ take values from an $M$-QAM with average energy $E$ units, a normalization factor (see Note 1 in Section II) of $\sqrt{4E|\alpha|^2(1+\sigma^2)}$ has to be taken into account. Further, since the difference between any two signal points in a QAM constellation is a multiple of 2, the normalized minimum determinant of $S_{4 \times 2}$ is $\delta_{\text{min}}(S_{4 \times 2}) = 25 \left( \frac{2}{\sqrt{\text{det}(D)}} \right)^8 = \frac{1}{25e^4}$.  

*Note 4:* The STBC for the $4 \times 2$ MISO system in [20, Section IV-B] makes use of $A = (\mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(i), \sigma : \sqrt{5} \mapsto -\sqrt{5}, i, \tau = \sigma, \gamma_M = 1 - i$. The constructed STBC has NVD, but lower normalized minimum determinant than $S_{4 \times 2}$. Its normalized minimum determinant can be calculated to be $\frac{1}{25e^4}$, which is $(\frac{1}{5})^8 = 0.4096$ times the normalized minimum determinant of $S_{4 \times 2}$, which corresponds to a coding gain that is 0.8 times the coding gain of $S_{4 \times 2}$.

2) Relation with Srinath-Rajan code: A codeword matrix of the SR-code is given by

$$S = \begin{bmatrix} A & e^{i\pi}C \\ e^{-i\pi}B & D \end{bmatrix}$$

where

$$A = \begin{bmatrix} \text{Re}(x_1) + i\text{Im}(x_1) & -\text{Re}(x_2) + i\text{Im}(x_1) \\ \text{Re}(x_2) + i\text{Im}(x_2) & \text{Re}(x_1) - i\text{Im}(x_1) \end{bmatrix},$$

$$B = \begin{bmatrix} \text{Re}(x_3) + i\text{Im}(x_7) & -\text{Re}(x_6) + i\text{Im}(x_8) \\ \text{Re}(x_6) + i\text{Im}(x_6) & \text{Re}(x_3) - i\text{Im}(x_3) \end{bmatrix},$$

$$C = \begin{bmatrix} \text{Re}(x_7) + i\text{Im}(x_8) & \text{Re}(x_5) + i\text{Im}(x_6) \\ \text{Re}(x_6) + i\text{Im}(x_6) & \text{Re}(x_7) - i\text{Im}(x_5) \end{bmatrix},$$

$$D = \begin{bmatrix} \text{Re}(x_3) + i\text{Im}(x_1) & -\text{Re}(x_4) + i\text{Im}(x_2) \\ \text{Re}(x_4) + i\text{Im}(x_2) & \text{Re}(x_3) - i\text{Im}(x_1) \end{bmatrix},$$

with the complex symbols $x_i = e^{i \frac{\pi(i - 1)}{2}}, i \in \mathbb{Z}[i], i = 1, \ldots, 8$ (i.e., from a suitable QAM constellation). Denoting $\tan^{-1}(2)/2$ by $\theta_b$, we have

$$x_i = \cos \theta_b \text{Re}(s_i) - \sin \theta_b \text{Im}(s_i) + i(\sin \theta_b \text{Re}(s_i) + \cos \theta_b \text{Im}(s_i)) \quad \text{and} \quad \theta = (1 + \sqrt{5})/2.$$  

so, it is easy to work out that $S = \text{US}U^H\text{D}$ with $U = \text{diag}[1, 1, e^{i\pi}, e^{2i\pi}]$.

$$S' = \begin{bmatrix} f_0 & -\sigma(f_1) & i\tau(f_2) & -i\sigma(\tau(f_3)) \\ f_1 & \sigma(f_0) & i\tau(f_3) & i\sigma(\tau(f_2)) \\ f_2 & -\sigma(f_3) & \tau(f_0) & -\sigma(\tau(f_1)) \\ f_3 & \sigma(f_2) & \tau(f_1) & \sigma(\tau(f_0)) \end{bmatrix},$$

where $f_0 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_1) + i\text{Im}(s_3)), f_1 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_2) + i\text{Im}(s_4)), f_2 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_2) + i\text{Im}(s_4)), f_3 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_2) + i\text{Im}(s_4)), f_4 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_2) + i\text{Im}(s_4)), f_5 = -\text{Im}(s_1) + i\text{Re}(s_4) + \theta(\text{Re}(s_2) + i\text{Im}(s_4)).$
only conjectured.

C. 6 × 2 MIDO system

For this MIDO configuration, we choose \( L = Q(ω), K = Q(ω, θ) \) and \( γ_M = ω \), where \( ω = 2 \cos \left( \frac{2πj}{8} \right) \) with \( η \) denoting the primitive 7th root of unity. Note that \( (Q(ω, θ)/Q(ω), τ, ω) \) is the CDA used to construct the perfect code for 3 transmit antennas [7] with \( τ \) given by \( τ : η = ω + + η^2, A \) is chosen to be \( (Q(ω, θ)/Q(θ), σ : i → -i) \). Since \( ω = (-1 + \sqrt{3}i)/2, σ(ω) = ω^2 \). It is to be noted that \( γ_M = ω \notin Q(θ) \). The rate-2 STBC (unnormalized with respect to SNR) for 6 transmit antennas is given by

\[
S_{6×2} = \left\{ \begin{array}{ccc}
A_0 & O & ω^2 Υ(A_1) \\
A_1 & Υ(A_0) & O \\
O & Υ(A_1) & T^2(A_0)
\end{array} \right\}
\]

where

\[
A_k = \left[ \begin{array}{ccc}
\sum_{i=1}^{4} s_{ki} θ_i & -σ(\sum_{i=1}^{4} s_{k+3i} θ_i) \\
\sum_{i=1}^{4} s_{ki} θ_i & σ(\sum_{i=1}^{4} s_{k+3i} θ_i)
\end{array} \right]
\]

with \( s_{kj} \in M-HXC \subset Z[i] \), \( k = 0, 1, i = 1, \ldots, 6 \). Here, \( \{θ_1, θ_2, θ_3\} \) is a basis of a principal ideal in \( O_K \) generated by \( θ \) with \( [7] \) \( θ_1 = 1 + ω + \theta, θ_2 = -1 - 2ω + θ^2 \) and \( θ_3 = (1 + 2ω + (1 + ω)θ + (1 + ω)θ^2 \). To prove that the STBC-scheme which is based on \( S_{6×2} \) has the NVD property, it is sufficient to prove that \( AT(A)Υ^2(A) \neq ω, ∀A \in A \).

Proposition 4: \( AT(A)Υ^2(A) \neq ω, ∀A \in (Q(ω, θ)/Q(ω), \sigma, -1) \).

The proof of Proposition 4 is on similar lines to that of Proposition 3 and given in Appendix E.

1) Minimum determinant: When \( sk_1, k = 0, 1, i = 1, \ldots, 6 \), take values from \( Z[i] \), from Corollary 1 the determinant of each of the codewords of \( S_{6×2} \) belongs to \( Z[i] \) and hence the minimum determinant of the unnormalized code is at least 1. However, the perfect code for 3 antennas has its entries from a principal ideal in \( O_K \) generated by \( θ \). So, the minimum determinant of the unnormalized code is at least 1.

D. 8 × 2 MIDO system

\( L \) is chosen to be \( Q(i) \), and \( K = Q(i, θ) \), \( γ_M = ω \), where \( ω = 2 \cos \left( \frac{2πj}{16} \right) \) with \( η \) denoting the primitive 15th root of unity. Note that with \( τ \) given as \( τ : η = ζ_28 + ζ_28^{-1} \rightarrow ζ_28^2 + ζ_28^{-2}, (Q(i, θ)/Q(θ), τ, ω) \) is the CDA used to construct the perfect code for 4 transmit antennas [7]. Next, \( A \) is chosen to be \( (Q(i, θ)/Q(θ), σ, -1) \). It is to be noted that \( γ_M = i \notin Q(θ) \). The rate-2 STBC (unnormalized with respect to SNR) for 8 transmit antennas is given by

\[
S_{8×2} = \left\{ \begin{array}{ccc}
A_0 & O & O \\
A_1 & Υ(A_0) & O \\
O & Υ(A_1) & T^2(A_0) \\
O & O & T^3(A_0)
\end{array} \right\}
\]

where

\[
A_k = \left[ \begin{array}{ccc}
\sum_{i=1}^{4} s_{ki} θ_i & -σ(\sum_{i=1}^{4} s_{k+4} θ_i) \\
\sum_{i=1}^{4} s_{ki} θ_i & σ(\sum_{i=1}^{4} s_{k+4} θ_i)
\end{array} \right]
\]

with \( s_{kj} \in M-QAM \subset Z[i], k = 0, 1, j = 1, \ldots, 8 \). Here, \( \{θ_1, θ_2, θ_3, θ_4\} \) is a basis of \( [7] \) of a principal ideal in \( O_K \) generated by \( θ \), where \( θ_1 = α, θ_2 = αω, θ_3 = αθ(−3 + θ^2) \), \( θ_4 = α(−3 + 2θ^2 + θ^2) \) with \( α = 1 - 3i + i^2 \). To prove that the STBC-scheme which is based on \( S_{8×2} \) has the NVD property, it is sufficient from Proposition 2 to prove that \( AT(A)Υ^2(A)Υ^3(A) \neq ω, ∀A \in A \).

Proposition 5: Let \( A = (Q(i, θ)/Q(θ), σ, -1) \). Then, \( AT(A)Υ^2(A)Υ^3(A) \neq ω, ∀A \in A \).

The proof of Proposition 5 is given in Appendix F.

1) Minimum determinant: When \( sk_{ki}, k = 0, 1, i = 1, \ldots, 8 \), take values from \( Z[i] \), from Corollary 1 the determinant of each of the codewords of \( S_{6×2} \) belongs to \( Z[i] \) and hence the minimum determinant of the unnormalized code is at least 1.

The rate-2 STBC (unnormalized with respect to SNR) for 12 transmit antennas is given by (17) at the top of the next page with

\[
\begin{pmatrix}
z_{ki} \\
τ(z_{ki}) \\
τ^2(z_{ki}) \\
τ^3(z_{ki}) \\
τ^4(z_{ki}) \\
τ^5(z_{ki})
\end{pmatrix} = R
\]

\[
\begin{pmatrix}
s_{ki}(6i+1) \\
s_{ki}(6i+2) \\
s_{ki}(6i+3) \\
s_{ki}(6i+4) \\
s_{ki}(6i+5) \\
s_{ki}(6i+6)
\end{pmatrix}, k = 0, 1, i = 0, 1,
\]

where \( s_{kj} \in M-HXC \subset Z[i], k = 0, 1, j = 1, \ldots, 24 \), and \( R \), defined by (8), is obtained from [7] and shown in (18) at the top of the next page.

As done for the previous STBCs, to prove that the STBC-scheme which is based on \( S_{12×2} \) has the NVD property, it is sufficient to show that \( AT(A)Υ^2(A)Υ^3(A) \neq ω, ∀A \in A \).

Proposition 6: \( AT(A)Υ^2(A)Υ^3(A) \neq ω, ∀A \in (Q(ω, θ)/Q(ω), σ, -1) \).

The proof of Proposition 6 is provided in Appendix G.

1) Minimum determinant: From Corollary 1, the minimum determinant of the unnormalized code is 1. Since the entries of the perfect code for 6 antennas are not in a principal
ideal, a lower bound on the minimum determinant of the unnormalized code is 1. It can be checked that the norm of each row of $\mathbf{R}$ is $\sqrt{14}$. So, taking into account a normalization factor of $1/\sqrt{4(14)}E = \sqrt{56}E$, the normalized minimum determinant of $S_{12x2}$ whose symbols take values from $M$-HEX is at least $\left(\frac{1}{\sqrt{56}}\right)^{24} \approx 12$.

Note 5: Among the four STBCs constructed, $S_{12x2}$ and $S_{8x2}$ have orthogonal generator matrices (see Definition 1 and Definition 3) and hence have cubic shaping while the other two codes do not.

V. ML-DECODING COMPLEXITY

In this section, we analyze the ML-decoding complexity of the constructed STBCs as a function of the constellation size $M$ which is assumed to be a square integer. Consider the ML-decoding metric given by $||Y - \sqrt{7HS}||^2$ which is to be minimized over all possible codewords $S \in S$. We have

$$||Y - \sqrt{7HS}||^2 = \text{tr} \left( (Y - \sqrt{7HS})(Y - \sqrt{7HS})^H \right)$$

$$= \text{tr} \left( YY^H - \sqrt{7}YSH^H \right) - \sqrt{7}SY^HS^H + \rho \text{HS}^{-1}H^H$$

$$= \text{tr} \left( YY^H \right) - 2\sqrt{\rho} \text{Re} \left( \text{tr} \left( \text{HS}^H \right) \right) + \rho \text{tr} \left( \text{HS}^{-1}H^H \right).$$

Now, expressing a codeword $S$ as $\sum_{i=1}^k (s_i\hat{A}_i + s_i\hat{\Phi}_i)$ (see (3)), where $s_i, \tilde{s}_i \in \sqrt{M}$-PAM, we get

$$\text{tr} \left( \text{HS}^H \right) = \sum_{i=1}^k (\tilde{s}_i \text{tr} \left( \text{H}\hat{A}_i \right) + \tilde{s}_i \text{tr} \left( \text{H}\hat{\Phi}_i \right)), \text{ and}$$

$$\text{tr} \left( \text{HS}^{-1}H^H \right) = \sum_{i=1}^k n_{ii} \tilde{s}_i^2 + \sum_{i=1}^k m_{ii} \tilde{s}_i^2$$

$$+ \sum_{i=1}^{k-1} \sum_{j=i+1}^k p_{ij} \tilde{s}_i \tilde{s}_j + \sum_{i=1}^{k-1} \sum_{j=i+1}^k q_{ij} \tilde{s}_i \tilde{s}_j$$

$$+ \sum_{i=1}^k \sum_{j=1}^k r_{ij} \tilde{s}_i \tilde{s}_j$$

where

$$n_{ii} = \text{tr} \left( \text{T}\hat{A}_i \hat{\Phi}_i \hat{H}^H \right), \text{ and} \quad m_{ii} = \text{tr} \left( \text{T}\hat{A}_i \hat{A}_i^H \hat{H}^H \right),$$

$$p_{ij} = \text{tr} \left( \text{T}\hat{A}_i \hat{A}_j + \hat{A}_j \hat{A}_i^H \hat{H}^H \right),$$

$$q_{ij} = \text{tr} \left( \text{T}\hat{A}_i \hat{A}_j + \hat{A}_j \hat{A}_i^H \hat{H}^H \right),$$

$$r_{ij} = \text{tr} \left( \text{T}\hat{A}_i \hat{A}_j + \hat{A}_j \hat{A}_i^H \hat{H}^H \right).$$

Therefore, the only term in the ML-decoding metric that has an entanglement of the information symbols is $\rho \text{tr} \left( \text{HS}^{-1}H^H \right)$.

Hence, $\text{SS}^H$ defines the ML-decoding complexity of the STBC. Now, let $z_1 = \sum_{i=1}^n s_i \theta_i$, $z_2 = \sum_{i=1}^n s_i \theta_i$, where $s_i$ take values from either QAM or HEX constellations, $\theta_i \in \mathbb{C}$. If the transmitted codeword is

$$S = \begin{bmatrix} z_1 & -\sigma(z_2) \\ z_2 & \sigma(z_1) \end{bmatrix}$$

where $\sigma$ performs complex conjugation, $\text{SS}^H = (|z_1|^2 + |z_2|^2)I$. Hence, the group of symbols $\{s_i, i = 1, \ldots, n\}$ that $z_1$ consists of are disentangled in the decoding metric from $\{s_2, i = 1, \ldots, n\}$ that $z_2$ consists of. So, $\{s_i, i = 1, \ldots, n\}$ can be decoded independently of $\{s_2, i = 1, \ldots, n\}$. In addition, if $s_i$ take values from a square QAM constellation and $\theta_i$, $i = 1, \ldots, n$, are of the form $\theta_i = \alpha \theta_i^\prime$ where $\alpha \in \mathbb{C}$ and $\theta_i^\prime \in \mathbb{R}$, then within each group $\{s_k, i = 1, \ldots, n\}$, $k = 1, 2$, the group comprising the real parts of each symbol is separable from the group comprising the imaginary parts.

Hence,

1) when $s_k$ takes values from a square QAM, the four groups $\{\text{Re}(s_{1i}), i = 1, \ldots, n\}$, $\{\text{Im}(s_{1i}), i = 1, \ldots, n\}$, $\{\text{Re}(s_{2i}), i = 1, \ldots, n\}$ and $\{\text{Im}(s_{2i}), i = 1, \ldots, n\}$, are independently decodable of one another.

2) when $s_k$ takes values from a HEX constellation, the two groups $\{s_{1i}, i = 1, \ldots, n\}$ and $\{s_{2i}, i = 1, \ldots, n\}$ are independently decodable of one another.

So, we have the following proposition.

**Proposition 7:** Let the codeword matrices of an STBC $S$ be block diagonal of the form $S = \text{diag} \left[ \mathbf{A}, \mathbf{Y}(\mathbf{A}), \ldots, \mathbf{Y}^{n-1}(\mathbf{A}) \right]$ where

$$\mathbf{A} = \begin{bmatrix} \sum_{i=1}^n s_1 \theta_i & -\sigma(\sum_{i=1}^n s_2 \theta_i) \\ \sum_{i=1}^n s_2 \theta_i & \sigma(\sum_{i=1}^n s_1 \theta_i) \end{bmatrix}.$$
\[ \mathcal{T}(A) = \begin{bmatrix} \tau^l (\sum_{i=1}^n s_{1i} \theta_i) & -\sigma \tau^l (\sum_{i=1}^n s_{2i} \theta_i) & \sigma \tau^l (\sum_{i=1}^n s_{1i} \theta_i) \\ \end{bmatrix} \]

and \( \{ \theta_i, i = 1, \ldots, n| \theta_i \in \mathbb{Q}(K) \} \) is a \( \mathbb{Q}(i) \)-basis (or \( \mathbb{Q}(\omega) \)-basis) of a number field \( K \) which is a Galois extension of degree \( n \) over \( \mathbb{Q}(i) \) (respectively \( \mathbb{Q}(\omega) \)) with Galois group \( \langle \tau \rangle \). If \( \theta_i, i = 1, \ldots, n \), are of the form \( \theta_i = \alpha \theta_i' \) where \( \alpha \in \mathbb{C} \) and \( \theta_i' \in \mathbb{R} \), then \( S \) is

1. four-group decodable if \( s_{ki} \) take values from QAM.
2. two-group decodable if \( s_{ki} \) take values from HEX.

\[ \begin{align*}
\text{Proof:} & \quad \text{The proof is trivial and follows from the argument preceding the proposition.} \\
& \end{align*} \]

Following Proposition 7, the ML-decoding complexity of the codes constructed in this paper is easy to analyze. We express a codeword matrix of the STBC as \( S = S(A_0) + S(A_1) \), where

\[ S(A_0) = \text{diag} \left[ A_0, \mathcal{T}(A_0), \cdots, \mathcal{T}^{n-1}(A_0) \right], \quad n = n_t/2, \]

and

\[ S(A_1) = \begin{bmatrix} O & O & \cdots & \gamma_{A_1} \mathcal{T}^{n-1}(A_1) \\ A_1 & O & \cdots & O \\ O & \mathcal{T}(A_1) & \cdots & O \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & O \end{bmatrix}. \]

Both \( S(A_0) \) and \( S(A_0) \) contain \( n_t \) complex information symbols each. So,

\[ \min_{S \in S} \left\{ || Y - \sqrt{\rho} HS ||^2 \right\} = \min_{S(A_1)} \left\{ \min_{S(A_0)} \left\{ || Y' - \sqrt{\rho} HS(A_0) ||^2 \right\} \right\} \]

where \( Y' = Y - \sqrt{\rho} HS(A_1) \). Assuming that the complex constellations used are \( M \)-QAM or \( M \)-HEX, from Proposition 7, it can be noted that calculating \( \min_{S(A_0)} \left\{ || Y' - \sqrt{\rho} HS(A_0) ||^2 \right\} \) requires only \( \mathcal{O} \left( M^{\frac{n_t}{2}} \right) \) calculations (for \( n_t = 4, 8 \)) and \( \mathcal{O} \left( M^\frac{n_t}{2} \right) \) calculations (for \( n_t = 6, 12 \)). Therefore, the overall ML-decoding complexity of the STBCs is \( \mathcal{O} \left( M^{n_t} M^{\frac{n_t}{2}} \right) = \mathcal{O} \left( M^{\frac{3n_t}{2}} \right) \) for \( n_t = 4, 8 \), while for \( n_t = 6, 12 \), it is \( \mathcal{O} \left( M^{n_t} M^{\frac{n_t}{2}} \right) = \mathcal{O} \left( M^{\frac{3n_t}{2}} \right) \). In addition, hard-limiting (see [2] for details) further reduces the overall ML-decoding complexity by a factor of \( \sqrt{M} \). Table I captures the salient features of the constructed codes along with their comparison with some of the best known STBCs.

**VI. COMPARISON WITH EXISTING STBCS**

We compare the performance of the STBCs constructed in this paper with some of the best known STBCs.

**A. 4 \times 2 MIDO system**

As rival codes for \( S_{4 \times 2} \), we consider the following four STBCs - the punctured perfect code for 4 transmit antennas (two of its layers have zero entries), the BHV code [15], the rate-2 STBC called \( A_4 \) code which is obtained in [1, Section VIII-A], and a new STBC obtained by puncturing \( C_4 \) [35]. \( A_4 \) has been shown [1] to be the best performing code among all the linear STBCs proposed in [1] for the \( 4 \times 2 \) MIDO system. The fourth rival code is obtained from \( C_4 \) by simply puncturing the symbols corresponding to the basis elements \( \zeta_5^2 \) and \( \zeta_5^3 \), i.e., the entries of the first column of the codeword matrices are of the form \( s_{i1} + s_{i2} \zeta_5 \). This STBC has the best coding gain which can be explicitly calculated and is shown in Table I. Even though the BHV code is not a full-diversity STBC, it is considered here since it is the first fast-decodable STBC proposed for the \( 4 \times 2 \) system, having an ML-decoding complexity of \( \mathcal{O}(M^{4.5}) \) for square \( M \)-QAM. We have not considered the other full-diversity STBCs proposed in [16] - [20] since these codes have not been constructed with a focus on coding gain but only with an intention of having fast-decodability with a proven NVD. The constellations used in our simulations are 4-QAM and 16-QAM.

Fig. 1 reveals that \( S_{4 \times 2} \) has the best error performance among all codes under comparison, although punctured \( C_4 \) has the best coding gain. This can possibly be attributed to
the multiplicity of the minimum determinant - the number of codeword-difference matrices whose squared absolute value of determinant is the actual minimum determinant. We believe that punctured $C_4$ has more such pairs since it is obtained by puncturing $C_4$ and our method of puncturing might not be efficient. Punctured $C_4$ loses only slightly to $S_{4×2}$ and these two codes beat the other three STBCs for both 4- and 16-QAM.

B. 6 × 2 MIDO system

For this system, the rival codes for $S_{6×2}$ are the punctured perfect code for 6 antennas [7] (4 layers punctured), punctured $C_6$ [35], and two versions of the VHO-code for 6 transmit antennas [1, Section X-C]. $C_6$ is obtained from the CDA $(\mathbb{Q}(\omega, \zeta_7)/\mathbb{Q}(\omega), \tau : \zeta_7 \mapsto \zeta_7^2, -\omega)$, where $\zeta_7$ is the primitive $7^{th}$ root of unity. The entries of the first column of the codeword matrices of the punctured $C_6$ are of the form $s_{11} + s_{12} \zeta_7, s_{12} \in M$-HEX. The VHO-code for 6 transmit antennas is a rate-3 STBC obtained from the CDA $(\mathbb{Q}(\zeta_7)/\mathbb{Q}(\omega), \sigma : \zeta_7 \mapsto \zeta_7^2, -3/4)$. The first version of the VHO-code for the 6 × 2 system is obtained by puncturing the rate-3 VHO-code to obtain a rate-2 STBC, with the method of puncturing as depicted in [1, Section X-C]. This STBC has an ML-decoding complexity of $O(M^{8.5})$. The second version of the rate-2 VHO-code is obtained by using the $\mathbb{Q}$-basis of $\mathbb{Q}(\zeta_7)$ to be $\{\zeta_7 + \zeta_7^2, \zeta_7 - \zeta_7^2, \zeta_7^2 - \zeta_7, \zeta_7^2 + \zeta_7^2, \zeta_7^2 - \zeta_7^2\}$ instead of the integral basis $\{1, \zeta_7, \zeta_7^2, \zeta_7^3, \zeta_7^4\}$. This change of basis results in the overall ML-decoding complexity being only $O(M^7)$ (Note that all the ML-decoding complexities are calculated after employing hard-limiting). Both versions of the VHO-code use 4-QAM while the other STBCs use 4-HEX constellation.

Fig 2 shows that $S_{6×2}$, the punctured perfect code, and the first version of the VHO-code (marked as “VHO-Code -Puncturing 1” in the figure) have a very similar error performance. The second version of the VHO-code has poorer error performance but lower ML-decoding complexity. The best performance is that of punctured $C_6$ which has the largest normalized minimum determinant.

VII. DISCUSSION

In this paper, we proposed a new method to obtain full-diversity, rate-2 STBCs from nonassociative algebras. We then constructed rate-2, fast-decodable STBCs for $4 \times 2, 6 \times 2, 8 \times 2$ and $12 \times 2$ systems which have large normalized minimum determinants, and STBC-schemes consisting of these STBCs have a non-vanishing determinant (NVD) so that they are DMT-optimal for their respective MIDO systems. We also showed that the Srinath-Rajan code has the same algebraic structure as the STBC constructed in this paper for the $4 \times 2$ system, thereby proving a previous conjecture that the STBC-scheme based on the Srinath-Rajan code has the NVD property and hence is DMT-optimal for the $4 \times 2$ system. However, there is still scope for improvement. Firstly, with the exception of the STBC for $4 \times 2$ MIDO system, the remaining STBCs in this paper have a lot of zero entries and naturally, there is the issue of high peak to average power ratio (PAPR) which needs to be lowered. Secondly, it is natural to seek conditions that enable the construction of higher rate codes (rate > 2) with high coding gain and fast-decodability on the lines of the STBCs constructed in this paper. These are the possible directions for future research.

APPENDIX A

PROOF OF THEOREM 1

From Lemma 1, we know that $A_0 + iA_1$, when it has a right inverse, has a unique right inverse if and only if it is not a left zero divisor. To prove the theorem, we first show that any element $A_0 + iA_1 \in M_A$ is a left zero divisor if and only if equality holds in (13). Following this, we show the existence of the right inverse to complete the proof of the theorem.

Suppose that $A_0 + iA_1$ is a left zero divisor of an element $B_0 + iB_1 + \cdots + i^{n-1}B_{n-1}$, $B_i \in A$. Since $A_0$ and $A_1$ are from $A$ which is a CDA, we can assume that neither of $A_0$ and $A_1$ is zero since otherwise the unique right inverse always exists. Now, from our assumption,

\[(A_0 + iA_1)(B_0 + iB_1 + \cdots + i^{n-1}B_{n-1}) = 0.\]

So, noting that $A_1$ is invertible with its right inverse denoted by $A_1^{-1}$ (also its left inverse as elements of a CDA have the same left and right inverses), we have

\[(A_0' + i)(B_0' + iB_1' + \cdots + i^{n-1}B_{n-1}') = 0\]

where $A_0' = A_0 A_1^{-1}$, $B_i' = \Upsilon^i(A_1)B_i$, $i = 0, 1, \cdots, n - 1$.

Due to the linear independence of $1, i, \cdots, i^{n-1}$ over $A$, we have

\[A_0'B_0' + \gamma_M B_{n-1}' = 0,\]

\[B_k' - \Upsilon_k(A_0')B_k' = 0, \quad k = 1, \cdots, n - 1.\]  

(19)  

(20)

From (19), (20) and the fact that $A_0' \neq 0$, it is clear that $B_i' \neq 0$, $i = 0, 1, \cdots, n - 1$. Solving (20), we arrive at $B_0' = (-1)^{n-1}\Upsilon(A_0')\Upsilon^2(A_0') \cdots \Upsilon^{n-1}(A_0')B_{n-1}'$ using which in (19), we obtain

\[\left[(-1)^{n-1} A_0' \Upsilon(A_0') \Upsilon^2(A_0') \cdots \Upsilon^{n-1}(A_0') + \gamma_M\right]B_{n-1}' = 0.\]

Since $B_{n-1}' \neq 0$, we have $A_0' \Upsilon(A_0') \Upsilon^2(A_0') \cdots \Upsilon^{n-1}(A_0') = (-1)^{n\gamma_M}.\quad$ Taking $-A_0' = C$, we have

\[C\Upsilon(C) \Upsilon^2(C) \cdots \Upsilon^{n-1}(C) = \gamma_M.\]

(21)

So, elements of the form $A_0 + iA_1$ are left zero divisors if and only if (21) is satisfied. Therefore, if no $C \in A$ satisfies (21), any element of the form $A_0 + iA_1$ has a unique right inverse which can be computed by equating the left hand side of (19) with 1. The resulting right inverse is obtained to be

\[B = B_0 + iB_1 + \cdots + i^{n-1}B_{n-1}\]

\[B_i = \left[\Upsilon^i(A_1)\right]^{-1}B_i', \quad i = 0, 1, \cdots, n - 1, \quad (22)\]

\[B_{n-1}' = \left[(-1)^{n-1} \prod_{i=0}^{n-1} \Upsilon^i(A_0') + \gamma_M\right]^{-1}, \quad (23)\]

\[B_{n-k}' = (-1)^{k-1}\left(\prod_{i=n-k+1}^{n-1} \Upsilon^i(A_0')\right)B_{n-1}' \quad (24)\]

and $A_0' = A_0 A_1^{-1}$. This completes the proof of Theorem 1.
Appendix B
Proof of Lemma 2

For convenience, we denote $\text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C)$ by $N_C \in \mathbb{R}^{m \times m}$. We first note that $N_C - \gamma_M I$ is not invertible if and only if $\gamma_M$ is an eigenvalue of $N_C$. This is because if $\gamma_M$ is indeed an eigenvalue of $N_C$, then $N_C x = \gamma_M x$ so that $N_C - \gamma_M I$ is not full-rank. Conversely, if $N_C - \gamma_M I$ is not full-rank, we have $\gamma_M$ to be one of its eigenvalues. We now proceed to prove that $\gamma_M$ is not an eigenvalue of $N_C$, when $\text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C) \neq N_C \neq \gamma_M$ for any $C \in \mathcal{A}$.

Suppose that $\gamma_M$ is an eigenvalue of $N_C$. We first establish that the eigenvector of $N_C$ associated with $\gamma_M$ has entries in $K$. Since $\gamma_M$ is an element of the maximal subfield $K$, the entries of the rank-deficient matrix $N_C - \gamma_M I$ are all elements of $K$. Hence, $N_C - \gamma_M I$ can be viewed as the matrix of a linear transformation from the $m$-dimensional vector space $K^{m \times 1}$ (over $K$) to itself with the kernel of the transformation being nontrivial and consisting of the eigenvectors of $N_C$ associated with $\gamma_M$. We choose one such eigenvector and denote it by $e$. So, we have

$$N_C e = \gamma_M e.$$  \hfill (25)

Now, we note that $N_C$ is also obtained by left regular representation (27) as the matrix of the linear transformation $N_{NC} : A \rightarrow A$, with $\lambda_{NC}(B) = N_C B, \forall B \in A$. Observing that any element of $A$ can be expressed as $[1, j, \ldots, j^{m-1}]k$, $k \in K^{m \times 1}$, let $E = [1, j, \ldots, j^{m-1}]$, with $e$ defined in (25). So,

$$\lambda_{NC}(E) = N_C E = \begin{bmatrix} 1, j, \ldots, j^{m-1} \end{bmatrix} N_C e = \begin{bmatrix} 1, j, \ldots, j^{m-1} \end{bmatrix} \gamma_M e = E \gamma_M,$$  \hfill (26)

where (26) is by definition of left regular representation, (27) is due to (25), and (28) follows by noting that $\gamma_M$ is an element of $K$. Hence, $E^{-1} N_C E = \gamma_M$. Since we have denoted $\text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C)$ by $N_C e = \gamma_M e$, we have

$$\gamma_M = E^{-1} \text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C) E = E^{-1} \text{CT}(C) \Upsilon(E) \Upsilon^2(E) \cdots \Upsilon^{n-1}(E) \Upsilon(C)$$

$$= C'\Upsilon(C')\Upsilon^2(C')\cdots \Upsilon^{n-1}(C')$$  \hfill (29)

where $C' \triangleq E^{-1} \text{CT}(C)$ and (29) is obtained using (11) and (12) and also noting that $(\Upsilon(E))^{-1} = E^{-1} \Upsilon(E^{-1})$ (since $(\Upsilon(E)) \Upsilon(E^{-1}) = \Upsilon(EE^{-1}) = 1$). But (29) leads to a contradiction since there exists no $C \in \mathcal{A}$ such that $\text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C) = \gamma_M$. Therefore, $\gamma_M$ is never an eigenvalue of $\text{CT}(C)\Upsilon^2(C)\cdots \Upsilon^{n-1}(C)$ which proves Lemma 2.

3In general, for any square matrix with entries from a field $K$, its eigenvalues and the entries of the associated eigenvectors need not be in $K$ but will be in the algebraic closure of $K$.

Appendix C
Proof of Theorem 2

Let $A_{\text{mat}}$ be the ring of $m \times m$ sized invertible matrices that are representations of elements of $A$, i.e.,

$$A_{\text{mat}} = \{ A | A \text{ is the matrix representation of } A \in A \}.$$

We have already assumed that $\gamma_M$ does not belong to the centre of $A$ and so does not commute with every element of $A$ because of which $M_{\text{mat}}$ does not have a matrix representation in $M_{mn}(K)$. But every element of $A_{\text{mat}}$ commutes with $\gamma_M I$ (which is not the matrix representation of $\gamma_M$ in $M_{mn}(K)$ and does not belong to $A_{\text{mat}}$). For any finite or infinite set $P$ of $m \times m$ sized matrices, we use the notation $A_{\text{mat}}(P)$ to denote the ring of $m \times m$ matrices generated by $P$ over $A_{\text{mat}}$.

We now consider the ring $A_{\text{mat}}[\gamma_M I]$ which is not a division ring (for example, if $\Gamma_M$ denotes the matrix representation of $\gamma_M$ in $M_{mn}(K)$, then $\Gamma_M - \gamma_M I$ is invertible). Let

$$A_{\text{inv-mat}} = \{ BB^{-1} | BB^{-1} \in A_{\text{mat}}[\gamma_M I] \},$$

i.e., the set of inverses of all invertible matrices in $A_{\text{mat}}[\gamma_M I]$. Next, consider the finite ring $M$ whose elements are matrices of the form

$$B = \begin{bmatrix} B_0 & \cdots & \gamma_M & \cdots & \gamma_M \Upsilon^{n-1}(B_1) \\ \gamma_M & \cdots & \gamma_M & \cdots & \gamma_M \Upsilon^{n-1}(B_2) \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \gamma_M & \cdots & \gamma_M & \cdots & \gamma_M \Upsilon^{n-1}(B_3) \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ B_{n-1} & \cdots & \gamma_M \Upsilon^{n-1}(B_n) & \cdots & \gamma_M I \end{bmatrix}$$  \hfill (30)

where $B_i \in A_{\text{mat}}[\gamma_M I] \cup A_{\text{inv-mat}}[\gamma_M I]$, $i = 0, \ldots, n - 1$. With these facts developed, we proceed with the proof of the theorem as follows.

1) Proof that $M$ is invertible: Let $B = B_0 + iB_1 + \cdots + i^{n-1}B_{n-1}$ be the unique right inverse of $A_0 + iA_1$ given by (22) - (24) with $A_0, A_1, B_0, \ldots, B_{n-1} \in A$. Let

$$A_0' \triangleq A_0 A_1^{-1},$$ \hfill (31)

$$B_{n-1}' \triangleq \begin{bmatrix} (-1)^{n-1} \prod_{i=0}^{n-1} \Upsilon^i(A_0') + \gamma_M I \end{bmatrix}^{-1},$$ \hfill (32)

$$B_{n-k}' \triangleq \begin{bmatrix} (-1)^{n-k-1} \prod_{i=n-k+1}^{n-1} \Upsilon^i(A_0') \end{bmatrix}^{-1},$$ \hfill (33)

$$B_i' \triangleq \Upsilon^i(A_1) (B_{n-i}'), \quad i = 0, 1, \ldots, n - 1.$$ \hfill (34)

The existence of $B_{n-1}'$ can be verified by applying Theorem 1 and Lemma 2 in that order. The inverse of $M$ has the form shown in (30) with $B_i'$ obtained using (31)-(34). To check that this matrix, denoted by $M_{\text{inv}}$, is indeed the inverse of $M$, note that both $M$ and $M_{\text{inv}}$ belong to $M$ and hence their product also is in $M$. So, it only suffices to check that the first $m$ columns of the product of $M$ and $M_{\text{inv}}$ are $[I, 0, 0, \ldots, 0]^T$, which follows upon using (31)-(34).

2) Proof that $\text{det}(M) \in L$: It can be noted that $M \in K^{nm \times nm}$ so that $\text{det}(M) \in K$. Also, $\tau^i(\text{det}(M)) = \text{det}(\Upsilon^i(M))$ where, as mentioned before, $\Upsilon^i(M)$ refers to the matrix obtained by applying $\tau^i$ to each entry of $M$, $i = 0, 1, \ldots, n - 1$. To prove that $\text{det}(M) \in L$, it suffices to show that $\text{det}(\Upsilon(M)) = \text{det}(M)$ since the only elements
fixed by \( \text{Gal}(K/L) = \langle \tau \rangle \) are the elements of \( L \). Let \( P(i,j) \) denote the \((i,j)\)th entry of a matrix \( P \). Consider permutation matrices \( P_1 \) and \( P_2 \) whose nonzero elements are

\[
\begin{align*}
P_1(k, (n-1)m + k) &= 1, \ k = 1, 2, \ldots, m, \\
P_1(k, k - m) &= 1, \ k = m + 1, m + 2, \ldots, nm, \\
P_2(k, k + m) &= 1, \ k = 1, 2, \ldots, (n-1)m, \\
P_2(k, k - (n-1)m) &= 1, \ k = (n-1)m + 1, \ldots, nm.
\end{align*}
\]

Now, \( P_1 \) \( \Upsilon(M)P_2 \) has the following structure.

\[
\begin{bmatrix}
A_0 & O & \cdots & O & \cdots & \Upsilon^{n-1}(A_1) \\
\gamma_M A_1 & \Upsilon(A_0) & \cdots & O & \cdots & O \\
O & \Upsilon(A_1) & \cdots & \cdots & \cdots & O \\
O & O & \cdots & \Upsilon^{-1}(A_0) & \cdots & O \\
\vdots & \vdots & \cdots & \cdots & \cdots & \vdots \\
O & O & \cdots & O & \cdots & \Upsilon^{-1}(A_0)
\end{bmatrix}
\]

(35)

Therefore, with diagonal matrices \( G_1 \) and \( G_2 \) whose nonzero diagonal elements are defined as

\[
\begin{align*}
G_1(k, k) &= \gamma_M, \ k = 1, 2, \ldots, m, \\
G_1(k, k) &= 1, \ k = m + 1, \ldots, nm, \\
G_2(k, k) &= \gamma_M^{-1}, \ k = 1, 2, \ldots, m, \\
G_2(k, k) &= 1, \ k = m + 1, \ldots, nm,
\end{align*}
\]

we observe that

\[
M = G_1P_1\Upsilon(M)P_2G_2.
\]

Therefore,

\[
det(M) = det(\Upsilon(M))
\]

since \( det(G_1)det(G_2) = 1 \) and \( P_1 \) and \( P_2 \) are permutation matrices. As a result, \( det(M) \in L \).

**APPENDIX D**

**PROOF OF PROPOSITION 3**

Let \( A = a + jb \), \( a, b \in \mathbb{Q}(i, \sqrt{5}) \). Suppose that

\[
\Upsilon(A) = i.
\]

(36)

Now, if \( b = 0 \), then \( a\tau(a) = i \) which is not a possibility in \( \mathbb{Q}(i, \sqrt{5})/\mathbb{Q}(i) \) (which has \( i \) as its non-norm element). If \( a = 0 \), we have \( jb\tau(b) = i \) so that

\[
\sigma(b)\tau(b) = -i.
\]

(37)

Applying \( \sigma \) throughout in (37), we get \( b\sigma(b) = i \). Next, applying \( \tau \) throughout in (37), we get \( b\tau(b) = -i \) which leads to a contradiction. So, (37) is not true (Note that \( \tau^2 \) is identity and \( \tau\sigma = \sigma\tau \)) and we can assume that \( a, b \neq 0 \). Now, applying \( \Upsilon \) throughout in (36), we obtain \( \Upsilon(A) = i \). Hence,

\[
(a + jb)(\tau(a) + j\tau(b)) = (\tau(a) + j\tau(b))(a + jb)
\]

which leads to

\[
\frac{\sigma(b)}{\sigma\tau(b)} = \frac{b}{\tau(b)} \frac{\tau(b)}{\tau(b)} = \frac{b}{\tau(b)}
\]

(38)

Hence, \( b/\tau(b) \) is invariant under \( \sigma \) and hence belongs to \( \mathbb{Q}(\sqrt{5}) \). Also, from (36), we have

\[
\begin{align*}
\sigma(a) - \sigma(b)\tau(b) &= i \quad (39)
\end{align*}
\]

so that

\[
\frac{b}{\tau(b)} = -\frac{\sigma(a)}{\tau(a)}.
\]

(40)

Using (40) in (39), we obtain

\[
\frac{\tau(a)}{\sigma(a)} (a\sigma(a) + b\sigma(b)) = i.
\]

Now, \( a\sigma(a) + b\sigma(b) \) is invariant under \( \sigma \) and hence is in \( \mathbb{Q}(\sqrt{5}) \). So, \( \tau(a)/\sigma(a) \) is imaginary and belongs to \( \mathbb{Q}(i, \sqrt{5}) \) using which in (40), we note that \( b/\tau(b) \) is also imaginary. This contradicts the earlier result obtained below (38). Therefore, our assumption that \( \Upsilon(A) = i \) is false which proves the lemma.

**APPENDIX E**

**PROOF OF PROPOSITION 4**

Let \( A = a + jb \), \( a, b \in \mathbb{Q}(\omega, \theta) \) such that

\[
\Upsilon(A)\Upsilon^2(A) = \omega.
\]

(41)

Firstly, \( a \neq 0 \) since otherwise \( (jb)(j\tau(b))(j\tau^2(b)) = \omega \) which is not possible. Secondly, \( b \neq 0 \) since \( a\tau(a)\tau^2(a) = \omega \) for any \( a \in \mathbb{Q}(\omega, \theta) \) (for \( \omega \) is a non-norm element in \( \mathbb{Q}(\omega, \theta)/\mathbb{Q}(\omega, \tau) \)). Hence, we assume that \( a, b \neq 0 \). Applying \( \Upsilon^2 \) throughout in (41), we obtain \( \Upsilon^2(A)\Upsilon^2(A) = \omega \) so that \( \Upsilon^2(A)\Upsilon^2(A) = \Upsilon^2(A)\Upsilon^2(A) \). Now, \( \Upsilon^2(A) = x + j\sigma(y) \) where \( x = \sigma(x) - \sigma(b)\tau(b), \sigma(y) = b\sigma(a) + \sigma(a)\tau(b) \). So,

\[
(x + j\sigma(y)) (\tau^2(a) + j\tau^2(b)) = (\tau^2(a) + j\tau^2(b)) (x + j\sigma(y))
\]

from which we have

\[
\sigma(y)\tau^2(a) + \sigma(x)\tau^2(b) = \sigma^2(a)\sigma(y) + x\tau^2(b).
\]

(42)

From (41), we obtain

\[
\begin{align*}
\sigma(x)\tau^2(a) - \sigma(y)\tau^2(b) &= \omega \quad (43) \\
\sigma(x)\tau^2(b) + \sigma(y)\tau^2(a) &= 0.
\end{align*}
\]

(44)

If \( x = 0 \), then \( y = 0 \) (since \( a \neq 0 \)) and (43) is not true. So, we can assume \( x \neq 0 \). Using (42) and (44), we get

\[
\frac{\sigma(y)}{\tau^2(a)} = -\frac{x}{\sigma\tau^2(a)} = -\frac{\sigma(x)}{\tau^2(a)}
\]

so that

\[
\frac{\sigma(x)}{\tau^2(a)} = \sigma\left(\frac{x\tau^2(a)}{\sigma(x)}\right).
\]

Therefore, \( x/\sigma\tau^2(a) \) is real-valued and belongs to \( \mathbb{Q}(\theta) \). Now, using (44) in (43), we get

\[
\frac{\sigma^2(a)}{\sigma(x)} [x\sigma(x) + y\sigma(y)] = \omega
\]

Since \( x\sigma(x) + y\sigma(y) \) is invariant under \( \sigma \) and hence real-valued, \( \frac{\sigma^2(a)}{\sigma(x)} \) must be complex-valued which contradicts the previous result. Hence, (41) is false and there exists no \( A \in A \) such that \( \Upsilon(A)\Upsilon^2(A) = \omega \).
APPENDIX F

PROOF OF PROPOSITION 5

Let $A = a + j b$, $a, b \in \mathbb{Q}(i, \theta)$ such that

$$A^2 = A^3 = i.$$  \hspace{1cm}  (45)

Applying $T^2$ throughout (45), we obtain

$$A^2(A)^2 = A^3(A) = i$$ so that $A^2(A)^2 = A^3(A) = 1$. Let $A^2(A) = x + j y$ where $x = a \tau(a) - \sigma(b) \tau(b)$, $y = b \tau(a) + \sigma(a) \tau(b)$. So, we have

$$(x + j y)(\tau^2(x) + j \tau^2(y)) = (\tau^2(x) + j \tau^2(y))(x + j y)$$

from which we obtain

$$y \tau^2(x) + \sigma(x) \tau^2(y) = \sigma \tau^2(x) y + x \tau^2(y).$$  \hspace{1cm}  (46)

From (45), we obtain

$$x \tau^2(x) - \sigma(y) \tau^2(y) = i$$ \hspace{1cm}  (47)

$$\sigma(x) \tau^2(y) + y \tau^2(x) = 0.$$  \hspace{1cm}  (48)

Now, if $x = 0,$

$$\sigma(y) \tau^2(y) = -i.$$ \hspace{1cm}  (49)

By applying $\sigma$ and $\tau^2$ separately throughout (49), we obtain

$y \sigma \tau^2(y) = i$ and $\sigma \tau^2(y) = -i$ which contradict each other. Hence, $x \neq 0$. On the other hand, if $y = 0$, then $x \tau^2(x) = i$ and applying $\tau$ we get $\tau(x) \tau^2(x) = i$ so that $x \tau^2(x) \tau^2(x) = (i)(i) = -1$. Since $x \in \mathbb{Q}(i, \theta)$, this implies that there exists some $x \in \mathbb{Q}(i, \theta)$ such that

$$N_{Q(i, \theta)/Q(i)}(x) = -1.$$  \hspace{1cm}  (50)

This is not true since $i^2$ is not a norm of any field element of $\mathbb{Q}(i, \theta)$ for $t = 1, 2, 3$. Hence, we can assume that $x, y \neq 0$. Using (46) and (48), we get

$$\frac{\sigma \tau^2(x)}{\sigma(x)} = \sigma \frac{\tau^2(x)}{\sigma(x)}$$

so that $\sigma \frac{\tau^2(x)}{\sigma(x)} = \sigma \frac{\tau^2(x)}{\sigma(x)}$. Therefore, $\sigma \frac{\tau^2(x)}{\sigma(x)}$ is real-valued and belongs to $\mathbb{Q}(\theta)$. Now, using (48) in (47), we get

$$\tau^2(x) \left[ x \sigma(x) + y \sigma(y) \right] = i.$$  \hspace{1cm}  (51)

Since $x \sigma(x) + y \sigma(y)$ is invariant under $\sigma$ and hence real-valued, it must be that $\tau^2(x) \sigma(x)$ is complex-valued which contradicts the previous result. Hence, (45) is false and there exists no $A \in A$ such that $A^2(A) = A^3(A) = i$.

APPENDIX G

PROOF OF PROPOSITION 6

Let $A = a + j b$, $a, b \in \mathbb{Q}(\omega, \theta)$ such that

$$A^2 = \cdots = A^3 = -\omega.$$ \hspace{1cm}  (50)

Applying $T^3$ throughout (50), we observe that $A^2(A)^2 = A^3(A)$ and $A^3(A)^3(A) = 1$. Let $A^3(A) = x + j y$ where $x = a \tau(a) - \sigma(y) \tau(b)$, $y = y \tau^2(a) + \sigma(x) \tau^2(b)$ with $x' = a \tau(a) - \sigma(b) \tau(b)$, $y' = b \tau(a) + \sigma(a) \tau(b)$. So, we have

$$(x + j y)(\tau^3(x) + j \tau^3(y)) = (\tau^3(x) + j \tau^3(y))(x + j y)$$

from which we obtain

$$y \tau^3(x) + \sigma(x) \tau^3(y) = \sigma \tau^3(x) y + x \tau^3(y).$$ \hspace{1cm}  (51)

From (50), we obtain

$$x \tau^3(x) - \sigma(y) \tau^3(y) = -\omega$$ \hspace{1cm}  (52)

$$\sigma(x) \tau^3(y) + y \tau^3(x) = 0.$$ \hspace{1cm}  (53)

Now, if $x = 0,$

$$\sigma(y) \tau^3(y) = \omega.$$ \hspace{1cm}  (54)

By applying $\sigma$ and $\tau^3$ separately throughout (54), we obtain

$y \sigma \tau^3(y) = -\omega^2$ (for $\sigma(\omega) = \omega^2$) and $y \sigma \tau^3(y) = \omega$, which contradict each other. Hence, $x \neq 0$. On the other hand, if $y = 0$, then $x \tau^3(x) = -\omega$ and therefore, $\tau(x) \tau^3(x) = -\omega, \tau^2(x) \tau^3(x) = -\omega$. Using these results, we arrive at

$$x \tau^3(x) \left[ (\tau(x) \tau^3(x)) \left( \tau^2(x) \tau^3(x) \right) \right] = (-\omega)^3 = -1.$$  \hspace{1cm}  (55)

Since $x \in \mathbb{Q}(\omega, \theta), (55)$ implies that there exists some $x \in \mathbb{Q}(\omega, \theta)$ such that $N_{Q(\omega, \theta)/Q(\omega)}(x) = -1$. This is not true since $(-\omega)^i$ is not a norm of any field element of $\mathbb{Q}(\omega, \theta)$ for $t = 1, 2, 3, 4$. Hence, we can assume that $x, y \neq 0$. Using (51) and (53), we get

$$\frac{\sigma \tau^3(x)}{\sigma(x)} = \sigma \frac{\tau^3(x)}{\sigma(x)}$$

so that $\sigma \frac{\tau^3(x)}{\sigma(x)} = \sigma \frac{\tau^3(x)}{\sigma(x)}$. Therefore, $\sigma \frac{\tau^3(x)}{\sigma(x)}$ is real-valued and belongs to $\mathbb{Q}(\theta)$. Now, using (53) in (52), we get

$$\sigma(x) \left[ x \sigma(x) + y \sigma(y) \right] = \omega.$$  \hspace{1cm}  (56)

Since $x \sigma(x) + y \sigma(y)$ is invariant under $\sigma$ and hence real-valued, $\sigma \frac{\tau^3(x)}{\sigma(x)}$ has to be complex-valued which contradicts the previous result. Hence, (50) is false and there exists no $A \in A$ such that $A^2(A) = A^3(A) = \cdots = A^5(A) = -\omega$.

ACKNOWLEDGEMENTS

The authors thank Dr. Nadya Markin for useful discussions on the topic.

[35] K. P. Srinath and B. S. Rajan, “Improved Perfect Space-Time Block Codes”, to appear in the IEEE Trans. Inf. Theory.

K. Pavan Srinath received the B. E. degree in Electronics and Communica tion Engineering from B. M. Sreenivasiahal College of Engg., Bangalore, India, the M. E. and PhD degrees in Electrical and Communication Engineering from the Indian Institute of Science, Bangalore, in 2005, 2008, and 2013, respectively. From September 2005 to June 2006, he was with Robert Bosch India limited, Bangalore. Currently, he is a research engineer in Broadcom Communication Technologies Pvt. Ltd., Bangalore. His primary research interests include wireless communication, space-time coding and coding for wireless relay networks.

B. Sundar Rajan (S’84-M’91-SM’98) was born in Tamil Nadu, India. He received the B.Sc. degree in mathematics from Madras University, Madras, India, the B.Tech degree in electronics from Madras Institute of Technology, Madras, and the M.Tech and Ph.D. degrees in electrical engineering from the Indian Institute of Technology, Kanpur, in 1979, 1982, 1984, and 1989 respectively. He was a faculty member with the Department of Electrical Engineering at the Indian Institute of Technology in Delhi, from 1990 to 1997. Since 1998, he has been a Professor in the Department of Electrical Communication Engineering at the Indian Institute of Science, Bangalore. His primary research interests include space-time coding for MIMO channels, distributed space-time coding and cooperative communication, coding for multiple-access and relay channels, and network coding.

Dr. Rajan is presently an Editor of the IEEE WIRELESS COMMUNICATIONS LETTERS and an Associate Editor of Coding Theory for IEEE TRANSACTIONS ON INFORMATION THEORY. He was an Associate Editor of the IEEE TRANSACTIONS ON INFORMATION THEORY (2008-2011) and an Editor of the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS (2007-2011). He served as Technical Program Co-Chair of the IEEE Information Theory Workshop (ITW’02), held in Bangalore, in 2002. He is a Fellow of Indian National Academy of Engineering, a Fellow of the Indian National Science Academy, a Fellow of the Indian Academy of Science, a Fellow of the National Academy of Sciences, India, recipient of Prof. Rustum Choksi award by I.I.Sc for excellence in research in Engineering for the year 2009, recipient of the IETE Pune Center’s S.V.C. Aiyar Award for Telecom Education in 2004, and recipient of Best Academic paper award at the IEEE WCNC 2011. Also, Dr. Rajan is a Member of the American Mathematical Society.
