We test the holographic relation between the vacuum expectation values of gauge invariant operators in $\mathcal{N} = 6$ $U_k(N) \times U_{-k}(N)$ mass-deformed ABJM theory and the LLM geometries with $\mathbb{Z}_k$ orbifold in 11-dimensional supergravity. To do that, we apply the Kaluza-Klein reduction to construct a 4-dimensional gravity theory and implement the holographic renormalization procedure. We obtain an exact holographic relation for the vacuum expectation values of the chiral primary operator with conformal dimension $\Delta = 1$, which is given by $\langle O^{(\Delta=1)} \rangle = N^{\frac{k}{2}} f_{(\Delta=1)}$, for large $N$ and $k = 1$. Here factor $f_{(\Delta)}$ is independent of $N$. Our results involve infinite number of exact dual relations for all possible supersymmetric Higgs vacua and so provide a nontrivial test of gauge/gravity duality away from the conformal fixed point. We also extend our results to the case of $k \neq 1$ for LLM geometries represented by rectangular-shaped Young-diagrams.

I. INTRODUCTION

In the context of the AdS/CFT correspondence [1–3], it was conjectured that the string/M theory on $\text{AdS}_{d+1} \times X$ with a compact manifold $X$ is dual to $d$-dimensional conformal field theory (CFT). The conjecture was soon extended to quantum field theories (QFTs) which can be obtained from the CFTs at the Ultraviolet (UV) fixed point by adding relevant operators to the action or considering vacua where the conformal symmetry is broken. Then the dual geometries for those QFTs are asymptotic to $\text{AdS}_{d+1} \times X$. Due to computational difficulties on both sides, most of the efforts to test the duality have been focused on the large $N$ limit of the QFT, $N$ being the rank of the gauge group.

In this letter, we analyze a model which shows a promising evidence for an exact dual relation away from the conformal fixed point in the large $N$ limit. We consider the $\mathcal{N} = 6$ $U_k(N) \times U_{-k}(N)$ Aharony-Bergman-Jafferis-Maldacena (ABJM) theory with Chern-Simons level $k \neq 1$, as the CFT at the UV fixed point. The ABJM theory allows the supersymmetry preserving mass deformation and the deformed theory (mABJM) [4, 5] has discrete Higgs vacua presented by the Gonis, Rodriguez-Gomez, Van Raamsdonk, Verlinde (GRVV) matrices [6]. It was known that the vacua of the mABJM theory have one-to-one correspondence [7, 8] with the half BPS Lin-Lunin-Maldacena (LLM) geometries [9, 10] with $\mathbb{Z}_k$ orbifold having $SO(2,1) \times SO(4)/\mathbb{Z}_k \times SO(4)/\mathbb{Z}_k$ isometry in 11-dimensions [8, 11]. Since the mABJM theory is obtained by a relevant deformation from the ABJM theory at the UV fixed point, the dual geometry should be asymptotically $\text{AdS}_4 \times S^7/\mathbb{Z}_k$.

Here we test the above gauge/gravity duality. In field theory side, we calculate the vacuum expectation values (vevs) of the chiral primary operator (CPO) with conformal dimension $\Delta = 1$ for all possible supersymmetric vacua of the mABJM theory with any $k$. In gravity side, we implement the Kaluza-Klein (KK) reduction on $S^7$ and construct 4-dimensional quadratic action from 11-dimensional supergravity on the $\text{AdS}_4 \times S^7$ background. Applying holographic renormalization method [12], we obtain an exact holographic relation for the vevs of the CPO with $\Delta = 1$, which is given by $\langle O^{(\Delta=1)} \rangle = N^{\frac{k}{2}} f_{(\Delta=1)}$. Here we consider $k = 1$ case and $f_{(\Delta)}$ is a function of the conformal dimension and also depends on some parameters of LLM solutions [10]. This result is extended to $k > 1$ for specific types of LLM solutions.

II. DISCRETE HIGGS VACUA AND DUAL GEOMETRIES

The SU(4) global symmetry of the ABJM theory is broken to $\text{SU}(2) \times \text{SU}(2) \times U(1)$ symmetry under the supersymmetry preserving mass deformation [5, 9]. To manifest the broken symmetry, we split the scalar fields into $Y^A = (Z^a, W^{1a})$, where $A = 1, 2, 3, 4$ and $a = 1, 2$. Then the Higgs vacua of the mABJM theory are represented as direct sums of irreducible $n \times (n + 1)$ GRVV matrices [6]. $M^{(n)}_a$ with the occupation number $N_n$, and their Hermitian conjugates $(n + 1) \times n$ matrices $M^{(n)}_a$ with $N'_n$ [8]. (See also [13] for the vacuum solutions.) Since $Z^a$ and $W^{1a}$ are $N \times N$ matrices, we have two constraints, $\sum_{n=0}^{\infty} \left( n + \frac{1}{2} \right) (N_n + N'_n) = N$ and
\[ \sum_{n=0}^{\infty} N_n = \sum_{n=0}^{\infty} N'_n. \] In addition, in order to have supersymmetric vacua the range of the occupation numbers should be \( 0 \leq N_n, N'_n \leq k \). As a result, the supersymmetric vacua of the mABJM theory are completely classified in terms of the occupation numbers, \( \{N_n, N'_n\} \).

The LLM geometry with \( Z_k \) orbifold is determined by two functions \( Z \) and \( V \),

\[
Z(\tilde{x}, \tilde{y}) = \sum_{i=1}^{2N_B+1} \frac{(-1)^{i+1}(\tilde{x} - \tilde{x}_i)}{2\sqrt{\tilde{x} - \tilde{x}_i^2 + \tilde{y}^2}},
\]

\[
V(\tilde{x}, \tilde{y}) = \sum_{i=1}^{2N_B+1} \frac{(-1)^{i+1}}{2\sqrt{\tilde{x} - \tilde{x}_i^2 + \tilde{y}^2}}, \tag{1}
\]

where \( \tilde{x} \) and \( \tilde{y} \) are 11-dimensional coordinates, \( \tilde{x}_i \)'s the positions of boundaries of black and white strips in the droplet picture \([10]\), and \( N_B \) is the number of finite black droplets. Due to the quantization condition of the 4-form flux, the difference between consecutive \( \tilde{x}_i \)'s is quantized as \( \tilde{x}_{i+1} - \tilde{x}_i = 2\pi i \mu_0 Z \) with the Planck length \( l_P \) and the mass parameter \( \mu_0 \). This implies that all possible LLM geometries are parametrized by the quantized \( \tilde{x}_i \)'s. For the asymptotic expansion of the LLM geometries, it is convenient to introduce new parameters \([14]\),

\[
C_p = \sum_{i=1}^{2N_B+1} (-1)^{i+1} \left( \frac{\tilde{x}_i}{2\pi l_P^3 \mu_0 \sqrt{A}} \right)^p, \tag{2}
\]

where \( A = kN - \frac{1}{2} \sum_{n=0}^{\infty} l_n(k - l_n) + l'_n(k - l'_n) \) is the area of the Young diagram picture and \( \{l_n, l'_n\} \) set of parameters classifying the LLM geometries in the droplet picture. See \([8]\) for the details. There is one-to-one correspondence between \( \{l_n, l'_n\} \) and the occupation numbers \( \{N_n, N'_n\} \) in the vacua of the mABJM theory \([8]\).

## III. KALUZA-KLEIN HOLOGRAPHY

In order to implement the KK holography method \([13-17]\), we consider asymptotic expansion of the LLM geometries with \( Z_k \) orbifold and regard the deviation from AdS4 \( \times S^7/Z_k \) geometry as solutions to perturbed equations of motion in 11-dimensional supergravity on such background. According to the dictionary of the gauge/gravity duality \([2,3]\), the deviations in asymptotic limit encode the information of vevs of CPOs \([8]\) in the mABJM theory.

Our purpose in this letter is to compare quantitatively the vevs of CPOs in the mABJM theory with the corresponding asymptotic coefficients of KK scalar fields, based on the KK holographic procedure \([13-17]\). Since the elements of the GRVV matrices are real numbers, one can compute the vevs of CPOs in terms of numerical values and compare them with the corresponding coefficients of the KK scalars in gravity side. The number of supersymmetric vacua is numerous for a given \( N \) and thus large number of nontrivial tests can be carried out.

More precisely, the vev of CPO with conformal dimension \( \Delta \) is proportional to the coefficient of \( z^\Delta \)-term in the asymptotic expansion of the dual scalar field in gravity side \([13]\), where \( z \) represents the coordinate in holographic direction. When we restrict our interest to the CPOs with low conformal dimensions, it is sufficient to consider the dual LLM geometry near the asymptotic limit.

In particular, the vevs of CPOs with \( \Delta = 1 \) are holographically determined by the solutions of the linearized supergravity equations of motion on the AdS4 \( \times S^7/Z_k \) background. In this case, diagonalized gauge invariant fields in 11-dimensions can be identified with 4-dimensional gravity fields without nontrivial field redefinitions. However, for \( \Delta \geq 2 \), nonlinear terms in the equations of motion are not negligible and nontrivial field redefinitions in the construction of the 4-dimensional gravity theory are necessary \([12]\). In this letter we focus on the CPO with \( \Delta = 1 \) and leave our study on CPOs with \( \Delta \geq 2 \) as future work.

### A. Field theory side

The CPO with conformal dimension \( \Delta \) in the ABJM theory is

\[
\langle O(\Delta) \rangle = C^{B_1,\cdots,B_\Delta}_1,\cdots,\Delta_1 \text{Tr}(Y^{A_1} Y^{T_1} \cdots Y^{A_\Delta} Y^{T_\Delta}), \tag{3}
\]

where the coefficients, \( C^{B_1,\cdots,B_\Delta}_1,\cdots,\Delta_1 \), are symmetric in upper as well as lower indices and traceless over one upper and one lower indices. The CPO in \([3]\) is written by reflecting the global SU(4) symmetry of the ABJM theory. On the other hand, in the mABJM theory the CPO should reflect the SU(2)\( \times SU(2)\times U(1) \) global symmetry, of which the explicit form will be given later.

For a given vacuum, the complex scalar fields near the vacuum are written as \( Y^A(x) = Y^A_0 + \tilde{Y}^A \), where \( Y^A_0 \)'s \((A = 1, 2, 3, 4)\) are the vacuum solutions represented by GRVV matrices, and \( \tilde{Y}^A \)'s are field operators. Then the vev of a CPO with dimension \( \Delta \) for a specific vacuum in the mABJM theory is given by

\[
\langle O(\Delta) (Y^A) \rangle_m = \langle O(\Delta) (Y^A_0) \rangle + \langle \delta O(\Delta) (\tilde{Y}^A) \rangle_0 + \frac{1}{N} \text{ corrections}, \tag{4}
\]

where \( \langle \cdots \rangle_m \) and \( \langle \cdots \rangle_0 \) denote the vevs in the mABJM theory and the ABJM theory, respectively. The \( \frac{1}{N} \) corrections come from the contributions of multi-trace terms \([19-21]\). Here we note that quantum corrections of scalar fields are absent due to the high supersymmetry of the mABJM theory. The second term in the above equation is a one point function in a conformal field theory and is vanishing. Therefore, in the large \( N \) limit we have

\[
\langle O(\Delta) (Y^A) \rangle_m = \langle O(\Delta) (Y^A_0) \rangle. \tag{5}
\]
The vacua parametrized by the occupation numbers \( \{N_n, N_n^*\} \) of the GRVV matrices are composed of \( N \times N \) matrices having numerical matrix components. Therefore, the resulting vev \( \langle O^{(\Delta)} \rangle \) is a numerical value for a given \( N \). We compare the specific value of vev with the corresponding asymptotic coefficient in gravity side.

### B. Gravity side

We start with \( k = 1 \) case and write the fluctuations of 11-dimensional supergravity fields on the AdS\(_4 \times S^7 \) background as

\[
g_{pq} = g^0_{pq} + h_{pq}, \quad F_{pqr} = F^0_{pqr} + f_{pqr},
\]

where \( g^0_{pq} \) and \( F^0_{pqr} \) represent the background geometry. To construct the 4-dimensional gravity theory, we implement KK reduction on \( S^7 \). This reduction involves the expansion of the fluctuations in (6) in terms of \( S^7 \) spherical harmonics. The expansion is generally expressed in terms of scalar, vector, and tensor spherical harmonics. The expansion is generally expressed in terms of scalar spherical harmonics. The expansion is generally expressed in terms of scalar spherical harmonics.

Here the truncated expansion involving only the scalar spherical harmonics is given,

\[
h_{\mu \nu}(x, y) = h^{I_1}_{\mu \nu}(x)Y^{I_1}(y), \quad h_{\alpha \beta}(x, y) = s^I_{\alpha \beta}(x)\nabla_\alpha Y^{I_1}(y),
\]

\[
h^a_{\alpha \beta}(x, y) = \varphi^{I_1}(x)Y^{I_1}(y),
\]

\[
f_{\mu \nu \rho \sigma}(x, y) = 4\nabla_\mu s^I_{\nu \rho \sigma}(x)Y^{I_1}(y),
\]

\[
f^a_{\mu \nu \rho \sigma}(x, y) = -s^I_{\mu \nu \rho \sigma}(x)\nabla_\alpha Y^{I_1}(y),
\]

where \( I_1 \) is non-negative integer, \( x \) denotes the AdS\(_4 \) coordinates, \( y \) the \( S^7 \) coordinates, and we divide the 11-dimensional indices \( p, q, \ldots \) into the indices of AdS\(_4 \), \( \mu, \nu, \ldots \), and those of \( S^7 \), \( a, b, \ldots \). The notation \( [ab] \) is for symmetrized traceless combination, while the notation \( [ \alpha \beta \gamma \cdots ] \) is for anti-symmetrization among the indices, \( a, b, \cdots \). The scalar spherical harmonic \( Y^{I_1} \) is determined by the eigenvalue equation,

\[
\left[ \nabla_\alpha \nabla^\alpha + \frac{I_1(I_1 + 6)}{L^2} \right] Y^{I_1} = 0,
\]

where \( L = (32\pi^2 kN)^{1/6} \) is the radius of \( S^7 \). The expansion (7) follows the convention of [15, 23]. See also [24] for the linearized equations of motion on AdS\(_4 \times S^7 \) background in de Donder gauge.

Plugging (7) into the linearized equations of motion on the AdS\(_4 \times S^7 \) background and collecting relevant equations of motion, we obtain two diagonalized equations for KK scalar fields in 4-dimensions (see [22] for details),

\[
\left[ \nabla_\mu \nabla^\mu - \frac{(I_1 + 6)(I_1 + 12)}{L^2} \right] \Phi^{I_1}(x) = 0,
\]

\[
\left[ \nabla_\mu \nabla^\mu - \frac{I_1(I_1 - 6)}{L^2} \right] \Psi^{I_1}(x) = 0,
\]

where

\[
\Phi^{I_1} = \frac{(I_1 + 7)}{14(I_1 + 3)} \left[ 18(I_1 - 1)\phi^{I_1} + 7\psi^{I_1} \right],
\]

\[
\Psi^{I_1} = \frac{(I_1 - 1)}{14(I_1 + 3)} \left[ -18(I_1 + 7)\phi^{I_1} + 7\psi^{I_1} \right]
\]

with gauge invariant combinations,

\[
\phi^{I_1} = \phi^{I_1} + \frac{I_1(I_1 + 6)}{L^2} \psi^{I_1},
\]

\[
\psi^{I_1} = 18\delta^0_{\mu \nu} h^{I_1}_{\mu \nu} - L\epsilon^{\mu \nu \rho \sigma} \nabla_\rho s^I_{\sigma \theta \varphi}.
\]

In the subsequent discussion, we will expand the LLM solution as in (6) and read the corresponding values of \( \Phi^{I_1} \) and \( \Psi^{I_1} \).

### IV. Exact holography

In mABJM theory, the CPO defined in (3) is constrained by the SU(2) \( \times \) SU(2) \( \times \) U(1) global symmetry. In particular for the \( \Delta = 1 \) case, we have

\[
\langle \mathcal{O}^{(1)} \rangle = \frac{1}{2\sqrt{2}} \text{Tr} \left( Z_a Z^a_0 - W^a_0 W_a \right),
\]

where the overall numerical factor is determined by the normalization condition, \( C^{(1)}_{A_1 \cdots A_\Delta} C^{(1)}_{A_1 \cdots A_\Delta} + (c.c.) = \delta^{I J} \). We have verified that all CPOs with \( \Delta = 1 \) except for \( \mathcal{O}^{(1)} \) in (11) have vanishing vevs for all supersymmetric vacua of the mABJM theory.

Plugging (11) into (10) and expressing vevs in terms of the GRVV matrices, we obtain

\[
\langle \mathcal{O}^{(1)} \rangle_m = \frac{\kappa \mu}{4\sqrt{2\pi}} \sum_{n=0}^{2N + 1} n(n + 1)(N_n - N_n^*). \tag{12}
\]

Here \( \mu \) is the mass parameter in the mABJM theory and has the relation \( \mu = 4\mu_0 \) with the mass parameter \( \mu_0 \) in the LLM geometries.

The LLM geometries near the asymptotic limit can be regarded as AdS\(_4 \times S^7/Z_k \) plus small fluctuations. Though the gauge conditions of the LLM solutions in 11-dimensional supergravity are not clear, the 4-dimensional fields \( \Phi^{I_1} \) and \( \Psi^{I_1} \) in (10) are gauge invariant and can be read from the asymptotic expansions. According to the holographic dictionary, asymptotic coefficients of \( \Phi^{I_1} \) and \( \Psi^{I_1} \) encode the vevs of the corresponding CPOs in the mABJM theory.

Warp factors in the LLM geometries [10] are completely fixed by \( Z \) and \( V \) in (11), which are functions of \( \hat{x} \) and \( \hat{y} \). To implement the holographic renormalization procedure [12], we should rewrite the LLM solution in terms of the Fefferman-Graham (FG) coordinate system,

\[
d s^2_{\text{FG}} = g_1(z, \tau) (-dt^2 + dw_1^2 + dw_2^2) + \frac{L^2}{4z^2} dz^2 + g_2(z, \tau) d\tau^2 + g_3(z, \tau) ds^2_{S^3} + g_4(z, \tau) ds^2_{S^3},
\]
where $z$ is the holographic direction and $\tau$ is one of the $S^7$ coordinates in the asymptotic limit. For a general droplet parametrized by the $C_I$’s in [2], the asymptotic expansion of these warp factors gives
\[
\begin{align*}
g_1 &= \frac{L^2}{4z^2} \left[ 1 - \frac{2\tau \beta_3}{3\sqrt{2}} \mu_0 z + O(\mu_0^2) \right], \\
g_2 &= \frac{L^2}{4(1 - \tau^2)} + O(\mu_0^2), \\
g_3 &= \frac{L^2(1 + \tau)}{2} \left[ 1 + \frac{(1 + \tau)\beta_3}{3\sqrt{2}} \mu_0 z + O(\mu_0^2) \right], \\
g_4 &= \frac{L^2(1 - \tau)}{2} \left[ 1 - \frac{(1 - \tau)\beta_3}{3\sqrt{2}} \mu_0 z + O(\mu_0^2) \right]
\end{align*}
\] (14)
with $\beta_3 = 2C_1 - 3C_2 + C_3$. From the asymptotic expansion of the warp factors and a similar expansion for the 4-form flux [22], one can read fluctuations in [3], which will later be used in the construction of the modes $\Phi^{I_1}$ and $\Psi^{I_1}$.

We need to express the LLM geometries in terms of the spherical harmonics on $S^7$. Since the geometries have SO(4)$\times$SO(4) isometry, they can be appropriately expressed in terms of the spherical harmonics having the same isometry. The scalar spherical harmonics on $S^7$ are defined by the eigenvalue equation [3]. In $\mu_0 z \to 0$ limit the warp factors in [13] depend only on the $\tau$ coordinate, and thus the appropriate spherical harmonics are the solutions of [3] which also depends only on $\tau$ coordinate. One obtains two kinds of such solutions represented by the hypergeometric function $2F_1(a, b; c; \tau^2)$, which correspond to those with $I_1 = 4i$ and $I_1 = 4i + 2$, ($i = 0, 1, 2, \cdots$). First few nonvanishing $Y^{I_1}$’s are given by
\[
Y^0 = 1, \quad Y^2 = \frac{\tau}{\sqrt{2}}, \quad Y^4 = \frac{1 - 5\tau^2}{8\sqrt{10}}, \quad \cdots,
\] (15)
where we used the normalization $\frac{3}{\pi^2} \int Y^{I_1} Y^{J_1} = \frac{3L^2\delta^{I_1 J_1}}{2^{I_1 + 1}(I_1 + 3)}$.

According to the dictionary of gauge/gravity duality, the mass of scalar mode is related to the conformal dimension $\Delta$ of the corresponding operator. In AdS$_4$/CFT$_3$ correspondence the relation is
\[
m^2 L^2_{\text{AdS}_4} = \frac{n^2 L^2}{4} = \Delta(\Delta - 3).
\] (16)
From [9] we see that the masses of the 4-dimensional scalar modes have the form $m^2 = n(n - 6)/L^2$ with $n = I_1 + 12$ for $\Phi^{I_1}$ and $n = I_1$ for $\Psi^{I_1}$, respectively. So the relation (16) is rewritten as $n(n - 6) = 4\Delta(\Delta - 3)$. From this relation the scalar mode $\Phi^{I_1}$ satisfying the relation $(I_1 + 12)(I_1 + 6) = 4\Delta(\Delta - 3)$ can not be the dual scalar field of the CPO with $\Delta = 1$. On the other hand, we notice that the field $\Psi^{I_1}$ satisfies the relation $I_1(I_1 - 6) = 4\Delta(\Delta - 3)$, which implies $\Delta = \frac{5}{4}$. We naturally expect that the dual scalar field for the CPO with $\Delta = 1$ in [11] is nothing but $\Psi^{I_1}$ in [10] with $I_1 = 2$.

By writing the asymptotic expansion of the LLM geometries [14] in terms of the scalar spherical harmonics [15], we obtain the asymptotic behavior of the 4-dimensional scalar modes, $\Phi^{I_1}$ and $\Psi^{I_1}$ with $I_1 = 2$,
\[
\Phi^{I_1 = 2} = O(\mu_0^3), \quad \Psi^{I_1 = 2} = -24\beta_3 \mu_0 z + O(\mu_0^2).
\] (17)

According to the holographic renormalization procedure for the scalar action on the AdS$_4$ background, we have
\[
\langle O^{(1)} \rangle_m = \frac{N^2}{\sqrt{\lambda}} \mu_0 \langle \psi^{(1)} \rangle = -\frac{24N^2}{\sqrt{\lambda}} \mu_0 \beta_3,
\] (18)
where $N$ is a numerical number depending on the normalization of the scalar $\Psi^{I_1 = 2}$, $\psi^{(1)}$ is the coefficient of the radial coordinate $z$ in the expansion of the scalar mode, and $\lambda$ is the ’t Hooft coupling constant defined as $\lambda = N/k$ in ABJM theory. In the case $k = 1$, the overall normalization in [15] is reduced to $N^\frac{2}{3}$. The $N^\frac{2}{3}/\sqrt{\lambda}$ dependence in the right-hand side of (18) is a peculiar behavior of the normalization factor in holographic dual relation for the M2-brane theory [4, 25, 26]. By identifying the occupation number of vacua in the mABJM theory with the discrete torsion in the LLM geometries [8], i.e.,
\[
\{N_n, N'_n\} \leftrightarrow \{l_n, l'_n\},
\] (19)
the normalization factor $N$ is fixed.

Comparing the values in (12) in $k = 1$ field theory with the corresponding values of $\beta_3$ in gravity side, we obtain an exact holographic relation,
\[
\langle O^{(1)} \rangle_m = \frac{N^\frac{2}{3} \mu_0}{3\sqrt{2}\pi} \beta_3
\] (20)
with the numerical normalization factor $N = -\frac{\sqrt{7}}{144\pi}$. In Young-diagram picture of the LLM geometries, $\beta_3$ has no dependence on $N$ and depends only on the shape of Young-diagrams and is independent of the size of the diagram. To prove the holographic relation (20), we used the relations, (12) and (19), and the following identity,
\[
\sum_{n=0}^{2N_{A+1}} n(n + 1)(l_n - l'_n) = \frac{1}{3} \left( 2\tilde{C}_3 - 3\tilde{C}_1 \tilde{C}_2 + \tilde{C}_3 \right),
\] where $\tilde{C}_p = A^\frac{7}{2} C_p$, $A$ being the area of the Young-diagram in [2]. Interestingly, the relation (20) in the leading $N$ behavior is exactly satisfied for all $N \geq 2$. Technical details for the proof will be reported in a separate paper [22].

We also obtain the normalization factor $N$ for $k \neq 1$ with $N_B = 1$. In the Young-diagram picture, this corresponds to the rectangular-shaped diagrams. For this case the exact dual relation is given by
\[
\langle O^{(1)} \rangle_m = \frac{N\sqrt{kN}\mu_0}{3\sqrt{2}\pi} \beta_3 = \frac{N\sqrt{NN\mu_0}}{3\sqrt{2}\pi} \sqrt{\lambda} \beta_3,
\] (21)
where $\tilde{N} = A/k$ and $\lambda = N/k$ is ’t Hooft coupling constant in the ABJM theory. In the large $N$ limit, $\tilde{N}$ approaches $N$ and the overall factor $N^2/\sqrt{\lambda}$ in \cite{17} appears. For $k = 1$, the holographic relation \cite{21} reduces to the result in \cite{20}.

\section{Conclusion}

In this letter, we carried out the KK reduction and the holographic renormalization procedure for the mABJM theory and the LLM geometry in 11-dimensional supergravity. By calculating the vevs of CPO with $\Delta = 1$ in field theory side and the corresponding asymptotic coefficients in gravity side, we found a supporting evidence for an exact gauge/gravity duality with $k = 1$ in the large $N$ limit. We could test the duality since discrete Higgs vacua exist in the mABJM theory and they correspond one-to-one with the LLM geometries. We also extended the exact holographic relation to the case of any $k$ for LLM geometries represented by rectangular-shaped Young-diagrams.

It seems that the Higgs vacua of the mABJM theory are parametrized by the vevs of CPOs and those are non-renormalizable due to the high supersymmetry. This is similar to the case of the Coulomb branch in large $N$ limit in $\mathcal{N} = 4$ super Yang-Mills theory \cite{15,16}. Though our quantitative results for the gauge/gravity correspondence involve infinite examples, we need to accumulate more analytic evidences for CPOs with $\Delta (\geq 2)$ and $k (\geq 1)$ to define supersymmetric vacua. One should also test the dictionary of the gauge/gravity duality for one point functions of vector and tensor fields. For instance, it is important to verify that one point functions of the energy-momentum tensor vanish for all possible supersymmetric vacua, since the mABJM theory is a supersymmetric theory. We leave these issues for future study.

One necessary condition of the supergravity approximation in AdS/CFT correspondence is the large $N$ limit. It was reported recently that the dual gravity limit of the ABJM theory is broken down at the sub-leading order of $N$ due to one-loop quantum correction \cite{22}. Therefore, though our results suggest that the LLM geometries can be well-defined backgrounds in the point of the gauge/gravity duality, fluctuations on those backgrounds can go beyond the supergravity approximation. We need more investigation in this direction.

Recently, it was reported that the mABJM theory on $S^3$ has no gravity dual for the mass parameter larger than a critical value \cite{28} (see also \cite{29,31}). Though the setup is different from ours, which is the mABJM theory on $R^{2,1}$, it is also intriguing to investigate the large mass region for our case. It seems promising to pursue this issue since the LLM geometries have no singularity over the whole transverse region.
