Activating Fcγ receptors associated with Fc receptor γ-chain (FcRγ) are critical for mediating neutrophil effector functions in immune complex-mediated autoimmune diseases. FcRγ contains ITAM tyrosines and the in vivo role of these tyrosines has not been defined in neutrophils and arthritis. In this study, the in vivo functions of FcRγ ITAM tyrosines were characterized using wild type and ITAM tyrosine mutant (Y65F/Y76F) transgenic mice crossed to an FcRγ-deficient genetic background. FcRγ-deficient neutrophils showed undetectable cell surface expression of the activating Fcy receptor IV, defective immune complex-induced superoxide production, degranulation and spreading. Although the re-expression of both the wild type and the ITAM tyrosine mutant (Y65F/Y76F) FcRγ could restore activating Fcy receptor expression of FcRγ-deficient neutrophils, only the wild type transgenic form could mediate Fcy receptor-dependent effector functions. In contrast, neutrophils carrying ITAM tyrosine mutant FcRγ were unable to produce superoxide, mediate degranulation and perform active spreading. In addition, our results confirmed the protection of FcRγ-deficient mice from autoimmune arthritis. Importantly, the presence of the wild type FcRγ transgene, in contrast to the ITAM tyrosine mutant transgene, partially reversed autoimmune arthritis development. The reversing effect of the wild type transgene was even more robust when animals carried the wild type transgene in a homozygous form. Collectively, FcRγ ITAM tyrosines play a critical role in the induction of neutrophil effector responses, the initiation and progression of an autoantibody-induced experimental arthritis in vivo, indicating a signaling, rather than just a receptor stabilizing function of the molecule.

Keywords: neutrophils, Fc receptor γ-chain, ITAM tyrosines, autoimmune arthritis, Fc receptors

INTRODUCTION

Activating Fcγ receptors expressed on the surface of neutrophils are critical for mediating various cellular responses including immune complex-triggered cellular activation, clearance of immune complexes and phagocytosis of opsonized particles (1–3). These processes are involved in the pathogenesis of various autoimmune diseases including rheumatoid arthritis (2–4).
Resting human neutrophils express the activating Fc receptors FcγRIIA and FcγRIIB, while FcγRI appears upon stimulation (5). While the single chain transmembrane FcγRIIA contains an immunoreceptor tyrosine-based activation motif (ITAM) in the cytoplasmic tail of the molecule, FcγRI is associated with an ITAM-bearing transmembrane adapter protein called Fc receptor y-chain (FcRy). In addition, the GPI-anchored FcγRIIB is also present on the surface of human neutrophils. This molecule does not contain an ITAM-motif and is not associated with an ITAM-bearing adapter side chain; according to the current view it is functionally connected to FcγRIIA (5, 6).

Murine neutrophils express a different set of activating Fc receptors including two low affinity (FcγRIIa and FcγRIIb) and one high affinity (FcγRI) Fcγ receptors, all of which are associated with the ITAM-containing FcγR (5). Our previous findings indicated the critical but overlapping role of FcγRIIa and FcγRIIb in immune complex-dependent neutrophil activation (6). Subsequent in vivo studies revealed the importance of FcγRIIa and FcγRIIb for the development and progression of autoantibody-induced arthritis and autoimmune valvular carditis in the K/BxN serum transfer experimental model (5, 7).

As discussed above, all activating murine Fcγ receptors form a complex with FcγR, which molecule does not contain a ligand binding domain (1). It is known that the lack of FcγR abrogates the cell surface expression of activating Fcγ receptors and FcγR-deficiency leads to abolished Fc receptor-dependent neutrophil effector responses and protection from autoimmune arthritis (6, 9-13). However, due to the absence of the cell surface expression of activating Fcγ receptors in FcRγ-deficient mice, it remains unclear whether the sole function of FcRγ is to enable the receptor expression or it is also actively involved in the signaling process through its ITAM tyrosines.

In prior in vitro structure-function studies, the role of ITAM tyrosine phosphorylation was demonstrated in serotonin secretion in a basophilic cell line suggesting the signaling function of FcγR ITAM tyrosines (14). It was also reported that the phosphorylation of the ITAM tyrosines is induced by the FcγR-associated FceR stimulation in mast cells (15).

The functional role of these ITAM tyrosines was characterized using FcγRγ-deficient mice reconstituted with murine wild type and ITAM tyrosine mutant (Y65F/Y67F) transgenes. These findings suggested that the ITAM tyrosines are involved in degranulation, cytokine production, prostaglandin synthesis and passive systemic anaphylaxis in mast cells (16). In another genetic model for in vivo studies, human transgenic FcγR γ was expressed carrying mutated ITAM tyrosines on an FcγRγ-deficient genetic background (NOTAM mice) (17). While the surface expression of Fc receptors was not affected, the in vivo cytotoxicity critically depended on FcγR ITAM signaling (17). The uptake of immune complexes and the cross presentation of antigens was reported to be regulated by FcγR ITAM signaling in dendritic cells, while MHC class II antigen presentation was ITAM-independent (18).

In contrast to the first two reports suggesting the functions of FcγR ITAM tyrosines, recent mouse studies revealed that daratumumab, which is a monoclonal therapeutic antibody targeting CD38 that is highly expressed on the surface of some kinds of tumor cells, induces cancer cell death after its binding, which process occurs in NOTAM but not in FcγRγ-deficient mice after blocking FcγRIIB (19). In addition, Lehmann et al. showed that engineered chimeric antibodies instructed splenic dendritic cells to activate CD4- and CD8-positive T-cells through the FcγRγ-coupled FcγR IV without the involvement of the ITAM tyrosines (20). Collectively, these recent reports indicated the existence of ITAM-independent in vivo functions of FcγRγ-coupled activating Fc receptors (19, 20). Therefore, further studies are needed to define the in vivo role of FcγR ITAM tyrosines.

Upon Fc receptor-stimulation of neutrophils, FcγR was reported to be phosphorylated and to recruit the Syk tyrosine kinase, which promotes activation of the distal signaling pathways and induces cellular effector responses (6, 21, 22). However, the functional role of the FcγR ITAM tyrosines has not been directly tested in neutrophils and neutrophil-dependent autoimmune diseases in vivo. Herein, we used a genetic approach to characterize the possible role of FcγR ITAM tyrosines in neutrophils and in vivo autoimmune arthritis. We demonstrated that FcγR ITAM tyrosines are required for the immune complex-dependent activation of neutrophils and the development and progression of experimental autoimmune arthritis.

MATERIALS AND METHODS

Animals

FcγRγ-deficient (Fec1g<sup>tm1Rav</sup>/tm1Rav<sup>+</sup>), referred to as FcγR KO) mice were purchased from Taconic Farms (Hudson, NY, USA) (10). Animals expressing the wild type and the ITAM tyrosine mutant FcγRγ (where tyrosines at positions 65 and 76 were replaced by phenylalanines) were described previously and were crossed with FcγR KO mice (referred to as FcγR KO + WT FcγR γ Tg and FcγR KO + YF FcγR γ Tg animals, respectively) (16). To augment the expression of the transgenic wild type and mutant FcγR γ chain, the mice were crossed to obtain homozygous, double transgenic animals (referred to as FcγR KO + 2x WT FcγR γ Tg and FcγR KO + 2x YF FcγR γ Tg mice, respectively). Single and double transgenic animals were differentiated by quantitative PCR. Mice carrying the KRN T-cell-receptor transgene were maintained in heterozygous form by mating with C57BL/6 mice (23). All transgenic mice were backcrossed to the C57BL/6 genetic background. Genotyping was performed by allele-specific PCR.

Wild type control C57BL/6 mice were purchased from Charles River or the Hungarian National Institute of Oncology (Budapest, Hungary). NOD mice, as well as a congenic strain carrying the CD45.1 allele on the C57BL/6 genetic background (B6.SJL-Ptpr<sup>cd</sup>) were purchased from the Jackson Laboratory.

Mice were kept in individually ventilated cages (Tecniplast) in a conventional facility. All animal experiments were approved by the Animal Experimentation Review Board of the Semmelweis University.

Abbreviations: FcγRγ, Fc receptor γ-chain; IC, Immune complex; ITAM, Immunoreceptor tyrosine-based activation motif; FcγR, Fc receptor; GPI, Glycosylphosphatidylinositol; PCR, Polymerase chain reaction; PMA, Phorbol myristate acetate; WT, Wild type.
Bone marrow chimeras were generated by intravenous injection of unfractionated bone marrow cells into recipients carrying the CD45.1 allele on the C57BL/6 genetic background, which were lethally irradiated before by 11 Gy from a 137Cs source using a Gamma-Service Medical (Leipzig, Germany) D1 irradiator. 4 weeks after transplantation, peripheral blood samples were stained for Ly6G and CD45.2 (Clones 1A8 and 104, respectively; both from BD Biosciences) and analyzed by a BD Biosciences FACSCalibur flow cytometer as previously described (21).

**K/B × N Serum-Transfer Arthritis**

Mice carrying the KRN T-cell receptor transgene on the C57BL/6 genetic background were mated with NOD mice to obtain transgene-positive (arithmetic) K/B ×N and transgene-negative (control) B × N mice (23, 24). The presence of the transgene was determined by allele-specific PCR and confirmed by phenotypic assessment. Blood was taken by retroorbital bleeding and sera from arthritic and control mice were pooled separately.

Arthritis was induced by a single intraperitoneal injection of 400 µl K/B × N (arthritic) or B × N (control) serum into intact mice or bone marrow chimeras, followed by daily assessment of arthritis severity for 2 weeks as described (24–26). Visible clinical signs were scored on a 0–10 scale by two investigators blinded for the origin and treatment of the mice. Ankle thickness was measured by a spring-loaded caliper (Kroeplin). For histological analysis, mice were sacrificed on Day 8, their fore limbs were removed, and femurs and tibias of intact mice or chimeras by hypotonic lysis followed by centrifugation using sterile and endotoxin-free reagents as described (25–27). Cell surface FcγRIV expression was detected by an anti-FcγRIV antibody (Clone 9E9; a gift from Prof. Jeffrey V. Ravetch). A secondary staining with FITC labeled anti-Armenian and Syrian hamster antibodies (Clones G70-204 and G94-56; BD Biosciences) was performed.

**Isolation and Activation of Neutrophils**

Mouse neutrophils were isolated from the bone marrow of the femurs and tibias of intact mice or chimeras by hypotonic lysis followed by Percoll (GE Healthcare) gradient centrifugation using sterile and endotoxin-free reagents as described (25–27). Cell surface FcγRIV expression was detected by an anti-FcγRIV antibody (Clone 9E9; a gift from Prof. Jeffrey V. Ravetch). A secondary staining with FITC labeled anti-Armenian and Syrian hamster antibodies (Clones G70-204 and G94-56; BD Biosciences) was performed.

Neutrophils were kept at room temperature in Ca2+- and Mg2+-free medium until use and prewarmed to 37°C prior to activation. Neutrophil assays were performed at 37°C in HBSS supplemented with 20 mM HEPES, pH 7.4. To obtain immobilized immune complex-coated surfaces, human lactoferrin (LFR; Sigma-Aldrich) was either bound directly to regular Nunc MaxiSorp F96 (Thermo Fisher) plates (for superoxide release and degranulation measurements) or covalently linked to poly-L-lysine-coated 24-well tissue culture plates (for spreading assays) and then treated with rabbit anti-LFR IgG (Sigma-Aldrich) as described (6). Superoxide release by neutrophils was followed by a cytochrome c reduction test from 100 µl aliquots of 4 × 106/ml cells plated on immobilized immune complexes or on 10% fetal cow serum (FCS) in the presence of PMA as described (25). The release of gelatinase was determined by gelatinase zymography as previously described (6). Spreading of the cells was followed by phase contrast microscopy.

**Biochemical Studies**

For analysis of protein contents, neutrophils were lysed in 100 mM NaCl, 30 mM Na-HEPES (pH 7.4), 20 mM NaF, 1 mM Na-EGTA, 1% Triton X-100, 1 mM benzamidine, freshly supplemented with 0.1 U/ml Aprotinin, 1:100 Mammalian Protease Inhibitor Cocktail, 1:100 Phosphatase Inhibitor Cocktail 2, 1 mM PMSF and 1 mM Na3VO4 (all from Sigma-Aldrich). After removal of insoluble material, lysates were boiled in sample buffer. Whole cell lysates were run on SDS-PAGE and immunoblotted using antibodies against FcαR (Host: rabbit; Upstate) or β-actin (Clone AC-74; Sigma-Aldrich) and peroxidase-labeled secondary antibodies (GE Healthcare). The signal was developed using the ECL system (GE Healthcare) and exposed to X-ray films.

**Presentation of the Data and Statistical Analysis**

Experiments were performed the indicated number of times. Quantitative graphs and kinetic curves show mean and SEM from all independent in vitro experiments or from all individual mice from the indicated number of experiments. Statistical analyses were carried out by the STATISTICA software using two-way (factorial) ANOVA, with treatment and genotype being the two independent variables. In case of kinetic assays, area under the curve (AUC) was used for statistical analysis. P values below 0.05 were considered statistically significant.

**RESULTS**

**FcRγ-Deficient Neutrophils Have Impaired Immune Complex-Mediated Cell Responses and Lack Activating Fc Receptors From the Cell Surface**

First, we characterized the phenotype of the FcRγ-deficient neutrophils. When plating on immobilized immune complex surfaces, freshly isolated wild type mouse neutrophils were able to produce superoxide, while in the absence of the FcγRIV the cell response was abolished (Figure 1A; P = 1.3 × 10−4). In line with this finding, FcγR-deficient neutrophils were unable to release the granule marker gelatinase or perform cell spreading (Figures 1B,C; P = 2.6 × 10−4 and P = 1.4 × 10−4). Meanwhile, the absence of the adaptor chain did not affect Fc receptor-independent superoxide production triggered by PMA compared to wild type cells (Figure 1D; P = 0.81). However, the activating, FcγR-associated FcγR receptor IV was found to be absent from the cell surface of FcRγ-deficient neutrophils (Figure 1E; P = 4.4 × 10−5).

**Restoration of FcRγ-Expression in Neutrophils by Wild Type and ITAM Mutant FcRγ**

For investigating the role of the intracellular ITAM tyrosines in various cell responses, we re-expressed wild type or ITAM
tyrosine mutant FcRγ in mice on an FcRγ-deficient background. According to the immunoblot results, neutrophils from the wild type and the ITAM tyrosine mutant FcRγ transgenic mice could produce the protein (Figure 2A; the expression level was 24% and 68% of the original wild type level, respectively; \( P = 2.2 \times 10^{-3} \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO). As a consequence, the activating Fcγ receptor IV appeared on the cell surface of the two different transgenic neutrophil populations (Figure 2B; the expression level was 25 and 43% of the maximum, respectively; \( P = 0.026 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO). We further analyzed the neutrophil counts in the periphery or in the bone marrow in wild type, FcRγ-deficient, wild type and ITAM mutant FcRγ-expressing mice and we did not detect significant differences in the sizes of the granulocyte populations (Figures 2C,D; \( P = 0.09 \) and \( P = 0.97 \), respectively). This indicated that transgenic re-expression of wild type and ITAM
tyrosine mutant FcRγ did not interfere with neutrophil survival and viability.

**FcRγ ITAM Tyrosines Are Critical for Immune Complex-Mediated Neutrophil Cell Responses**

Compared to FcRγ-deficient neutrophils, re-expression of the wild type FcRγ could partially restore the Fc receptor-mediated release of superoxide, while this response was totally blocked in connection with ITAM tyrosine mutant FcRγ-bearing cells (Figure 3A; \( P = 0.017 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO + YF FcRγ Tg and \( P = 0.75 \) for FcRγ KO + YF FcRγ Tg vs. FcRγ KO). The same essential role of these tyrosines could be observed in connection with gelatinase degranulation and cell spreading (Figures 3B,C; \( P = 0.04 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO + YF FcRγ Tg and \( P = 0.02 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO + YF FcRγ Tg, respectively). In contrast to immune complex-triggered conditions, PMA induced a robust superoxide production in all genotypes (Figure 3D; \( P = 0.90 \)).

**Essential Role of FcRγ ITAM Tyrosines in Arthritis Development**

For the *in vivo* studies, besides using intact mice, we also generated bone marrow, radiation chimeras in order to investigate the role of the FcRγ ITAM tyrosines in the myeloid compartment. In general, we did not see substantial differences between the arthritic phenotypes of the intact animals and the bone marrow chimeras. When receiving K/BxN serum, a small, but significant visible inflammation appeared on the fore and hind limbs of the wild type FcRγ transgenic mice that was totally missing from the animals with the ITAM mutant FcRγ (Figures 4A,B; \( P = 0.034 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO + YF FcRγ Tg and \( P = 0.61 \) for FcRγ KO + YF FcRγ Tg vs. FcRγ KO in connection with the fore limbs; \( P = 0.012 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO + YF FcRγ Tg and \( P = 0.87 \) for FcRγ KO + YF FcRγ Tg vs. FcRγ KO in connection with the hind limbs). However, we could not detect ankle thickness changes in the wild type FcRγ transgenic mice despite of a massive leukocyte infiltration to the joints seen on the histological sections in contrast to ITAM tyrosine mutant FcRγ expressing animals (Figures 4C,D; \( P = 0.27 \) for FcRγ KO + WT FcRγ Tg vs. FcRγ KO in Panel C).

**Augmentation of the Expression of the Transgenic Wild Type but not the ITAM Mutant FcRγ Enhances Arthritis Severity**

For raising the expression level of the wild type and ITAM mutant transgenic FcRγ, we crossed the single transgenic (hemizygous) mice to obtain double transgenic (homozygous) animals. As shown in Figure 5A, this process resulted in an obvious enhancement in the levels of FcRγ in neutrophils of the
FIGURE 3 | Critical role of the intracellular FcRγ ITAM tyrosines in mediating neutrophil cell responses in vitro. Wild type (WT), FcRγ-deficient (FcRγ KO), wild type FcRγ transgenic (FcRγ KO + WT FcRγ Tg) or ITAM tyrosine mutant FcRγ transgenic (FcRγ KO + YF FcRγ Tg) neutrophils were plated on immobilized immune complex surfaces and their superoxide release (A), gelatinase release (B) and cell spreading (C) was detected. The functionality of all genotypes was tested by PMA stimulation (D). Kinetic curves in (A,D) represent mean and SEM from 3 independent experiments. The gelatinase zymogram and the photos are representative of 3 independent experiments. See the text for actual P values. IC, Immune complex; PMA, Phorbol myristate acetate.
Re-expression of the wild type but not the ITAM tyrosine mutant FcRγ transgene partially reverses the arthritic phenotype. Wild type (WT), FcRγ-deficient (FcRγ KO), wild type FcRγ transgenic (FcRγ KO + WT FcRγ Tg) or ITAM tyrosine mutant FcRγ transgenic (FcRγ KO + YF FcRγ Tg) animals were injected with B×N (Control) or K/B×N (Arthritic) serum intraperitoneally on Day 0. Arthritis development was followed by clinical scoring of the fore limbs (A) and the hind limbs (B) and ankle thickness measurement (C). Leukocyte infiltration was visualized by microscopy after hematoxylin and eosin staining ([D], 20x original magnification, bars: 100 µm; asterisks point at infiltrating leukocytes). Quantitative data show mean and SEM from 6 to 7 control and 6 to 7 arthritic serum-treated individual mice per group from 3 independent experiments (A–C). See the text for actual P values.

homzygous transgenic mice compared to that of the hemizygous ones. The augmentation also appeared in the changes of the cell surface Fcγ receptor IV-expression (Figure 5B). Double transgenic wild type FcRγ bone marrow chimeras showed a robust arthritic phenotype on all limbs, while the double transgenic ITAM tyrosine mutant FcRγ chimeras were totally protected from arthritis development (Figures 5C,D; P = 0.04 for FcRγ KO + 2x WT FcRγ Tg vs. FcRγ KO + 2x YF FcRγ Tg and P = 0.70 for FcRγ KO + 2x YF FcRγ Tg vs. FcRγ KO in connection with the fore limbs; P = 9.2 × 10⁻³
FIGURE 5 | Dose-dependent effect of the wild type transgene on the severity of autoimmune arthritis in contrast to complete protection of the ITAM tyrosine mutant animals. FcRγ expression was tested by immunoblotting on whole cell lysates of neutrophils (A), while cell surface expression of the FcγRIV was followed by flow cytometry (B). (C–E) Wild type (WT), FcRγ-deficient (FcRγ KO), double wild type FcRγ transgenic (FcRγ KO + 2x WT FcRγ Tg) or double ITAM tyrosine mutant FcRγ transgenic (FcRγ KO + 2x YF FcRγ Tg) bone marrow chimeras were injected with B×N (Control) or K×B×N (Arthritic) serum intraperitoneally on Day 0. Arthritis development was followed by clinical scoring of the fore limbs (C) and the hind limbs (D) and ankle thickness measurement (E). The blot and the flow cytometric curves are representative of 4 independent experiments. Quantitative data show mean and SEM from 4 to 5 control and 5 to 6 arthritic serum-treated individual mice per group from 2 independent experiments (C–E). See the text for actual P values.

for FcRγ KO + 2x WT FcRγ Tg vs. FcRγ KO + 2x YF FcRγ Tg and P = 0.96 for FcRγ KO + 2x YF FcRγ Tg vs. FcRγ KO in connection with the hind limbs). Double wild type FcRγ transgenic bone marrow chimeras also showed a significant ankle thickening compared to the homozygous ITAM mutant FcRγ transgenic bone marrow chimeras (Figure 5E; P = 0.01 for FcRγ KO + 2x WT FcRγ Tg vs. FcRγ KO + 2x YF FcRγ Tg and P = 0.96 for FcRγ KO + 2x YF FcRγ Tg vs. FcRγ KO).

Our results indicate an essential role for the FcRγ ITAM tyrosines in immune complex-triggered neutrophil cell responses and experimental arthritis.

DISCUSSION

Our results show that FcRγ is critical to stabilize the expression of the activating Fcγ receptors in the plasma membrane and reveals that this function is independent from the presence of its ITAM tyrosines (Figure 2). Former in vitro studies demonstrated the importance of a non-covalent, salt bridge-mediated interaction between the Fcγ receptor and the ITAM-containing side chain in the endoplasmic reticulum to prevent the degradation of the complex and enable the transfer of the complex to the Golgi apparatus (28). It is thought that this process is involved in the regulation of the cell surface expression of Fcγ receptors.
Although our findings fit into this picture, further studies will be needed to characterize the intracellular mechanisms which stabilize and prevent the complex from degradation.

As a key observation, our structure-function studies revealed the importance of FcγR ITAM tyrosines in immune complex-mediated neutrophil effector functions including the release of reactive oxygen species, degranulation and spreading. These findings are in accordance with previous studies of basophilic cell lines, in which the role of ITAM tyrosines was shown in FcγRIIIA signaling, and in mast cells, where cell functions were abrogated after IgE-dependent stimulation (14, 16).

In vivo studies using murine wild type and ITAM tyrosine mutant transgenes suggested that the ITAM tyrosines are involved in degranulation, cytokine production, prostaglandin synthesis, and passive systemic anaphylaxis in mast cells (16). Even though the early in vivo studies on the NOTAM mouse carrying ITAM mutant FcγR indicated the ITAM-dependence of in vivo cytotoxicity, uptake of immune complexes, and the cross presentation of antigens in dendritic cells (17, 18), recent papers revealed that datarumumab-induced cancer cell death (after blocking FcγRIIB) and the splenic dendritic cell-mediated activation of CD4- and CD8-positive T cells occur in an FcγR ITAM-independent manner (19, 20). In connection to this, our in vivo studies indicate that FcγR ITAM signaling is essential for mediating the initiation and progression of autoimmune arthritis. However, further studies are needed to test whether—similarly to dendritic cells—ITAM independent signaling mechanisms are also involved in other in vivo functions of neutrophils. It would also be informative to test the role of the ITAM tyrosines of FcγR in other autoantibody-mediated disease models in the future to further support our findings with experimental arthritis.

In vitro and in vivo studies monitoring the phosphorylation state of ITAM tyrosines indicated that both ITAM tyrosines are phosphorylated upon stimulation, but the carboxy-terminal tends to be dephosphorylated much faster in mast cells (15). However, it is not known how the phosphorylation state of the two tyrosines is regulated in neutrophils.

It should be noted that not only FcγRIII and FcγRIV—the receptor that is alone sufficient to induce arthritis (7)—, but other receptors also are associated with FcγR, including Paired Immunglobulin-like receptor-A (PIR-A), Leukocyte immunglobulin-like receptor 1C (LILR1C), Osteoclast-associated receptor (OSCAR), T cell-interacting, activating receptor on myeloid cells-1 (TARM1), Dectin-2 or some β integrins in neutrophils (29–36). Further studies are needed whether the ligand binding or crosslinking of these receptors require the function of the FcγR ITAM tyrosines to enable the expression and induction of cellular responses.

As shown in Figures 2 and 5, the expression levels of the wild type and the FcγR ITAM mutant transgenic neutrophils are different. The presence of the complex between the ITAM-containing molecule and the Fcγ receptor has been reported in the endoplasmic reticulum, which is likely the cellular organism where the stability of the complex and the degradation of the components is actively regulated that may require the presence of the ITAM tyrosines (28). It is also possible that the copy numbers of the two transgenes are different. A third possibility is that different enhancer and silencer elements are involved in the regulation of the expression of the two transgenes as they may not be present at the same place in the genome. Most importantly, despite of the higher level, ITAM mutant FcγR was not able to restore neutrophil effector responses and reverse the development of autoimmune arthritis, which further support our conclusions.

Compared to the hemizygous animals, the double transgenic wild type FcγR mice could reverse more effectively the development of autoimmune arthritis in the FcγR-deficient background, indicating that the disease progression is highly dependent on the level of the signaling molecule. This can be the explanation of why the ankle thickness was not significantly changed, while the increase in the more sensitive clinical score was significant and the immune cell infiltration was massive and robust in the single wild type FcγR ITAM transgenic animals.

As the absence of FcγR was not required for neutrophil migration in experimental arthritis, it can be hypothesized that FcγR ITAM tyrosines are also not involved in the accumulation of neutrophils at the site of inflammation (37). These tyrosines could rather have a role in mediating immune complex-triggered responses at the site of tissue damage as we showed it in connection with several other molecules involved in neutrophil Fcγ receptor signaling (21, 24, 26).

Besides neutrophils, other cell types like macrophages, mast cells or platelets have been indicated in the pathogenesis of experimental arthritis (38–41). It would be interesting to test the role of the ITAM tyrosines of FcγR in these cell populations in joint inflammation. Collectively, our studies revealed the critical role of FcγR ITAM tyrosines in immune complex-mediated activation of neutrophils and the development and progression of autoantibody-induced autoimmune arthritis. Importantly, our studies provide the first direct in vivo evidence for the role of FcγR ITAM tyrosines in a neutrophil-dependent in vivo arthritis model. Understanding these molecular mechanisms can serve as new therapeutic targets in the treatment of some autoimmune diseases in the future (e.g., by the development of molecules which may mask the ITAM tyrosines of FcγR).

**AUTHOR CONTRIBUTIONS**

TN, AM, and ZJ designed the work, interpreted the results and wrote the paper. TN, KF, MS, PA, and ZJ performed the experiments and analyzed the data. TS developed and provided the wild type and ITAM mutant FcγR transgenic mouse strains.

**FUNDING**
