Abstract
This paper concerns the central issues of model robustness and sample efficiency in offline reinforcement learning (RL), which aims to learn to perform decision making from history data without active exploration. Due to uncertainties and variabilities of the environment, it is critical to learn a robust policy—with as few samples as possible—that performs well even when the deployed environment deviates from the nominal one used to collect the history dataset. We consider a distributionally robust formulation of offline RL, focusing on tabular robust Markov decision processes with an uncertainty set specified by the Kullback-Leibler divergence in both finite-horizon and infinite-horizon settings. To combat with sample scarcity, a model-based algorithm that combines distributionally robust value iteration with the principle of pessimism in the face of uncertainty is proposed, by penalizing the robust value estimates with a carefully designed data-driven penalty term. Under a mild and tailored assumption of the history dataset that measures distribution shift without requiring full coverage of the state-action space, we establish the finite-sample complexity of the proposed algorithm, and further show it is almost unimprovable in light of a nearly-matching information-theoretic lower bound up to a polynomial factor of the (effective) horizon length. To the best our knowledge, this provides the first provably near-optimal robust offline RL algorithm that learns under model uncertainty and partial coverage.

1 Introduction

Reinforcement learning (RL) concerns about finding an optimal policy that maximizes an agent’s expected total reward in an unknown environment. A fundamental challenge of deploying RL to real-world applications is the limited ability to explore or interact with the environment, due to resources, time, or safety constraints. Offline RL, or batch RL, seeks to circumvent this challenge by resorting to history data—which are often collected by executing some possibly unknown behavior policy in the past—with the hope that the history data might already provide significant insights about the targeted optimal policy without further exploration (Levine et al., 2020).

Besides maximizing the expected total reward, perhaps an equally important goal—to say the least—for an RL agent is safety and robustness (Garcia and Fernández, 2015), especially in high-stake applications such as robotics, autonomous driving, clinical trials, financial investments, and so on (Choi et al., 2009; Schulman et al., 2013). It has been observed that a standard RL agent trained in an ideal environment might be extremely sensitive and fail catastrophically when the deployed environment is subject to small adversarial perturbations (Zhang et al., 2020). Consequently, robust RL has attracted a surge of attentions with the goal to learn an optimal policy that is robust to environment perturbations. In fact, providing robustness guarantees becomes even more relevant in the offline setting, which can be formulated as robust offline RL, since the history data is often inevitably collected from a timeframe where it is no longer reasonable to assume model stillness, due to the highly non-stationary and time-varying dynamics of many real-world applications. Altogether, this naturally leads to a question: Can we learn a near-optimal policy which is robust with respect to uncertainties and variabilities of the environments using as few history samples as possible?

1.1 Challenges and premises in robust offline RL

Despite significant amount of recent activities in robust RL and offline RL, addressing model uncertainty and sample efficiency simultaneously remains challenging due to several key issues that we single out below.
• Distribution shift. The history data is generated by following some behavior policy in an outdated environment, which can result in a data distribution that is heavily deviated from the desired one, i.e., induced by the target policy in the deployed environment.

• Partial and limited coverage. The history data might only provide partial and limited coverage over the entire state-action space, where the limited sample size leads to a poor estimate of the associated model parameters, and consequently, unreliable policy learning outcomes.

Understanding the implications of—and designing algorithms that work around—these challenges play a major role in advancing the state-of-the-art of robust offline RL. In particular, two prevalent algorithmic ideas, distributional robustness and pessimism, are called out as our guiding principles.

• Distributional robustness. Instead of finding an optimal policy in a fixed environment, motivated by the literature in distributionally robust optimization (Delage and Ye, 2010), one might seek to find a policy that achieves the best worst-case performance for all the environments in some uncertainty set around the offline environment, as formulated in the framework of robust RL (Iyengar, 2005; Nilim and El Ghaoui, 2005).

• Pessimism. When the samples are scarce, it is wise to act with caution based on the principle of pessimism, where one subtracts a penalty term—representing the confidence of the corresponding estimate—from the value functions to avoid excessive risk. Encouragingly, pessimism has been recently shown as an indispensable ingredient to achieve sample efficiency in offline RL without requiring full coverage (Jin et al., 2021; Li et al., 2022; Rashidinejad et al., 2021), as long as the trajectory of the behavior policy provides sufficient overlap with that of the target policy.

While these two ideas have been proven useful for robust RL and offline RL separately, tackling robust offline RL needs novel ingredients that go significantly beyond a naïve combination of existing techniques. This is because, in robust offline RL, one needs to handle the distribution shift induced not only by the behavior policy, but also by model perturbations, thus the penalty term derived from the pessimism principle in standard offline RL is no longer applicable. In short, while the value function of standard RL depends linearly with respect to the transition kernel, the dependency between the nominal transition kernel and the robust value function unfortunately becomes highly nonlinear—even without a closed-form expression—making the control of statistical uncertainty extremely challenging in robust offline RL.

1.2 Main contributions

In this work, we provide an affirmative answer to the question raised earlier, by developing a provably efficient model-based algorithm that learns a near-optimal distributionally-robust policy from a minimal number of offline samples. Specifically, we consider a Robust Markov Decision Process (RMDP) with $S$ states, $A$ actions in both the nonstationary finite-horizon setting (with horizon length $H$) and the discounted infinite-horizon setting (with discount factor $\gamma$). Different from standard MDPs, RMDPs specify a family transition kernels, which lie within an uncertainty set taken as a small ball of size $\sigma$ around a nominal transition kernel with respect to the Kullback-Leibler (KL) divergence. Given $K$ episodes (resp. $N$ transitions) of history data drawn by following some behavior policy $\pi^b$ under the nominal transition kernel in the finite-horizon (resp. infinite-horizon) setting, our goal is to learn the optimal robust policy $\pi^*$ in the maximin sense, which has the best worst-case value for all the models within the uncertainty set (Iyengar, 2005; Nilim and El Ghaoui, 2005). Our main results are summarized below.

• We introduce a notion called robust single-policy clipped concentrability coefficient $C^r_{\text{rob}} \in [1/S, \infty]$ to quantify the quality of history data, which measures the distribution shift between the behavior policy $\pi^b$ and the optimal robust policy $\pi^*$ in the presence of model perturbations, without requiring full coverage of the entire state-action space by the behavior policy. In contrast, prior algorithms (Panaganti and Kalathil, 2022; Yang et al., 2021; Zhou et al., 2021)—using simulator or offline data—all require full coverage of the entire state-action space.

• We propose a novel pessimistic variant of distributionally robust value iteration with a plug-in estimate of the nominal transition kernel (Iyengar, 2005; Nilim and El Ghaoui, 2005), called DRVI-LCB, by
Table 1: Our results for finding an \(\varepsilon\)-optimal robust policy in the infinite/finite-horizon robust MDPs with an uncertainty set measured with respect to the KL divergence using history data under partial coverage. The sample complexities included in the table are valid for sufficiently small \(\varepsilon\), with all logarithmic factors omitted. Here, \(\sigma\) is the uncertainty level, \(C^{\star}_{\text{rob}}\) is the robust single-policy clipped concentrability coefficient, \(P^{\star}_{\min}\) is the smallest positive state transition probability of the nominal kernel visited by the optimal robust policy \(\pi^{\star}\).

| Horizon   | Algorithm               | Coverage | Sample complexity          |
|-----------|-------------------------|----------|---------------------------|
| infinite  | DRVI-LCB (this work)    | partial  | \(\frac{SC^{\star}_{min}}{P^{\star}_{\min}(1-\gamma)^{2}\sigma^{2}\varepsilon^{2}}\) |
|           | Lower bound (this work) | partial  | \(\frac{SC^{\star}_{min}}{P^{\star}_{\min}(1-\gamma)^{2}\sigma^{2}\varepsilon^{2}}\) |
| finite    | DRVI-LCB (this work)    | partial  | \(\frac{SC^{\star}_{min}}{P^{\star}_{\min}\sigma^{2}\varepsilon^{2}}\) |
|           | Lower bound (this work) | partial  | \(\frac{SC^{\star}_{min}}{P^{\star}_{\min}\sigma^{2}(1-\gamma)^{2}\varepsilon^{2}}\) |

penalizing the robust value estimates with a carefully designed data-driven penalty term. We demonstrate that DRVI-LCB finds an \(\varepsilon\)-optimal robust policy as soon as the sample size is above \(\tilde{O}\left(\frac{SC^{\star}_{min}H^{3}}{P^{\star}_{\min}\sigma^{2}(1-\gamma)^{2}\varepsilon^{2}}\right)\) for the finite-horizon setting and \(\tilde{O}\left(\frac{SC^{\star}_{min}}{P^{\star}_{\min}\sigma^{2}(1-\gamma)^{2}\varepsilon^{2}}\right)\) for the infinite-horizon setting, up to some logarithmic factor after a burn-in cost independent of \(\varepsilon\). Here, \(P^{\star}_{\min}\) is the smallest positive state transition probability of the optimal robust policy \(\pi^{\star}\) under the nominal kernel.

- To complement the upper bound, we further develop an information-theoretic lower bound, where there exists some robust MDP such that at least \(\Omega\left(\frac{SC^{\star}_{min}H^{3}}{P^{\star}_{\min}\sigma^{2}(1-\gamma)^{2}\varepsilon^{2}}\right)\) samples (resp. \(\Omega\left(\frac{SC^{\star}_{min}}{P^{\star}_{\min}\sigma^{2}(1-\gamma)^{2}\varepsilon^{2}}\right)\) samples) are needed to find an \(\varepsilon\)-optimal robust policy regardless of the choice of algorithms in the finite-horizon (resp. infinite-horizon) setting. Hence, this corroborates the near-optimality of DRVI-LCB with respect to all key parameters up to a polynomial factor of the horizon length \(H\) (resp. the effective horizon length \(\frac{1}{1-\gamma}\)).

To the best of our knowledge, our paper is the first work to execute the principle of pessimism in a data-driven manner for robust offline RL, leading to the first provably near-optimal algorithm that learns under simultaneous model uncertainty and partial coverage of the history dataset. See Table 1 for a summary.

**Comparison with prior art under full coverage.** In truth, prior works (Panaganti and Kalathil, 2022; Yang et al., 2021; Zhou et al., 2021) have only addressed the infinite-horizon setting under full coverage of the history data. Specializing our result to this setting, DRVI-LCB finds an \(\varepsilon\)-optimal robust policy with at most \(\tilde{O}\left(\frac{SA}{P^{\star}_{\min}(1-\gamma)^{2}\sigma^{2}\varepsilon^{2}}\right)\) samples, which depends linearly with respect to the size of the state space \(S\) (ignoring other parameters). In contrast, all prior works (Panaganti and Kalathil, 2022; Yang et al., 2021; Zhou et al., 2021) incur sample complexities that scale at least quadratically with respect to the size of the state space \(S\). In addition, our bound improves the exponential dependency on \(\frac{1}{P^{\star}_{\min}}\) of Panaganti and Kalathil (2022); Zhou et al. (2021) to a polynomial dependency, as well as the quadratic dependency on \(1/P^{\star}_{\min}\) (which satisfies \(P^{\star}_{\min} \leq P^{\star}_{\min}\)) of Yang et al. (2021) to a linear one on \(1/P^{\star}_{\min}\). These improvements further corroborate the benefit of the proposed DRVI-LCB even under full coverage. See Table 2 for detailed comparisons.

### 1.3 Related works

We shall focus on the closely related works on offline RL and distributionally robust RL.
| Problem type | Algorithm                        | Coverage | Sample complexity                                                                 |
|--------------|----------------------------------|----------|-----------------------------------------------------------------------------------|
| infinite     | DRVI (Zhou et al., 2021)         | full     | $\frac{S^2 A \exp(O(\frac{1}{\epsilon^2}))}{(1-\gamma)^5 \sigma^2 \epsilon^2}$ |
|              | REVI/DRVI (Panaganti and Kalathil, 2022) | full     | $\frac{S^2 A \exp(O(\frac{1}{\epsilon^2}))}{(1-\gamma)^5 \sigma^2 \epsilon^2}$ |
|              | DRVI (Yang et al., 2021)         | full     | $\frac{S^2 A}{P_{\min}^2 (1-\gamma)^5 \sigma^2 \epsilon^2}$                   |
|              | DRVI-LCB (this work)             | full     | $\frac{SA}{P_{\min}^4 (1-\gamma)^5 \sigma^2 \epsilon^2}$                     |

Table 2: Comparisons between our results and prior arts for finding an $\epsilon$-optimal robust policy in the infinite/finite-horizon robust MDPs with an uncertainty set measured with respect to the KL divergence under full coverage of the history data. The sample complexities included in the table are valid for sufficiently small $\epsilon$, with all logarithmic factors omitted. Here, $\sigma$ is the uncertainty level, $P_{\min}^*$ is the smallest positive state transition probability of the nominal kernel visited by the optimal robust policy $\pi^*$, and $P_{\min}$ is the smallest positive state transition probability of the nominal kernel; it holds $P_{\min} \leq P_{\min}^*$.

Offline RL. Focusing on the task of learning an optimal policy from offline data, a significant amount of prior arts sets to understand the sample complexity and efficacy of offline RL under different assumptions of the history dataset. A bulk of prior results requires the history data to cover all the state-action pairs, under assumptions such as uniformly bounded concentrability coefficients (Chen and Jiang, 2019; Munos, 2005) and uniformly lower bounded data visitation distribution (Yin et al., 2021; Yin and Wang, 2021), where the latter assumption is also related to studies of asynchronous Q-learning (Li et al., 2021). More recently, the principle of pessimism has been investigated for offline RL in both model-based (Jin et al., 2021; Li et al., 2022; Rashidinejad et al., 2021; Xie et al., 2021) and model-free algorithms (Kumar et al., 2020; Shi et al., 2022; Yan et al., 2022), without the stringent requirement of full coverage. In particular, Li et al. (2022) established the near-minimax optimality of a pessimistic variant of value iteration under the single-policy clipped concentrability of history data, which inspired our algorithm design in the distributionally robust setting.

Distributionally robust RL. While distributionally robust optimization has been mainly investigated in the context of supervised learning (Bertsimas et al., 2018; Blanchet and Murthy, 2019; Duchi and Namkoong, 2018; Gao, 2020; Rahimian and Melo, 2019), distributionally robust dynamic programming has also attracted considerable amount of attention, e.g. Iyengar (2005); Nilim and El Ghaoui (2005); Nilim and Ghaoui (2003); Xu and Mannor (2012), where natural robust extensions to the standard Bellman machineries are developed under mild assumptions. Targeting robust MDPs, empirical and theoretical works have been widely explored under different forms of uncertainty sets (Badrinath and Kalathil, 2021; Derman and Mannor, 2020; Goyal and Grand-Clement, 2022; Ho et al., 2018, 2021; Iyengar, 2005; Kaufman and Schaefer, 2013; Smirnova et al., 2019; Tamar et al., 2014; Wolff et al., 2012; Xu and Mannor, 2012). Nonetheless, the majority of prior theoretical analyses focus on planning with an exact knowledge of the uncertainty set (Iyengar, 2005; Tamar et al., 2014; Xu and Mannor, 2012), or are asymptotic in nature (Roy et al., 2017).

A number of robust RL algorithms were proposed recently with an emphasis on finite-sample performance guarantees under different data generating mechanisms. Wang and Zou (2021) proposed a robust Q-learning algorithm with an R-contamination uncertain set for the online setting, which achieves a similar bound as its non-robust counterpart. Badrinath and Kalathil (2021) proposed a model-free algorithm for the online setting with linear function approximation to cope with large state spaces. Panaganti and Kalathil (2022); Yang et al. (2021) developed sample complexities for a model-based robust RL algorithm with a variety of uncertainty sets where the data are collected using a generative model. In addition, Zhou et al. (2021) examined the uncertainty set defined by the KL divergence for offline data with uniformly lower bounded data visitation distribution. These works all require full coverage of the state-action space, whereas ours is the first one to leverage the principle of pessimism in robust offline RL.
1.4 Notation

Throughout this paper, we denote by $\Delta(S)$ the probability simplex over a set $S$, and introduce the notation $\{H\} := \{1, \cdots, H\}$ for any positive integer $H > 0$. In addition, for any vector $x = [x(s,a)]_{(s,a)\in S \times A} \in \mathbb{R}^{S \times A}$ (resp. $x = [x(s)]_{s \in S} \in \mathbb{R}^S$) that constitutes certain values for each state-action pair (resp. state), we overload the notation by letting $x^2 = [x(s,a)^2]_{(s,a)\in S \times A}$ (resp. $x^2 = [x(s)^2]_{s \in S}$). Moreover, for any two vectors $x = [x_i]_{1 \leq i \leq n}$ and $y = [y_i]_{1 \leq i \leq n}$, the notation $x \leq y$ (resp. $x \geq y$) means $x_i \leq y_i$ (resp. $x_i \geq y_i$) for all $1 \leq i \leq n$. Finally, the Kullback-Leibler (KL) divergence for any two distributions $P$ and $Q$ is denoted as $\text{KL}(P \parallel Q)$.

2 Problem formulation: episodic finite-horizon RMDPs

2.1 Basics of finite-horizon episodic tabular MDPs

Consider an episodic finite-horizon MDP, represented by $\mathcal{M} = (S, A, H, P := \{P_h\}_{h=1}^H, \{r_h\}_{h=1}^H)$, where $S = \{1, \cdots, S\}$ and $A = \{1, \cdots, A\}$ are the finite state and action spaces, respectively, $H$ is the horizon length, $P_h : S \times A \to \Delta(S)$ (resp. $r_h : S \times A \to [0, 1]$) denotes the probability transition kernel (resp. reward function) at the step $h$ ($1 \leq h \leq H$).\footnote{Without loss of generality, we assume the reward function is deterministic, fixed, and normalized to be within $[0, 1]$; it is straightforward to generalize our framework to incorporate random rewards with uncertainties.} For any transition kernel $P$, we introduce the $S$-dimensional distribution vectors

$$P_{h,s,a} := P_h(\cdot | s, a) \in [0, 1]^{\times S}, \quad \forall (h, s, a) \in [H] \times S \times A$$

(1)

to represent the probability transition vector in state $s$ when taking action $a$ at step $h$.

Denote $\pi = \{\pi_h\}_{h=1}^H$ as the policy or action selection rule of an agent, where $\pi_h : S \to \Delta(A)$ specifies the action selection probability over the action space; when the policy is deterministic, we slightly abuse the notation and refer to $\pi_h(s)$ as the action selected by policy $\pi$ in state $s$ at step $h$. The value function $V^{\pi,P} = \{V_h^{\pi,P}\}_{h=1}^H$ of policy $\pi$ with a transition kernel $P$ is defined by

$$\forall (h, s) \in [H] \times S : \quad V_h^{\pi,P}(s) := \mathbb{E}_{\pi,P}\left[\sum_{t=h}^{H} r_t(s_t,a_t) \mid s_h = s\right]$$

(2)

where the expectation is taken over the randomness of the trajectory $\{s_h,a_h,r_h\}_{h=1}^H$ generated by executing policy $\pi$, namely, $a_t \sim \pi_t(s_t)$, and $s_{t+1} \sim P_t(\cdot | s_t,a_t)$. Similarly, the Q-function $Q^{\pi,P} = \{Q_h^{\pi,P}\}_{h=1}^H$ of policy $\pi$ is defined as

$$\forall (h, s, a) \in [H] \times S \times A : \quad Q_h^{\pi,P}(s,a) := r_h(s,a) + \mathbb{E}_{\pi,P}\left[\sum_{t=h+1}^{H} r_t(s_t,a_t) \mid s_h = s, a_h = a\right]$$

(3)

where the expectation is again taken over the randomness of the trajectory.

Moreover, when the initial state $s_1$ is drawn from a given distribution $\rho$, let $d_h^{\pi,P}(s \mid \rho)$ and $d_h^{\pi,P}(s,a \mid \rho)$ denote respectively the state occupancy distribution and the state-action occupancy distribution induced by $\pi$ at time step $h \in [H]$, i.e.,

$$\forall (h, s) \in [H] \times S : \quad d_h^{\pi,P}(s) := \mathbb{P}(s_h = s \mid s_1 \sim \rho, \pi, P),$$

(4a)

$$\forall (h, s, a) \in [H] \times S \times A : \quad d_h^{\pi,P}(s,a) := \mathbb{P}(s_h = s \mid s_1 \sim \rho, \pi, P) \pi_h(a \mid s),$$

(4b)

which are conditioned on $s_1 \sim \rho$ and the event that all actions and states are drawn according to policy $\pi$ and transition kernel $P$. In particular, we often dropped the dependency with respect to $\rho$ whenever it is clear from the context, by simply writing $d_h^{\pi,P}(s) := d_h^{\pi,P}(s \mid \rho)$ and $d_h^{\pi,P}(s,a) := d_h^{\pi,P}(s,a \mid \rho)$.\footnote{Without loss of generality, we assume the reward function is deterministic, fixed, and normalized to be within $[0, 1]$; it is straightforward to generalize our framework to incorporate random rewards with uncertainties.}
2.2 Distributionally robust MDPs

In this work, we focus on finite-horizon episodic distributionally robust MDPs (RMDPs), denoted by $\mathcal{M}_{\text{rob}} = (\mathcal{S}, \mathcal{A}, H, \mathcal{U}^0(P^0), \{r_h\})_{h=1}^H$. Different from standard MDPs, we now consider an ensemble of probability transition kernels or models within an uncertainty set centered around a nominal one $P^0 = \{P^0_h\}_{h=1}^H$, where the distance between the transition kernels is measured in terms of the Kullback-Leibler (KL) divergence. Specifically, given an uncertainty level $\sigma > 0$, the uncertainty set around $P^0$, which satisfies the so-called rectangularity condition (Wiesemann et al., 2013), is specified as

$$ \mathcal{U}^\sigma(P^0) := \otimes \mathcal{U}^\sigma(P^0_{h,s,a}) := \{P_{h,s,a} \in \Delta(\mathcal{S}) : \text{KL}(P_{h,s,a} \parallel P^0_{h,s,a}) \leq \sigma\}, \quad (5) $$

where $\otimes$ denote the Cartesian product. In words, the KL divergence between the true transition probability vector and the nominal one at each state-action pair is at most $\sigma$; moreover, the RMDP reduces to the standard MDP when $\sigma = 0$.

Instead of evaluating a policy in a fixed MDP, the performance of a policy in the RMDP is evaluated based on its worst-case—i.e., smallest—value function over all the instances in the uncertainty set. That is, we define the robust value function $V^{\pi,\sigma} = \{V^{\pi,\sigma}_h\}_{h=1}^H$ and the robust Q-function $Q^{\pi,\sigma} = \{Q^{\pi,\sigma}_h\}_{h=1}^H$ respectively as

$$ \forall (h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A} : \quad V^{\pi,\sigma}_h(s) := \inf_{P \in \mathcal{U}^\sigma(P^0)} V^{\pi,P}_h(s), \quad Q^{\pi,\sigma}_h(s, a) := \inf_{P \in \mathcal{U}^\sigma(P^0)} Q^{\pi,P}_h(s, a), $$

where the infimum is taken over the uncertainty set of transition kernels.

**Optimal robust policy.** For finite-horizon RMDPs, it has been established that there exists at least one deterministic policy that maximizes the robust value function and Q-function simultaneously (Iyengar, 2005; Nilim and El Ghaoui, 2005). In view of this, we shall denote a deterministic policy $\pi^* = \{\pi^*_h\}_{h=1}^H$ as an optimal robust policy throughout this paper. The resulting optimal robust value function $V^{\pi^*,\sigma} = \{V^{\pi^*,\sigma}_h\}_{h=1}^H$ and optimal robust Q-function $Q^{\pi^*,\sigma} = \{Q^{\pi^*,\sigma}_h\}_{h=1}^H$ are denoted by

$$ \forall (h, s) \in [H] \times \mathcal{S} : \quad V^{\pi^*,\sigma}_h(s) := V^{\pi^*,\sigma}_h(s) = \max_{\pi} V^{\pi,\sigma}_h(s), $$

$$ \forall (h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A} : \quad Q^{\pi^*,\sigma}_h(s, a) := Q^{\pi^*,\sigma}_h(s, a) = \max_{\pi} Q^{\pi,\sigma}_h(s, a). \quad (6a,b) $$

Similar to (4), we adopt the following short-hand notation for the occupancy distributions associated with the optimal policy:

$$ \forall (h, s) \in [H] \times \mathcal{S} : \quad d^{\pi^*,\sigma}_h(s) := d^{\pi^*,\sigma}_h(s), $$

$$ \forall (h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A} : \quad d^{\pi^*,\sigma}_h(P, s, a) := d^{\pi^*,\sigma}_h(P, s, a) \mathbb{1}\{a = \pi^*_h(s)\}. \quad (7a,b) $$

**Robust Bellman equations.** It turns out the Bellman’s principle of optimality can be extended naturally to its robust counterpart (Iyengar, 2005; Nilim and El Ghaoui, 2005), which plays a fundamental role in solving the RMDP. To begin with, for any policy $\pi$, the robust value function and robust Q-function satisfy the following robust Bellman consistency equation:

$$ \forall (h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A} : \quad Q^{\pi,\sigma}_h(s, a) = r_h(s, a) + \inf_{P \in \mathcal{U}^\sigma(P^0_{h,s,a})} \mathbb{P} V^{\pi,\sigma}_{h+1}. \quad (8) $$

Additionally, the optimal robust Q-function obeys the robust Bellman optimality equation:

$$ \forall (h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A} : \quad Q^{\pi^*,\sigma}_h(s, a) = r_h(s, a) + \inf_{P \in \mathcal{U}^\sigma(P^0_{h,s,a})} \mathbb{P} V^{\pi^*,\sigma}_{h+1}, \quad (9) $$

which can be solved efficiently via a robust variant of value iteration when the RMDP is known (Iyengar, 2005; Nilim and El Ghaoui, 2005).
2.3 Distributionally robust offline RL

Let \( \mathcal{D} \) be a history/batch dataset, which consists of a collection of \( K \) independent episodes generated based on executing a behavior policy \( \pi^b = \{ \pi^b_h \}_{h=1}^K \) in some nominal MDP \( \mathcal{M}^0 = (S, A, H, P^0) := \{ P^0_h \}_{h=1}^K \). More specifically, for \( 1 \leq k \leq K \), the \( k \)-th episode \( (s^k_1, a^k_1, \ldots, s^k_H, a^k_H, s^k_{H+1}) \) is generated according to

\[
\begin{align*}
  s^k_1 & \sim \rho^b,  \\
  a^k_h & \sim \pi^b_h(\cdot | s^k_h) \quad \text{and} \quad s^k_{h+1} & \sim P^0_h(\cdot | s^k_h, a^k_h), \quad 1 \leq h \leq H. \tag{10}
\end{align*}
\]

Throughout the paper, \( \rho^b \) represents for some initial distribution associated with the history dataset. Then, we introduce the following short-hand notation for the occupancy distribution w.r.t. \( \pi^b \) in the nominal model:

\[
\forall (h, s, a) \in [H] \times S \times A : \quad d^b_h(s) := d^b_{h,P^0}(s), \quad d^b_{h}(s, a) := d^b_{h,P^0}(s, a). \tag{11}
\]

Robust single-policy clipped concentrability. To quantify the quality of the history dataset, it is desirable to capture the distribution mismatch between the history dataset and the desired ones, inspired by the \( \text{single-policy clipped concentrability} \) assumption recently proposed by Li et al. (2022), we introduce a tailored assumption for robust MDPs as follows.

**Assumption 1** (Robust single-policy clipped concentrability). The behavior policy of the history dataset \( \mathcal{D} \) satisfies

\[
\max_{(s,a,h,P) \in S \times A \times [H] \times \mathcal{U}^p(P^0)} \min \left\{ \frac{d^*_h(s, a, \frac{1}{S})}{d^b_h(s, a)} \right\} \leq C^*_{\text{rob}} \tag{12}
\]

for some quantity \( C^*_{\text{rob}} \in \left[ \frac{1}{S}, \infty \right] \). Here, we take \( C^*_{\text{rob}} \) to be the smallest quantity satisfying (12), and refer to it as the robust single-policy clipped concentrability coefficient. In addition, we follow the convention \( 0/0 = 0 \).

In words, \( C^*_{\text{rob}} \) measures the worst-case discrepancy—between the optimal robust policy \( \pi^* \) in any model \( P \in \mathcal{U}^p(P^0) \) within the uncertainty set and the behavior policy \( \pi^b \) in the nominal model \( P^0 \)—in terms of the maximum density ratio of the state-action occupancy distributions.

- **Distribution shift.** When the uncertainty level \( \sigma = 0 \), Assumption 1 reduces back to the single-policy clipped concentrability in Li et al. (2022) for standard offline RL, a weaker notion that can be \( S \) times smaller than the single-policy concentrability adopted in (Rashidinejad et al., 2021; Shi et al., 2022; Xie et al., 2021). On the other end, whenever \( \sigma > 0 \), the proposed robust single-policy clipped concentrability accounts for the distribution shift not only due to the policies in use (\( \pi^* \) versus \( \pi^b \)), but also the underlying environments (\( P \in \mathcal{U}^p(P^0) \) versus \( P^0 \)).

- **Partial coverage.** As long as \( C^*_{\text{rob}} \) is finite, i.e., \( C^*_{\text{rob}} < \infty \), it admits the scenarios when the history dataset only provides \textit{partial coverage} over the entire state-action space, as long as the behavior policy \( \pi^b \) visits the state-action pairs that are visited by the optimal robust policy \( \pi^* \) under at least one model in the uncertainty set.

**Remark 1.** To facilitate comparison with prior works assuming full coverage, we can bound \( C^*_{\text{rob}} \) when the batch dataset is generated using a simulator (Panaganti and Kalathil, 2022; Yang et al., 2021); namely, we can generate sample state transitions based on the transition kernel of the nominal MDP for all state-action pairs at all time steps. In this case, it amounts to that \( d^b_h(s, a) = \frac{1}{S^3} \) for all \( (s, a, h) \in S \times A \times [H] \), which directly leads to the bound \( C^*_{\text{rob}} = \max_{(s,a,h,P) \in S \times A \times [H] \times \mathcal{U}^p(P^0)} \min \left\{ \frac{d^*_h(s, a, \frac{1}{S})}{d^b_h(s, a)} \right\} \leq \frac{1}{S^3} \frac{1}{1/S^3} = A \).

**Goal.** With the history dataset \( \mathcal{D} \) in hand, our goal is to find a near-optimal robust policy \( \hat{\pi} \), which satisfies

\[
V^\hat{\pi}_{1,\sigma}(\rho) \geq V^{\pi^*_1,\sigma}(\rho) - \varepsilon \tag{13}
\]

using as few samples as possible, where \( \varepsilon \) is the target accuracy level, and

\[
V^{\pi^*_1,\sigma}(\rho) := \mathbb{E}_{s_1 \sim \rho} \left[ V^{{\pi^*_1,\sigma}}(s_1) \right] \quad \text{and} \quad V^{{\pi^*_1,\sigma}}(\rho) := \mathbb{E}_{s_1 \sim \rho} \left[ V^{{\pi^*_1,\sigma}}(s_1) \right] \tag{14}
\]

are evaluated when the initial state \( s_1 \) is drawn from a given distribution \( \rho \).
3 Algorithm and theory: episodic finite-horizon RMDPs

In this section, we present a model-based algorithm—namely DRVI-LCB—for robust offline RL, along with its performance guarantees.

3.1 Building an empirical nominal MDP

For a moment, imagine we have access to $N$ independent sample transitions $D_0 := \{(h_i, s_i, a_i, s'_i)\}_{i=1}^N$ drawn from the transition kernel $P^0$ of the nominal MDP $\mathcal{M}^0$, where each sample $(h_i, s_i, a_i, s'_i)$ indicates the transition from state $s_i$ to state $s'_i$ when action $a_i$ is taken at step $h_i$, drawn according to $s'_i \sim P^0_{h_i} (\cdot | s_i, a_i)$. It is then natural to build an empirical estimate $\hat{P}^0 = \{\hat{P}^0_h\}_{h=1}^H$ of $P^0$ based on the empirical frequencies of state transitions, where

$$\hat{P}^0_h (s' | s, a) := \begin{cases} \frac{1}{N_h(s,a)} \sum_{i=1}^N \mathbb{1} \{ (h_i, s_i, a_i, s'_i) = (h, s, a, s') \}, & \text{if } N_h(s,a) > 0 \\ 0, & \text{else} \end{cases}$$

(15)

for any $(h, s, a, s') \in [H] \times \mathcal{S} \times \mathcal{A} \times \mathcal{S}$. Here, $N_h(s,a)$ denotes the total number of sample transitions from $(s,a)$ at step $h$ as

$$N_h(s,a) := \sum_{i=1}^N \mathbb{1} \{ (h_i, s_i, a_i) = (h, s, a) \}.$$ 

(16)

While it is possible to directly break down the history dataset $\mathcal{D}$ into sample transitions, unfortunately, the sample transitions from the same episode are not independent, significantly hurling the analysis. To alleviate this, Li et al. (2022, Algorithm 2) proposed a simple two-fold subsampling scheme to preprocess the history dataset $\mathcal{D}$ and decouple the statistical dependency, resulting into a distributionally equivalent dataset $\mathcal{D}_0$ with independent samples. We have the following lemma paraphrased from Li et al. (2022).

**Lemma 1** (Li et al., 2022, Lemma 1 and Lemma 5). With probability at least $1-8\delta$, the output dataset from the two-fold subsampling scheme in Li et al. (2022) is distributionally equivalent to $\mathcal{D}_0$, where $\{N_h(s,a)\}$ are independent and obey

$$N_h(s,a) \geq \frac{K d_0^h(s,a)}{8} - 5 \sqrt{K d_0^h(s,a) \log \frac{KH}{\delta}}.$$ 

(17)

for all $(h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A}$.

By invoking the two-fold sampling trick from Li et al. (2022), it is sufficient to treat the dataset $\mathcal{D}_0$ with independent samples onwards with Lemma 1 in place.

3.2 DRVI-LCB: a pessimistic variant of robust value iteration

Armed with the estimate $\hat{P}^0$ of the nominal transition kernel $P^0$, we are positioned to introduce our algorithm DRVI-LCB, summarized in Algorithm 1.

**Distributionally robust value iteration.** Before proceeding, let us recall the update rule of the classical distributionally robust value iteration (DRVI), which serves as the basis of our algorithmic development. Given an estimate of the nominal MDP $\hat{P}^0$ and the radius $\sigma$ of the uncertainty set, DRVI updates the robust value functions according to

$$\hat{Q}_h(s,a) = r_h(s,a) + \inf_{p \in \mathcal{P}^0_{h,s,a}} \hat{P} \hat{V}_{h+1}, \quad \text{and} \quad \hat{V}_h(s) = \max_a \hat{Q}_h(s,a),$$

(18)

which works backwards from $h = H$ to $h = 1$, with the terminal condition $\hat{Q}_{H+1} = 0$. Due to strong duality (Hu and Hong, 2013), the update rule of the robust Q-functions in (18) can be equivalently reformulated in
Before stating the main theorems, let us first introduce several important metrics.

- \( P_{\text{min}}^* \), which only depends on the state-action pairs covered by the optimal robust policy \( \pi^* \) under the nominal model \( P^0 \):
  \[
  P_{\text{min}}^* := \min_{h,s,s'} \left\{ P^0_h(s'|s,\pi^*_h(s)) : P^0_h(s'|s,\pi^*_h(s)) > 0 \right\}.
  \]
In words, \( P^{\star}_{\min} \) is the smallest positive state transition probability of the optimal robust policy \( \pi^{\star} \) under the nominal kernel \( P^{0} \).

\[ \star \]

- Similarly, we introduce \( P^{b}_{\min} \) which only depends on the state-action pairs covered by the behavior policy \( \pi^{b} \) under the nominal model \( P^{0} \):

\[
P^{b}_{\min} := \min_{h,s,a,s'} \left\{ P^{0}_{h}(s'|s,a) : \ d^{b}_{h}(s,a) > 0, \ P^{0}_{h}(s'|s,a) > 0 \right\}.
\] (24)

In words, \( P^{b}_{\min} \) is the smallest positive state transition probability of the behavior policy \( \pi^{b} \) under the nominal kernel \( P^{0} \).

- Finally, let \( d^{b}_{\min} \) denote the smallest positive state-action occupancy distribution of the behavior policy \( \pi^{b} \) under the nominal model \( P^{0} \):

\[
d^{b}_{\min} := \min_{h,s,a} \left\{ d^{b}_{h}(s,a) : \ d^{b}_{h}(s,a) > 0 \right\}.
\] (25)

We are now positioned to present the performance guarantees of DRVI-LCB for robust offline RL.

**Theorem 1.** Given an uncertainty level \( \sigma > 0 \), suppose that the penalty terms in Algorithm 1 are chosen as (21) for sufficiently large \( c_{b} \). With probability at least \( 1 - \delta \), the output \( \hat{\pi} \) of Algorithm 1 obeys

\[
V_{1}^{*,\sigma}(\rho) - V_{1}^{\hat{\pi},\sigma}(\rho) \leq c_{0} \frac{H^{2}}{\sigma} \sqrt{\frac{SC^{*}_{\text{rob}} \log^{2}(KHS/\delta)}{P^{*}_{\min}K}},
\] (26)

as long as the number of episodes \( K \) satisfies

\[
K \geq \frac{c_{1} \log(KHS/\delta)}{d^{b}_{\min} P^{b}_{\min}},
\] (27)

where \( c_{0} \) and \( c_{1} \) are some sufficiently large universal constants.

Our theorem is the first to characterize the sample complexities of robust offline RL under partial coverage, to the best of our knowledge (cf. Table 2). Theorem 1 shows that DRVI-LCB finds an \( \epsilon \)-optimal robust policy as soon as the sample size \( T = KH \) is above the order of

\[
O\left(\frac{SC^{*}_{\text{rob}} H^{5}}{P^{*}_{\min} \sigma^{2} \epsilon^{2}}\right).
\] (28)

up to some logarithmic factor, where the burn-in cost is independent of the accuracy level \( \epsilon \). For sufficiently small accuracy level \( \epsilon \), this results in a sample complexity of

\[
O\left(\frac{SC^{*}_{\text{rob}} H^{5}}{P^{*}_{\min} \sigma^{2} \epsilon^{2}}\right).
\] (29)

Our theorem suggests that the sample efficiency of robust offline RL critically depends on the problem structure of the given RMDP (i.e. coverage of the optimal robust policy \( \pi^{*} \) as measured by \( P^{*}_{\min} \)) as well as the quality of the history dataset (as measured by \( C^{*}_{\text{rob}} \)). Given that \( C^{*}_{\text{rob}} \) can be as small as on the order of \( 1/S \), the sample complexity requirement can exhibit a much weaker dependency with the size of the state space \( S \).

On the flip side, to assess the optimality of Theorem 1, we develop an information-theoretic lower bound for robust offline RL as provided in the following theorem.

**Theorem 2.** For any \((H, S, C, P^{*}_{\min}, \sigma, \epsilon)\) obeying \( H \geq 2^{8}, C \geq 4/S, P^{*}_{\min} \in (0, \frac{1}{K}], \log(1/P^{*}_{\min}) - 6 \leq \sigma \leq \log(1/P^{\star}_{\min}) - 5, \) and \( \epsilon \leq \frac{H}{384 \epsilon^{5} \log(1/P^{*}_{\min})}, \) we can construct two finite-horizon RMDPs \( M_{0}, M_{1} \), an initial
state distribution $\rho$, and a batch dataset with $K$ independent sample trajectories each with length $H$ satisfying $2C \leq C_{\text{rob}}^* \leq 4C$, such that

$$\inf_{\hat{\pi}} \max \left\{ \mathbb{P}_0 \left( V_{1}^* - V_{2}^* (\rho) > \varepsilon \right), \mathbb{P}_1 \left( V_{1}^* - V_{2}^* (\rho) > \varepsilon \right) \right\} \geq \frac{1}{8},$$

provided that

$$T = KH \leq \frac{c_1 S C_{\text{rob}}^* H^3}{F_{\text{rob}}^{\star} \sigma^2 \varepsilon^2}.$$ 

Here, $c_1 > 0$ is some universal constant, the infimum is taken over all estimators $\hat{\pi}$, and $\mathbb{P}_0$ (resp. $\mathbb{P}_1$) denotes the probability when the RMDP is $M_0$ (resp. $M_1$).

Theorem 2 shows that no algorithm can succeed in finding an $\varepsilon$-optimal robust policy when the sample complexity falls below the order of

$$\Omega \left( \frac{S C_{\text{rob}}^* H^3}{F_{\text{rob}}^{\star} \sigma^2 \varepsilon^2} \right),$$

which confirms the near-optimality of DRVI-LCB up to a factor of $H^2$ ignoring logarithmic factors. Therefore, DRVI-LCB is the first provable algorithm for robust offline RL with a near-optimal sample complexity without requiring the stringent full coverage assumption.

4 Robust offline RL for discounted infinite-horizon RMDPs

In this section, we turn to the studies of robust offline RL for discounted infinite-horizon MDPs.

4.1 Backgrounds on discounted infinite-horizon RMDPs

Similar to the finite-horizon setting, we consider the discounted infinite-horizon robust MDPs (RMDPs) represented by $M_{\text{rob}} = \{S, A, \gamma, U^o(P^o), r\}$. Here, $S = \{1, 2, \cdots, S\}$ is the state space, $A = \{1, 2, \cdots, A\}$ is the action space, $\gamma \in [0, 1)$ is the discounted factor, and $r : S \times A \rightarrow [0, 1]$ is the intermediate reward function. Different from the standard MDPs, $U^o(P^o)$ denote the set of possible transition kernels within an uncertainty set centered around a nominal kernel $P^0 : S \times A \rightarrow \Delta(S)$ using the distance measured in terms of the KL divergence. In particular, given an uncertainty level $\sigma > 0$, the uncertainty set around $P^0$ is specified as

$$U^o(P^0) := \otimes U^o(P^0_{s,a}), \quad U^o(P^0_{s,a}) := \{ P_{s,a} \in \Delta(S) : \text{KL}( P_{s,a} \parallel P^0_{s,a}) \leq \sigma \},$$

where we denote a vector of the transition kernel $P$ or $P^0$ at $(s, a)$ respectively as $P_{s,a} := P(\cdot | s, a) \in \mathbb{R}^{1 \times S}$, $P^0_{s,a} := P^0(\cdot | s, a) \in \mathbb{R}^{1 \times S}$.

Policy and robust value/Q functions. A (possibly random) stationary policy $\pi : S \rightarrow \Delta(A)$ represents the selection rule of the agent, namely, $\pi(a | s)$ denote the probability of choosing $a$ in state $s$. With some abuse of notation, let $\pi(s)$ represent the action chosen by $\pi$ when $\pi$ is a deterministic policy. We define the robust value function $V^{\pi, \sigma}$ and robust Q-function $Q^{\pi, \sigma}$ respectively as

$$\forall (s, a) \in S \times A : \quad V^{\pi, \sigma}(s) := \inf_{P \in U^o(P^0)} V^{\pi, P}(s), \quad Q^{\pi, \sigma}(s, a) := \inf_{P \in U^o(P^0)} Q^{\pi, P}(s, a),$$

where the value function $V^{\pi, P}$ and Q-function $Q^{\pi, P}$ w.r.t. policy $\pi$ and transition kernel $P$ are defined respectively by

$$\forall s \in S : \quad V^{\pi, P}(s) := \mathbb{E}_{\pi, P} \left[ \sum_{t=0}^{\infty} \gamma^t r(s_t, a_t) \mid s_0 = s \right],$$

$$\forall (s, a) \in S \times A : \quad Q^{\pi, P}(s, a) := \mathbb{E}_{\pi, P} \left[ \sum_{t=0}^{\infty} \gamma^t r(s_t, a_t) \mid s_0 = s, a_0 = a \right],$$

where the expectation is taken over the randomness of the trajectory. In words, the robust value/Q functions characterize the worst case over all the instances in the uncertainty set.
Optimal policy and robust Bellman equation. Similar to the finite-horizon RMDPs, it is well-known that there exists at least one deterministic policy that maximizes the robust value function and Q-function simultaneously in the infinite-horizon setting as well (Iyengar, 2005; Nilim and El Ghaoui, 2005). With this in mind, we denote the optimal policy as \( \pi^* \) and the corresponding optimal robust value function (resp. optimal robust Q-function) as \( V^{\pi^*} \) (resp. \( Q^{\pi^*} \)), namely
\[
\forall s \in S : \quad V^{\pi^*}(s) := V^{\pi^*}(s) = \max_{\pi} V^{\pi^*}(s), \quad (34a)
\]
\[
\forall(s, a) \in S \times A : \quad Q^{\pi^*}(s, a) := Q^{\pi^*}(s, a) = \max_{\pi} Q^{\pi^*}(s, a). \quad (34b)
\]
In addition, we continue to admit the Bellman’s optimality principle, resulting in the following robust Bellman optimality equation:
\[
\forall(s, a) \in S \times A : \quad Q^{\pi^*}(s, a) = r(s, a) + \gamma \inf_{P \in \mathcal{U}(P^0)} V^{\pi^*}, \quad (35a)
\]
\[
\forall(s, a) \in S \times A : \quad Q^{\pi^*}(s, a) = r(s, a) + \gamma \inf_{P \in \mathcal{U}(P^0)} V^{\pi^*}. \quad (35b)
\]

Occupancy distributions. To begin, let \( \rho \) be some initial state distribution. We denote \( d^{\pi,P}(s \mid \rho) \) and \( d^{\pi,P}(s, a \mid \rho) \) respectively as the state occupancy distribution and the state-action occupancy distribution induced by policy \( \pi \), namely
\[
\forall s \in S : \quad d^{\pi,P}(s) := (1 - \gamma) \sum_{t=0}^{\infty} \gamma^t \mathbb{P}(s_t = s \mid s_0 \sim \rho, \pi, P), \quad (36a)
\]
\[
\forall(s, a) \in S \times A : \quad d^{\pi,P}(s, a) := (1 - \gamma) \sum_{t=0}^{\infty} \gamma^t \mathbb{P}(s_t = s \mid s_0 \sim \rho, \pi, P) \pi(a \mid s). \quad (36b)
\]
Here, the occupancy distributions are conditioned on \( s_0 \sim \rho \) and the sequence of actions and states are generated based on policy \( \pi \) and transition kernel \( P \). Next, applying (36) with \( \pi = \pi^* \), we adopt the following short-hand notation for the occupancy distributions associated with the optimal policy:
\[
\forall s \in S : \quad d^{*P}(s) := d^{\pi^*,P}(s), \quad (37a)
\]
\[
\forall(s, a) \in S \times A : \quad d^{*P}(s, a) := d^{\pi^*,P}(s, a) = d^{\pi^*,P}(s) \mathbb{1}(a = \pi^*(s)). \quad (37b)
\]

4.2 Data collection and constructing the empirical MDP
Suppose that we observe a batch/history dataset \( \mathcal{D} = \{(s_i, a_i, s'_i)\}_{1 \leq i \leq N} \) consisting of \( N \) sample transitions. These transitions are independently generated, where the state-action pair is drawn from some behavior distribution \( d^b \in \Delta(S \times A) \), followed by a next state drawn over the nominal transition kernel \( P^0 \), i.e.,
\[
(s_i, a_i) \overset{i.i.d.}{\sim} d^b \quad \text{and} \quad s'_i \overset{i.i.d.}{\sim} P^0(\cdot \mid s_i, a_i), \quad 1 \leq i \leq N. \quad (38)
\]
Similar to Assumption 1, we design the following robust single-policy clipped concentrability assumption tailored for infinite-horizon RMDPs to characterize the quality of the history dataset.

Assumption 2 (Robust single-policy clipped concentrability for infinite-horizon MDPs). The behavior policy of the history dataset \( \mathcal{D} \) satisfies
\[
\max_{(s,a,P) \in S \times A \times \mathcal{U}(P^0)} \frac{\min \{d^{*P}(s,a), \frac{1}{N} \}}{d^b(s,a)} \leq C_{rob}^* \quad (39)
\]
for some finite quantity \( C_{rob}^* \in \left[ \frac{1}{S}, \infty \right) \). Following the convention \( 0/0 = 0 \), we denote \( C_{rob}^* \) to be the smallest quantity satisfying (39), and refer to it as the robust single-policy clipped concentrability coefficient.

Remark 2. Similar to Remark 1, we can bound \( C_{rob}^* \leq A \) when the batch dataset is generated using a simulator (Panaganti and Kalathil, 2022; Yang et al., 2021). By combining this bound of \( C_{rob}^* \) with the theoretical guarantees developed momentarily in Theorem 3, we obtain the comparison in Table 2.
Algorithm 2 Robust value iteration with LCB (DRVI-LCB) for infinite-horizon RMDPs.

**input:** a dataset $D$; reward function $r$; uncertainty level $\sigma$; number of iterations $M$.

**initialization:** $\hat{Q}_0(s,a) = 0$, $\hat{V}_0(s) = 0$ for all $(s,a) \in S \times A$.

Compute the empirical nominal transition kernel $\hat{P}^0$ according to (42);
Compute the penalty term $b(s,a)$ according to (46);
for $m = 1, 2, \cdots, M$ do
  for $s \in S, a \in A$ do
    Set $\hat{Q}_m(s,a)$ according to (49);
  for $s \in S$ do
    Set $\hat{V}_m(s) = \max_a \hat{Q}_m(s,a)$;

**output:** $\hat{\pi}$ s.t. $\hat{\pi}(s) = \arg\max_a \hat{Q}_M(s,a)$ for all $s \in S$.

Armed with these, we are ready to introduce the goal in the infinite-horizon setting. Given the history dataset $D$ obeying Assumption 2, for some target accuracy $\varepsilon > 0$, we aim to find a near-optimal robust policy $\hat{\pi}$, which satisfies

$$V^{\hat{\pi},\sigma}(\rho) \geq V^\star,\sigma(\rho) - \varepsilon$$

in a sample-efficient manner for some initial state distribution $\rho$.

**Building an empirical nominal MDP** Recalling that we have $N$ independent samples in the dataset $D = \{(s_i, a_i, s'_i)\}_{1 \leq i \leq N}$. First, we denote $N(s,a)$ as the total number of sample transitions from any state-action pair $(s,a)$ as

$$N(s,a) := \sum_{i=1}^{N} \mathbb{1}\{(s_i, a_i) = (s,a)\}. \quad (41)$$

Armed with $N(s,a)$, we construct the empirical estimate $\hat{P}^0$ of the nominal kernel $P^0$ by the visiting frequencies of state-action pairs as follows:

$$\hat{P}^0(s'|s,a) := \begin{cases} \frac{1}{N(s,a)} \sum_{i=1}^{N} \mathbb{1}\{(s_i, a_i, s'_i) = (s,a, s')\}, & \text{if } N(s,a) > 0 \\ 0, & \text{else} \end{cases} \quad (42)$$

for any $(s,a, s') \in S \times A \times S$.

### 4.3 DRVI-LCB for discounted infinite-horizon RMDPs

With the estimate $\hat{P}^0$ of the nominal transition kernel $P^0$ in hand, we are positioned to introduce our algorithm DRVI-LCB for infinite-horizon RMDPs, which bears some similarity with the finite-horizon version (cf. Algorithm 1), by taking the uncertainties of the value estimates into consideration throughout the value iterations. The procedure is summarized in Algorithm 2.

**The pessimistic robust Bellman operator.** At the core of DRVI-LCB is a pessimistic variant of the classical robust Bellman operator in the infinite-horizon setting (Iyengar, 2005; Nilim and El Ghaoui, 2005; Zhou et al., 2021), denoted as $T^\sigma(\cdot) : \mathbb{R}^{S,A} \to \mathbb{R}^{S,A}$, which we recall as follows:

$$\forall(s,a) \in S \times A : \quad T^\sigma(Q)(s,a) := r(s,a) + \gamma \inf_{P \in U^\sigma(P^0_{s,a})} PV, \quad \text{with} \quad V(s) := \max_a Q(s,a). \quad (43)$$

Encouragingly, the robust Bellman operator shares the nice $\gamma$-contraction property of the standard Bellman operator, ensuring fast convergence of robust value iteration by applying the robust Bellman operator (43)
recursively. In the robust offline setting, instead of recursing using the population robust Bellman operator, we need to construct a pessimistic variant of the robust Bellman operator \( \hat{T}_{pe}^\sigma(\cdot) \) w.r.t. the empirical nominal kernel \( \hat{P}^0 \) as follows:

\[
\forall (s, a) \in S \times A:\quad \hat{T}_{pe}^\sigma(Q)(s, a) = \max \left\{ r(s, a) + \gamma \inf_{P \in U^\sigma(\hat{P}^0)} PV - b(s, a), 0 \right\}, \tag{44}
\]

where \( b(s, a) \) denotes the penalty term that measures the data-dependent uncertainty of the value estimates.

To specify the tailored penalty term \( b(s, a) \) in (44), we first introduce an additional term

\[
\forall (s, a) \in S \times A:\quad \hat{P}_{\min}(s, a) := \min_s \left\{ \hat{P}^0(s' \mid s, a) : \hat{P}^0(s' \mid s, a) > 0 \right\}, \tag{45}
\]

which in words represents the smallest positive transition probability of the estimated nominal kernel \( \hat{P}^0(s' \mid s, a) \). Then for some \( \delta \in (0, 1) \), some universal constant \( c_\delta > 0 \), \( b(s, a) \) is defined as

\[
b(s, a) = \begin{cases} \min \left\{ c_\delta \sigma(1-\gamma) \left( \log \left( \frac{2(1-\gamma)N^3}{4(1-\gamma)N} \right) \right) + \frac{4}{\sigma(1-\gamma)}, \frac{1}{1-\gamma}, \frac{2}{\sigma N} \right\}, & \text{if } N(s, a) > 0, \\ \frac{1}{1-\gamma} + \frac{2}{\sigma N}, & \text{otherwise}. \end{cases}
\]

As shall be illuminated, our proposed pessimistic robust Bellman operator \( \hat{T}_{pe}^\sigma(\cdot) \) (cf. (44)) plays an important role in DRVI-LCB. Encouragingly, despite the additional data-driven penalty term \( b(s, a) \), it still enjoys the celebrated \( \gamma \)-contraction property below, whose proof is postponed to Appendix C.1.

**Lemma 2 (\( \gamma \)-Contraction).** For any \( \gamma \in [0, 1) \), the operator \( \hat{T}_{pe}^\sigma(\cdot) \) (cf. (44)) is a \( \gamma \)-contraction w.r.t. \( \| \cdot \|_\infty \). Namely, for any \( Q_1, Q_2 \in \mathbb{R}^{SA} \) s.t. \( Q_1(s, a), Q_2(s, a) \in [0, \frac{1}{1-\gamma}] \) for all \( (s, a) \in S \times A \), one has

\[
\left\| \hat{T}_{pe}^\sigma(Q_1) - \hat{T}_{pe}^\sigma(Q_2) \right\|_\infty \leq \gamma \| Q_1 - Q_2 \|_\infty. \tag{47}
\]

Additionally, there exists a unique fixed point \( \hat{Q}_{pe}^\sigma \) of the operator \( \hat{T}_{pe}^\sigma(\cdot) \) obeying \( 0 \leq \hat{Q}_{pe}^\sigma(s, a) \leq \frac{1}{1-\gamma} \) for all \( (s, a) \in S \times A \).

**Our algorithm DRVI-LCB for infinite-horizon robust offline RL.** Armed with the \( \gamma \)-contraction property of the pessimistic robust Bellman operator \( \hat{T}_{pe}^\sigma(\cdot) \), we are positioned to introduce DRVI-LCB for infinite-horizon RMDPs, summarized in Algorithm 2. Specifically, DRVI-LCB can be seen as a value iteration algorithm w.r.t. \( \hat{T}_{pe}^\sigma(\cdot) \) (cf. (44)), whose update rule at the \( m \)-th iteration can be formulated as

\[
\hat{Q}_m(s, a) = \hat{T}_{pe}^\sigma(\hat{Q}_{m-1})(s, a) = \max \left\{ r(s, a) + \gamma \inf_{P \in U^\sigma(\hat{P}^0)} PV - b(s, a), 0 \right\}, \tag{48}
\]

and \( \hat{V}_m(s) = \max_a \hat{Q}_m(s, a) \) for all \( m = 1, 2, \cdots, M \). In view of strong duality (Hu and Hong, 2013), the above convex problem can be translated into a dual formulation, leading to the following equivalent update rule:

\[
\hat{Q}_m(s, a) = \max \left\{ r(s, a) + \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{pe}(\hat{V}_{m-1}^0) \cdot \exp \left( \frac{-\hat{V}_{m-1}}{\lambda} \right) \right) - \lambda \sigma \right\} - b(s, a), 0 \right\}, \tag{49}
\]

which can be solved efficiently (Iyengar, 2005; Panaganti and Kalathil, 2022; Yang et al., 2021) as a one-dimensional optimization problem.

To finish the description, we initialize the estimates of Q-function \( \hat{Q}_0 \) and value function \( \hat{V}_0 \) to be zero and output the greedy policy of the final Q-estimates \( \hat{Q}_M \) as the final policy \( \hat{\pi} \), namely,

\[
\hat{\pi}(s) = \arg\max_a \hat{Q}_M(s, a) \quad \text{for all } s \in S. \tag{50}
\]
It turns out that the iterates \( \{\hat{Q}_m\}_{m \geq 0} \) of DRVI-LCB converge linearly to the fixed point \( \hat{Q}_{pe}^{*,\sigma} \) owing to the nice \( \gamma \)-contraction property outlined in Lemma 2. This fact is summarized in the following lemma, whose proof is postponed to Appendix C.2.

**Lemma 3.** Let \( \hat{Q}_0 = 0 \). The iterates of Algorithm 2 obey

\[
\forall m \geq 0 : \quad \hat{Q}_m \leq \hat{Q}_{pe}^{*,\sigma} \quad \text{and} \quad \|\hat{Q}_m - \hat{Q}_{pe}^{*,\sigma}\|_\infty \leq \gamma^m .
\]

### 4.4 Performance guarantees

Before introducing the main theorems, we first define several essential metrics.

- \( d_{\min}^b \): the smallest positive entry of the distribution \( d^b \), i.e.,
  \[
  d_{\min}^b := \min_{s,a} \{ d^b(s,a) : d^b(s,a) > 0 \} .
  \]

- \( P_{\min}^b \): the smallest positive state transition probability under the nominal kernel \( P^0 \) in the region covered by dataset \( D \), i.e.,
  \[
  P_{\min}^b := \min_{s,a,s'} \left\{ P^0(s' | s,a) : d^b(s,a) > 0, P^0(s' | s,a) > 0 \right\} .
  \]

Note that \( P_{\min}^b \) is determined only by the state-action pairs covered by the batch dataset \( D \).

- \( P_{\min}^* \): the smallest positive state transition probability of the optimal robust policy \( \pi^* \) under the nominal kernel \( P^0 \), namely
  \[
  P_{\min}^* := \min_{s,s'} \left\{ P^0(s' | s,\pi^*(s)) : P^0(s' | s,\pi^*(s)) > 0 \right\} .
  \]

We also note that \( P_{\min}^* \) is determined only by the state-action pairs covered by the optimal robust policy \( \pi^* \) under the nominal model \( P^0 \).

We are now positioned to introduce the sample complexity upper bound of DRVI-LCB, together with the minimax lower bound, for solving infinite-horizon RMDPs. First, we present the performance guarantees of DRVI-LCB for robust offline RL in the infinite-horizon case, with the proof deferred to Appendix C.3.

**Theorem 3.** Let \( c_0 \) and \( c_1 \) be some sufficiently large universal constants. Given an uncertainty level \( \sigma > 0 \), suppose that the penalty terms in Algorithm 2 are chosen as (46) for sufficiently large \( c_0 \). With probability at least \( 1 - \delta \), the output \( \hat{\pi} \) of Algorithm 2 obeys

\[
V^{\pi^*,\sigma}(\rho) - V^{\hat{\pi},\sigma}(\rho) \leq \frac{c_0}{\sigma(1-\gamma)^2} \sqrt{\frac{SC_{\text{rob}}^* \log^2 \left( \frac{(1+\sigma)NS}{(1-\gamma)\delta} \right)}{P_{\min}^* N}},
\]

as long as the number of samples \( N \) satisfies

\[
N \geq \frac{c_1 \log(\frac{NS}{\delta})}{d_{\min}^b P_{\min}^b} .
\]

The result directly indicates that DRVI-LCB can finds an \( \varepsilon \)-optimal policy as long as the sample size in dataset \( D \) exceeds the order of (ignoring logarithmic factors)

\[
\frac{SC_{\text{rob}}^*}{P_{\min}^* (1-\gamma) \varepsilon_2} + \frac{1}{d_{\min}^b P_{\min}^b} ,
\]

\( \varepsilon \)-dependent burn-in cost.
Note that the burn-in cost is independent with the accuracy level $\varepsilon$, which tells us that the sample complexity is no more than
\[
\widetilde{O}\left(\frac{SC_{\text{rob}}^*}{P_{\text{min}}^*(1-\gamma)^4\sigma^2\varepsilon^2}\right)
\] (58)
as long as $\varepsilon$ is small enough. The sample complexity of DRVI-LCB still dramatically outperforms prior works under full coverage, which has been compared in detail in Section 1.2 (cf. Table 2). In particular, our sample complexity produces an exponential improvement over Panaganti and Kalathil (2022); Zhou et al. (2021) in terms of the dependency with the effective horizon $\frac{1}{1-\gamma}$, which is especially significant for long-horizon problems. Compared with Yang et al. (2021), our sample complexity is better by at least a factor of $S/P_{\text{min}}^*$.

To achieve the claimed bound, we resort to a delicate technique called the leave-one-out analysis (Agarwal et al., 2020; Li et al., 2022, 2020), by carefully designing an auxiliary set of RMDPs to decouple the statistical dependency introduced across the iterates of pessimistic robust value iteration. This is the first time that the leave-one-out analysis is applied to understanding the sample efficiency of model-based robust RL algorithms, which is of potential independent interest to tighten the sample complexity of other robust RL problems.

To complement the upper bound, we develop an information-theoretic lower bound for robust offline RL as provided in the following theorem whose proof can be found in Appendix C.4.

**Theorem 4.** For any $(S, P_{\text{min}}^*, C_{\text{rob}}^*, \gamma, \sigma, \varepsilon)$ obeying $\frac{1}{1-\gamma} \geq 2e^8$, $P_{\text{min}}^* \in (0, 1-\gamma]$, $S \geq \log \left(\frac{1}{P_{\text{min}}^*}\right)$, $C_{\text{rob}}^* \geq 8/S$, $\varepsilon \leq \frac{1}{384e^6(1-\gamma)\log \left(\frac{1}{P_{\text{min}}^*}\right)}$, and $\log \left(\frac{1}{P_{\text{min}}^*}\right) - 6 \leq \sigma \leq \log \left(\frac{1}{P_{\text{min}}^*}\right) - 5$, we can construct two infinite-horizon RMDPs $\mathcal{M}_0, \mathcal{M}_1$, an initial state distribution $\rho$, and a batch dataset with $N$ independent samples, such that
\[
\inf_{\tilde{\pi}} \max\left\{P_0(V^*,\sigma(\rho) - V^{\tilde{\pi}},\sigma(\rho) > \varepsilon), P_1(V^*,\sigma(\rho) - V^{\tilde{\pi}},\sigma(\rho) > \varepsilon)\right\} \geq \frac{1}{8},
\]
provided that
\[
N \leq \frac{c_1SC_{\text{rob}}^*}{P_{\text{min}}^*(1-\gamma)^2\sigma^2\varepsilon^2}.
\]
Here, $c_1 > 0$ is some universal constant, the infimum is taken over all estimators $\tilde{\pi}$, and $P_0$ (resp. $P_1$) denotes the probability when the RMDP is $\mathcal{M}_0$ (resp. $\mathcal{M}_1$).

The above theorem suggests that there exists some RMDP such that no algorithm can find an $\varepsilon$-optimal policy if the sample complexity is below the order of
\[
\Omega\left(\frac{SC_{\text{rob}}^*}{P_{\text{min}}^*(1-\gamma)^2\sigma^2\varepsilon^2}\right),
\]
which directly confirms that DRVI-LCB is near-optimal up to a polynomial factor of the effective horizon length $\frac{1}{1-\gamma}$ (cf. (57)). To the best of our knowledge, DRVI-LCB is the first provable algorithm with near-optimal sample complexity for infinite-horizon robust offline RL. Moreover, the requirement imposed on the history dataset is also much weaker than prior literature on robust offline RL (Yang et al., 2021; Zhou et al., 2021), without the need of full coverage of the state-action space.

5 Numerical experiments

We conduct experiments on the gambler’s problem (Sutton and Barto, 2018; Zhou et al., 2021) to evaluate the performance of the proposed algorithm DRVI-LCB, with comparisons to both the robust value iteration algorithm DRVI without pessimism (Panaganti and Kalathil, 2022). Our code can be accessed at:

[https://github.com/Laixishi/Robust-RL-with-KL-divergence](https://github.com/Laixishi/Robust-RL-with-KL-divergence).
In the gambler’s game (Sutton and Barto, 2018; Zhou et al., 2021), a gambler bets on a sequence of coin flips, winning the stake with heads and losing with tails. Starting from some initial balance, the game ends when the gambler’s balance either reaches 50 or 0, or the total number of bets $H$ is hit. This problem can be formulated as an episodic finite-horizon MDP, with a state space $\mathcal{S} = \{0, 1, \cdots, 50\}$ and the associated possible actions $a \in \{0, 1, \cdots, \min\{s, 50 - s\}\}$ at state $s$. Here, we set the horizon length $H = 100$. Moreover, the parameter of the transition kernel, which is the probability of heads for the coin flip, is fixed as $p_{\text{head}}$ and remains the same in all time steps $h \in [H]$. The reward is set as 1 when the state reaches $s = 50$ and 0 for all other cases. In addition, suppose the initial state (i.e., the gambler’s initial balance) distribution $\rho$ is taken uniformly at random within $\mathcal{S}$. Throughout the experiments, we utilize a history dataset with $N$ samples per state-action pair and time step, which is generated from a nominal MDP with $p_{0_{\text{head}}} = 0.6$.

**Results and discussions.** First, we evaluate the performance of the learned policy $\hat{\pi}$ using our proposed method DRVI-LCB with comparison to robust value iteration (DRVI) without pessimism, where we fix the uncertainty level $\sigma = 0.1$ for learning the robust optimal policy. The experiments are repeated 10 times with the average and standard deviations reported. To begin with, Figure 1(a) plots the sub-optimality value gap $V^*_1(s) - V^{\pi\cdot\sigma}_1(s)$ for every $s \in \mathcal{S}$, when a sample size $N = 100$ is used to learn the robust policies. It is shown that DRVI-LCB outperform the baseline DRVI uniformly over the state space when the sample size is small, corroborating the benefit of pessimism in the sample-starved regime. Furthermore, Figure 1(b) shows the sub-optimality gap $V^*_1(\rho) - V^{\pi\cdot\sigma}_1(\rho)$ with varying sample sizes $n = 100, 300, 1000, 3000, 5000$, where the initial test distribution $\rho$ is generated randomly. While the performance of DRVI-LCB and DRVI both improves with the increase of the sample size, the proposed algorithm DRVI-LCB achieves much better performance with fewer samples.

Finally, to corroborate the benefit of distributional robustness, we evaluate the performance of the policy learned from $N = 1000$ samples using DRVI-LCB on perturbed environments with varying model parameters $p_{\text{head}} \in [0.25, 0.75]$. We measure the practical performance based on the ratio of winning (i.e., reaching the state $s = 50$) calculated from 3000 episodes. Figure 1(c) illustrates the ratio of winning against the test probability of heads for the policies learned from DRVI-LCB with $\sigma = 0.01$ and $\sigma = 0.2$, which are benchmarked against the non-robust optimal policy of the nominal MDP using the exact model. It can be seen that the policies learned from DRVI-LCB deviate from the non-robust optimal policy as $\sigma$ increases, which achieves better worst-case rates of winning across a wide range of perturbed environments. On the other end, while the non-robust policy maximizes the performance when the test environment is close to the history one used for training, its performance degenerates to be much worse than the robust policies when the probability of heads is mismatched significantly, especially when $p_{\text{head}}$ drops below, say around, 0.5.

---

2The probability distribution vector $\rho \in \Delta(\mathcal{S})$ is generated as $\rho(s) = u_s / \sum_{s \in \mathcal{S}} u_s$, where $u_s$ is drawn independently from a uniform distribution.
6 Conclusion

To accommodate both model robustness and sample efficiency, this paper proposes a distributionally robust model-based algorithm for offline RL with the principle of pessimism. We study the finite-sample complexity of the proposed algorithm DRVI-LCB, and establishes its near-optimality with a matching information-theoretic lower bound. Numerical experiments are provided to demonstrate the efficacy of the proposed algorithm. To the best our knowledge, this provides the first provably near-optimal robust offline RL algorithm that learns under model perturbation and partial coverage. This work opens up several interesting directions; for example, can we design provably efficient model-free algorithms for robust offline RL with partial coverage? In addition, can we extend the algorithm design to the multi-agent setting in a scalable manner? Moreover, it is possible to extend our framework to handle uncertainty sets defined using other distances such as the chi-square distance and the total variation distance in a similar fashion. We leave these questions to future investigations.

A Preliminaries

Before starting, let us introduce some additional notation useful throughout the theoretical analysis. Let $\text{ess inf } X$ denote the essential infimum of a function/variable $X$.

A.1 Properties of the robust Bellman operator

To begin with, we introduce the following strong duality lemma which is widely used in distributionally robust optimization when the uncertainty set is defined with respect to the KL divergence.

**Lemma 4** ((Hu and Hong, 2013), Theorem 1). Suppose $f(x)$ has a finite moment generating function in some neighborhood around $x = 0$, then for any $\sigma > 0$ and a nominal distribution $P^0$, we have

$$\sup_{P \in U^\sigma(P^0)} \mathbb{E}_{X \sim P}[f(X)] = \inf_{\lambda \geq 0} \left\{ \lambda \log \mathbb{E}_{X \sim P^0} \left[ \exp \left( \frac{f(X)}{\lambda} \right) \right] + \lambda \sigma \right\}. \quad (59)$$

Armed with the above lemma, it is easily verified that for any positive constant $M$ and a nominal distribution vector $P^0 \in \mathbb{R}^{1 \times S}$ supported over the state space $S$, if $X(s) \in [0, M]$ for all $s \in S$, then

$$\inf_{P \in U^\sigma(P^0)} P X = \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( P^0 \exp \left( -\frac{X}{\lambda} \right) \right) - \lambda \sigma \right\}. \quad (60)$$

For convenience, we introduce the following lemma, paraphrased from Zhou et al. (2021, Lemma 4) and its proof, to further characterize several essential properties of the optimal dual value.

**Lemma 5** ((Zhou et al., 2021)). Let $X \sim P$ be a bounded random variable with $X \in [0, M]$. Let $\sigma > 0$ be any uncertainty level and the corresponding optimal dual variable be

$$\lambda^* \in \arg \max_{\lambda \geq 0} f(\lambda, P), \quad \text{where } f(\lambda, P) := \left\{ -\lambda \log \mathbb{E}_{X \sim P} \left[ \exp \left( -\frac{X}{\lambda} \right) \right] - \lambda \sigma \right\}. \quad (61)$$

Then the optimal value $\lambda^*$ obeys

$$\lambda^* \in \left[ 0, \frac{M}{\sigma} \right], \quad (62)$$

where $\lambda^* = 0$ if and only if

$$\log \left( \mathbb{P}(X = \text{ess inf } X) \right) + \sigma \geq 0. \quad (63)$$

Moreover, when $\lambda^* = 0$, we have

$$\lim_{\lambda \to 0} f(\lambda, P) = \lim_{\lambda \to 0} \left\{ -\lambda \log \mathbb{E}_{X \sim P} \left[ \exp \left( -\frac{X}{\lambda} \right) \right] - \lambda \sigma \right\} = \text{ess inf } X. \quad (64)$$

A.2 Concentration inequalities

In light of Lemma 5 (cf. 64), we are interested in comparing the values of $\text{ess inf } X$ when $X$ is drawn from the population nominal distribution or its empirical estimate. This is supplied by the following lemma from Zhou et al. (2021).

**Lemma 6** ((Zhou et al., 2021)). Let $X \sim P$ be a discrete bounded random variable with $X \in [0, M]$. Let $P_n$ denote the empirical distribution constructed from $n$ independent samples $X_1, X_2, \cdots, X_n$, and let $\hat{X} \sim P_n$. Denote $P_{\min, X}$ as the smallest positive probability $P_{\min, X} := \min \{ \mathbb{P}(X = x) : x \in \text{supp}(X) \}$, where $\text{supp}(X)$ is the support of $X$. Then for any $\delta \in (0, 1)$, with probability at least $1 - \delta$, we have

$$\min_{i \in [n]} X_i = \text{ess inf } \hat{X} = \text{ess inf } X, \quad (65)$$

as long as

$$n \geq - \frac{\log(2/\delta)}{\log(1 - P_{\min, X})}. \quad (66)$$

22
We next gather a few elementary facts about the Binomial distribution, which will be useful throughout the proof.

**Lemma 7** (Chernoff’s inequality). Suppose $N \sim \text{Binomial}(n,p)$, where $n \geq 1$ and $p \in [0, 1)$. For some universal constant $c_f > 0$, we have

$$
P(|N/n - p| \geq pt) \leq \exp \left(-c_f n p t^2\right), \quad \forall t \in [0, 1].
$$

(67)

**Lemma 8** ((Shi et al., 2022, Lemma 8)). Suppose $N \sim \text{Binomial}(n,p)$, where $n \geq 1$ and $p \in [0, 1)$. For any $\delta \in (0, 1)$, we have

$$N \begin{cases} np & \text{if } np \geq 8 \log\left(\frac{1}{\delta}\right), \\ 2e^2 \log\left(\frac{1}{\delta}\right) & \text{if } np \leq 2 \log\left(\frac{1}{\delta}\right) \end{cases}$$

(68a) hold with probability at least $1 - 4\delta$.

**A.3 Kullback-Leibler (KL) divergence**

We next introduce some useful facts about the Kullback-Leibler (KL) divergence for two distributions $P$ and $Q$, denoted as $\text{KL}(P \parallel Q)$. Denoting $\text{Ber}(p)$ (resp. $\text{Ber}(q)$) as the Bernoulli distribution with mean $p$ (resp. $q$), we introduce

$$\text{KL}(\text{Ber}(p) \parallel \text{Ber}(q)) := p \log\frac{p}{q} + (1 - p) \log\frac{1 - p}{1 - q},$$

(69)

which represents the KL divergence from $\text{Ber}(p)$ to $\text{Ber}(q)$. We now introduce the following lemma.

**Lemma 9.** For any $p, q \in \left[\frac{1}{2}, 1\right]$ and $p > q$, it holds that

$$\text{KL}(\text{Ber}(p) \parallel \text{Ber}(q)) \leq \text{KL}(\text{Ber}(q) \parallel \text{Ber}(p)) \leq \frac{(p - q)^2}{p(1 - p)}.$$

(70)

Moreover, for any $0 \leq x < y < q$, it holds

$$\text{KL}(\text{Ber}(x) \parallel \text{Ber}(q)) > \text{KL}(\text{Ber}(y) \parallel \text{Ber}(q)).$$

(71)

**Proof.** The first half of this lemma is proven in Li et al. (2022, Lemma 10). For the latter half, it follows from that the function

$$f(x, q) := \text{KL}(\text{Ber}(x) \parallel \text{Ber}(q))$$

is monotonically decreasing for all $x \in (0, q]$, since its derivative with respect to $x$ satisfies $\frac{df(x,q)}{dx} = \log\frac{x}{q} + \log\frac{1-x}{1-q} < 0$.

**B Analysis: episodic finite-horizon RMDPs**

**B.1 Proof of Theorem 1**

Before starting, we introduce several additional notation that will be useful in the analysis. First, we denote the state-action space covered by the behavior policy $\pi^b$ in the nominal model $P^0$ as

$$C^b = \{(h, s, a) : d_h^b(s, a) > 0\}.$$

(72)

Moreover, we recall the definition in (22) and define a similar one based on the exact nominal model $P^0$ as

$$P_{\text{min}, h}(s, a) := \min_{s'} \left\{ P_h^0(s' | s, a) : P_h^0(s' | s, a) > 0 \right\}.$$ 

(73)
Clearly, by comparing with the definitions (23) and (24), it holds that
\[
P^\ast_{\min} = \min_{h,s} P_{\min,h}(s, \pi_h^\ast(s)), \quad P^b_{\min} = \min_{(h,s,a) \in \mathcal{C}} P_{\min,h}(s,a). \tag{74}
\]

For any time step \(h \in [H]\), we denote the set of possible state occupancy distributions associated with the optimal policy \(\pi^\ast\) in a model within the uncertainty set \(P \in \mathcal{U}^\sigma(P^0)\) as
\[
\mathcal{D}_h^\ast = \left\{ \left[ d_h^P(s) \right]_{s \in \mathcal{S}} : P \in \mathcal{U}^\sigma(P^0) \right\} = \left\{ \left[ d_h^P(s, \pi_h^\ast(s)) \right]_{s \in \mathcal{S}} : P \in \mathcal{U}^\sigma(P^0) \right\}, \tag{75}
\]
where the second equality is due to the fact that \(\pi^\ast\) is chosen to be deterministic.

With these in place, the proof of Theorem 1 is separated into several key steps, as outlined below.

**Step 1: establishing the pessimism property.** To achieve this claim, we heavily count on the following lemma whose proof can be found in Appendix B.2.

**Lemma 10.** Instate the assumptions in Theorem 1. Then for all \((h,s,a) \in [H] \times \mathcal{S} \times \mathcal{A}\), consider any vector \(V \in \mathbb{R}^\mathcal{S}\) independent of \(\bar{P}_{h,s,a}^0\) obeying \(\|V\|_\infty \leq H\). With probability at least \(1 - \delta\), one has
\[
\inf_{P \in \mathcal{U}^\sigma(P^0)} V_P - \inf_{P \in \mathcal{U}^\sigma(P^0)} V_P \leq b_h(s,a) \tag{76}
\]
where \(b_h(s,a)\) given in (21). Moreover, for all \((h,s,a) \in \mathcal{C}^b\), with probability at least \(1 - \delta\), one has
\[
\frac{P_{\min,h}(s,a)}{8 \log(KHS/\delta)} \leq \bar{P}_{\min,h}(s,a) \leq e^2 P_{\min,h}(s,a). \tag{77}
\]

Armed with the above lemma, with probability at least \(1 - \delta\), we shall show the following relation holds
\[
\forall(s,a,h) \in \mathcal{S} \times \mathcal{A} \times [H + 1] : \quad \bar{Q}_{h}(s,a) \leq \bar{Q}_{h+1}^\pi(s,a), \quad \bar{V}_{h}(s) \leq \bar{V}_{h+1}^\pi(s), \tag{78}
\]
which means that \(\bar{Q}_{h}\) (resp. \(\bar{V}_{h}\)) is a pessimistic estimate of \(Q_{h}^\pi\) (resp. \(V_{h}^\pi\)). Towards this, it is easily verified that the latter assertion concerning \(V_{h}^\pi\) is implied by the former, since
\[
\bar{V}_{h}(s) = \max_a \bar{Q}_{h}(s,a) \leq \max_a Q_{h}^\pi(s,a) = V_{h}^\pi(s). \tag{79}
\]

Therefore, the remainder of this step focuses on verifying the former assertion in (78) by induction.

- To begin, the claim (78) holds at the base case when \(h = H+1\), by invoking the trivial fact \(\bar{Q}_{H+1}(s,a) = Q_{H+1}^\pi(s,a) = 0\).
- Then, suppose that \(\bar{Q}_{h+1}(s,a) \leq Q_{h+1}^\pi(s,a)\) holds for all \((s,a) \in \mathcal{S} \times \mathcal{A}\) at some time step \(h \in [H]\), it boils down to show \(\bar{Q}_{h}(s,a) \leq Q_{h}^\pi(s,a)\).

By the update rule of \(\bar{Q}_{h}(s,a)\) in Algorithm 1 (cf. line 3.2), the above relation holds immediately if \(\bar{Q}_{h}(s,a) = 0\) since \(\bar{Q}_{h}(s,a) = 0 \leq Q_{h}^\pi(s,a)\). Otherwise, \(\bar{Q}_{h}(s,a)\) is updated via
\[
\bar{Q}_{h}(s,a) = r_h(s,a) + \sup_{\lambda > 0} \left\{-\lambda \log \left( ar{P}_{h,s,a}^0 \cdot \exp \left( \frac{-\bar{V}_{h+1}}{\lambda} \right) \right) - \lambda \sigma \right\} - b_h(s,a)
\]
\[
\overset{(i)}{=} r_h(s,a) + \inf_{P \in \mathcal{U}^\sigma(\bar{P}_{h,s,a}^0)} \bar{P}_{h+1} - b_h(s,a)
\]
\[
\leq r_h(s,a) + \inf_{P \in \mathcal{U}^\sigma(\bar{P}_{h,s,a}^0)} \bar{P}_{h+1} + \inf_{P \in \mathcal{U}^\sigma(\bar{P}_{h,s,a}^0)} \bar{P}_{h+1} - \inf_{P \in \mathcal{U}^\sigma(\bar{P}_{h,s,a}^0)} \bar{P}_{h+1} - b_h(s,a)
\]

24
and consequently, 

\[ (ii) \quad r_h(s, a) + \inf_{P \in U^r(p_{h,s,a}^0)} \mathcal{P}V_{h+1}^v, \sigma \geq 0 = Q_{h}^{v, \sigma}(s, a), \] 

where (i) rewrites the update rule back to its primal form (cf. (18)), (ii) holds by applying (76) with the condition (27) satisfied and the induction hypothesis \( \hat{V}_{h+1} \leq V_{h+1}^v, \sigma \), and lastly, (iii) follows by the robust Bellman consistency equation (8).

Putting them together, we have verified the claim (78) by induction.

**Step 2: bounding \( V_h^v, \sigma(s) - V_h^v, \sigma(s) \).** With the pessimism property (78) in place, we observe that the following relation holds

\[ 0 \leq V_h^v, \sigma(s) - V_h^{\hat{v}, \sigma}(s) - \hat{V}_h(s) \leq Q_h^v, \sigma(s, \pi_h^*)(s) - \hat{Q}_h(s, \pi_h^*(s)), \] 

where the last inequality follows from \( \hat{Q}_h(s, \pi_h^*(s)) \leq \max_a \hat{Q}_h(s, a) = \hat{V}_h(s) \). Then, by the robust Bellman optimality equation in (9) and the primal version of the update rule (cf. (18))

\[
\begin{align*}
Q_h^v, \sigma(s, \pi_h^*(s)) &= r_h(s, \pi_h^*(s)) + \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}V_{h+1}^v, \\
\hat{Q}_h(s, \pi_h^*(s)) &= r_h(s, \pi_h^*(s)) + \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1} - b_h(s, \pi_h^*(s)),
\end{align*}
\]

we arrive at

\[
V_h^v, \sigma(s) - \hat{V}_h(s) \leq Q_h^v, \sigma(s, \pi_h^*(s)) - \hat{Q}_h(s, \pi_h^*(s))
\]

\[
\leq \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}V_{h+1}^v - \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1} + b_h(s, \pi_h^*(s))
\]

\[
\leq \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}V_{h+1}^v - \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1} + b_h(s, \pi_h^*(s))
\]

\[
= \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1} + b_h(s, \pi_h^*(s))
\]

\[
\leq \hat{P}_{h,s,\pi_h^*}^v(s) \leq \hat{V}_{h+1} + 2b_h(s, \pi_h^*(s)),
\]

where (i) holds by applying Lemma 2 (cf. (76)) since \( \hat{V}_{h+1} \) is independent of \( P_{h,s,\pi_h^*}^0(s) \) by construction, and (ii) arises from introducing the notation

\[
\hat{P}_{h,s,\pi_h^*}^v := \arg\min_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1}
\]

and consequently,

\[
\inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}V_{h+1}^v \leq \hat{P}_{h,s,\pi_h^*}^v V_{h+1}^v, \quad \text{and} \quad \inf_{P \in U^r(p_{h,s,\pi_h^*}^0)} \mathcal{P}\hat{V}_{h+1} = \hat{P}_{h,s,\pi_h^*}^v \hat{V}_{h+1}.
\]

To continue, let us introduce some additional notation for convenience. Define a sequence of matrices \( \hat{P}_h^\inf \in \mathbb{R}^{S \times S} \) and vectors \( b_h^* \in \mathbb{R}^S \) for \( h \in [H] \), where their \( s \)-th rows (resp. entries) are given by

\[
[\hat{P}_h^\inf]_{s} = \hat{P}_{h,s,\pi_h^*}^v(s), \quad \text{and} \quad b_h^*(s) = b_h(s, \pi_h^*(s)).
\]
Applying (82) recursively over the time steps \( h, h+1, \cdots, H \) using the above notation gives

\[
0 \leq V^{\ast,\sigma}_h - \hat{V}_h \leq \hat{p}_h^{\text{inf}} (V^{\ast,\sigma}_{h+1} - \hat{V}_{h+1}) + 2b^*_h
\]

\[
\leq \hat{p}_h^{\text{inf}} \hat{p}_{h+1}^{\text{inf}} (V^{\ast,\sigma}_{h+2} - \hat{V}_{h+2}) + 2\hat{p}_h^{\ast} b_{h+1}^* + 2b_h^* \leq \cdots \leq 2 \sum_{i=h}^{H} \left( \prod_{j=h}^{i-1} \hat{p}_j^{\text{inf}} \right) b^*_i,
\]

where we let \( \left( \prod_{j=1}^{i-1} \hat{p}_j^{\text{inf}} \right) = I \) for convenience.

For any \( d^*_h \in D^*_h \) (cf. (75)), taking inner product with (85) leads to

\[
\langle d^*_h, V^{\ast,\sigma}_h - \hat{V}_h \rangle \leq \left( d^*_h, 2 \sum_{i=h}^{H} \left( \prod_{j=h}^{i-1} \hat{p}_j^{\text{inf}} \right) b^*_i \right) = 2 \sum_{i=h}^{H} \langle d^*_i, b^*_i \rangle,
\]

where

\[
d^*_i := \left( d^*_h \right)^T \left( \prod_{j=h}^{i-1} \hat{p}_j^{\text{inf}} \right) \in D^*_i
\]

by the definition of \( D^*_i \) (cf. (75)) for all \( i = h+1, \cdots, H \).

**Step 3: controlling \( \langle d^*_i, b^*_i \rangle \) using concentrability.** Since \( \langle d^*_i, b^*_i \rangle = \sum_{s \in S} d^*_i(s) b^*_i(s) \), we shall divide the discussion in two different cases.

- For \( s \in S \) where \( \max_{P \in U^\ast(P^0)} d^*_s(P)(s, \pi^*_s(s)) = \max_{P \in U^\ast(P^0)} d^*_s(P)(s) = 0 \), it follows from the definition (cf. (75)) that for any \( d^*_i \in D^*_i \), it satisfies that
  \[
d^*_i(s) = 0.
\]

- For \( s \in S \) where \( \max_{P \in U^\ast(P^0)} d^*_s(P)(s, \pi^*_s(s)) = \max_{P \in U^\ast(P^0)} d^*_s(P)(s) > 0 \), by the assumption in (12)

\[
\max_{P \in U^\ast(P^0)} \min \left\{ d^*_s(P)(s, \pi^*_s(s)), \frac{1}{2} \right\} = \max_{P \in U^\ast(P^0)} \min \left\{ d^*_s(P)(s), \frac{1}{2} \right\} \leq C^*_{\text{rob}} < \infty,
\]

it implies that

\[
d^*_s(s, \pi^*_s(s)) > 0 \quad \text{and} \quad (i, s, \pi^*_s(s)) \in C^b.
\]

Lemma 1 tells that with probability at least \( 1 - 8\delta \),

\[
N_i(s, \pi^*_s(s)) \geq K d^b_i(s, \pi^*_s(s)) \geq -5 \sqrt{K d^b_i(s, \pi^*_s(s)) \log \frac{KH}{\delta}} \geq \frac{K d^b_i(s, \pi^*_s(s))}{16} \geq \frac{K \min \left\{ d^*_s(s), \frac{1}{2} \right\}}{16C^*_{\text{rob}}},
\]

where (i) holds due to

\[
K d^b_i(s, \pi^*_s(s)) \geq c_1 \frac{d^b_i(s, \pi^*_s(s)) \log(KHS/\delta)}{d^b_{\text{min}} P^b_{\text{min}}} \geq c_1 \log \frac{K H}{\delta} \geq c_1 \log \frac{K H}{\delta}
\]

for some sufficiently large \( c_1 \), where the first inequality follows from Condition (27), the second inequality follows from

\[
d^b_{\text{min}} = \min_{h, s, a} \left\{ d^b_h(s, a) : d^b_h(s, a) > 0 \right\} \leq d^b_i(s, \pi^*_s(s))
\]
and the last inequality follows from $P_{\operatorname{min}}^b \leq 1$. In addition, (ii) follows from Assumption 1.

With this in place, we observe that the pessimistic penalty (see (21)) obeys

$$b^*_i(s) \leq c_b \frac{H}{\sigma} \sqrt{\frac{\log \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) N_i(s, \pi^*_i(s))}} \leq 4c_b \frac{H}{\sigma} \sqrt{\frac{\log \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) N_i(s, \pi^*_i(s))}} \leq 16c_b \frac{H}{\sigma} \sqrt{\frac{C_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) K \min \{d^*_i(s), \frac{1}{3}\}}},$$

(93)

where (i) holds by applying (77) in view of the fact that $(i, s, \pi^*_i(s)) \in C^b$ by (89), and the last inequality holds by (90).

Combining the results in the above two cases leads to

$$\sum_{s \in S} d^*_i(s) b^*_i(s) \leq \sum_{s \in S} 16 d^*_i(s) c_b \frac{H}{\sigma} \sqrt{\frac{C_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) K \min \{d^*_i(s), \frac{1}{3}\}}} \leq 16c_b \frac{H}{\sigma} \sqrt{\frac{C_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) K \min \{d^*_i(s), \frac{1}{3}\}}} \sum_{s \in S} d^*_i(s) \leq 32c_b \frac{H}{\sigma} \sqrt{\frac{SC_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) K}},$$

(94)

where (i) follows from the Cauchy-Schwarz inequality and the last inequality hold by the trivial fact

$$\sum_{s \in S} \min \{d^*_i(s), \frac{1}{3}\} \leq \sum_{s \in S} d^*_i(s) \left(\frac{1}{d^*_i(s)} + \frac{1}{1/3}\right) = \sum_{s \in S} 1 + \frac{1}{3} \sum_{s \in S} d^*_i(s) \leq 2.$$  

(95)

**Step 4: finishing up the proof.** Then, inserting (94) back into (86) with $h = 1$ shows

$$\left\langle d^*_i, V^*_{i\sigma} - \hat{V}_i \right\rangle \leq 2 \sum_{i=1}^H \left\langle d^*_i, b^*_i \right\rangle \leq 64c_b \frac{H}{\sigma} \sqrt{\frac{SC_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min,i}(s, \pi^*_i(s)) K}} \leq 2c_2 \frac{H^2}{\sigma} \sqrt{\frac{SC_{\operatorname{rob}}^* \log^2 \frac{KHS}{\delta}}{P_{\min}^b}},$$

(96)

where the last inequality holds by plugging in the relation $P_{\min}^b \leq P_{\min,i}(s, \pi^*_i(s))$ for $i = 1, \ldots, H$ by the definition in (23) (see also (74)), and choosing $c_2$ to be large enough. The proof is completed.

**B.2 Proof of Lemma 10**

To begin, we shall introduce the following fact that

$$\forall (h, s, a) \in C^b : \quad N_h(s, a) \geq c_1 \log \frac{KHS}{\delta} \geq \frac{\log \frac{2KHS}{\delta}}{\log(1 - P_{\min,h}(s, a))},$$

(97)

as long as Condition (27) holds. The proof is postponed to Appendix B.2.3. With this in mind, we shall first establish the simpler bound (77) and then move on to show (76).

**B.2.1 Proof of (77)**

To begin, recall that (97) is satisfied for all $(h, s, a) \in C^b$. By Lemma 8 and the union bound, it holds that with probability at least $1 - \delta$ that for all $(h, s, a) \in C^b$:

$$\forall s' \in S : \quad P^b_h(s' | s, a) \geq \frac{P^0_h(s' | s, a)}{e^2} \geq \frac{P^0_h(s' | s, a)}{8e^2 \log \frac{KHS}{\delta}}.$$  

(98)
To characterize the relation between \( P_{\min,h}(s,a) \) and \( \hat{P}_{\min,h}(s,a) \) for any \((h,s,a) \in C^b\), we suppose—without loss of generality—that \( P_{\min,h}(s,a) = P_0^h(s_1 | s,a) \) and \( \hat{P}_{\min,h}(s,a) = \hat{P}_0^h(s_2 | s,a) \) for some \( s_1, s_2 \in S \). Then, it follows that

\[
P_{\min,h}(s,a) = P_0^h(s_1 | s,a) \geq \frac{\hat{P}_0^h(s_1 | s,a)}{e^2} \geq \frac{\hat{P}_{\min,h}(s,a)}{e^2} = \frac{\hat{P}_0^h(s_2 | s,a)}{e^2} \geq \frac{P_{\min,h}(s,a)}{8e^2 \log(\frac{KH}{\delta})},
\]

where (i) and (ii) follow from (98).

**B.2.2 Proof of (76)**

The main goal of (76) is to control the gap between robust Bellman operations based on the nominal transition kernel \( P_{h,s,a}^0 \) and the estimated kernel \( \hat{P}_{h,s,a}^0 \) by the constructed penalty term. Towards this, first consider \((h,s,a) \notin C^b\), which corresponds to the state-action pairs \((s,a)\) that haven’t been visited at step \( h \) by the behavior policy. In other words, \( N_h(s,a) = 0 \). In this case, (76) can be easily verified that

\[
\inf_{P \in U^N(P_{h,s,a}^0)} \| PV - \inf_{P \in U^N(P_{h,s,a}^0)} PV \|_{\infty} \leq \| V \|_{\infty} \leq H \equiv b_h(s,a),
\]

where (i) follows from the fact \( \hat{P}_{h,s,a}^0 = 0 \) when \( N_h(s,a) = 0 \) (see (15)), (ii) arises from the assumption \( \| V \|_{\infty} \leq H \), and (iii) holds by the definition of \( b_h(s,a) \) in (21). Therefore, the remainder of the proof will focus on verifying (76) for \((h,s,a) \in C^b\). Rewriting the term of interest via duality (cf. Lemma 4) yields

\[
\inf_{P \in U^N(P_{h,s,a}^0)} \| PV - \inf_{P \in U^N(P_{h,s,a}^0)} PV \|_{\infty} \leq \inf_{P \in U^N(P_{h,s,a}^0)} \| PV \|_{\infty} - \inf_{P \in U^N(P_{h,s,a}^0)} \| PV \|_{\infty} \leq \| V \|_{\infty} \leq H \equiv b_h(s,a),
\]

Denoting

\[
\lambda_{h,s,a} := \arg\max_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( \frac{-V}{\lambda} \right) \right) - \lambda \right\},
\]

\[
\lambda_h^* := \arg\max_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( \frac{-V}{\lambda} \right) \right) - \lambda \right\},
\]

Lemma 5 (cf. (62)) then gives that

\[
\lambda_{h,s,a} \in \left[ 0, \frac{H}{\sigma} \right], \quad \lambda_h^* \in \left[ 0, \frac{H}{\sigma} \right],
\]

due to \( \| V \|_{\infty} \leq H \). We shall control (100) in three different cases separately: (a) \( \lambda_{h,s,a}^* = 0 \) and \( \lambda_{h,s,a} = 0 \); (b) \( \lambda_{h,s,a}^* > 0 \) and \( \lambda_{h,s,a} = 0 \) or \( \lambda_{h,s,a}^* = 0 \) and \( \lambda_{h,s,a}^* > 0 \); and (c) \( \lambda_{h,s,a}^* \neq 0 \) or \( \lambda_{h,s,a}^* \neq 0 \).

**Case (a): \( \lambda_{h,s,a}^* = 0 \) and \( \lambda_{h,s,a} = 0 \).** Applying Lemma 5 and Lemma 6 to (100) gives that, with probability at least \( 1 - \frac{\delta}{KH} \),

\[
\inf_{P \in U^N(P_{h,s,a}^0)} \| PV - \inf_{P \in U^N(P_{h,s,a}^0)} PV \|_{\infty} \leq \| \text{essinf}_{s \sim \hat{P}_{h,s,a}^0} V(s) - \text{essinf}_{s \sim P_{h,s,a}^0} V(s) \|_{\infty}
\]

\[
\leq \| \text{essinf}_{s \sim \hat{P}_{h,s,a}^0} V(s) - \text{essinf}_{s \sim P_{h,s,a}^0} V(s) \|_{\infty} \leq b_h(s,a),
\]

where (i) holds by Lemma 5 (cf. (64)) and (ii) arises from Lemma 6 (cf. (65)) given (97).
Case (b): $\lambda_{h,s,a}^* > 0$ and $\hat{\lambda}_{h,s,a}^* = 0$ or $\lambda_{h,s,a}^* = 0$ and $\hat{\lambda}_{h,s,a}^* > 0$. Towards this, note that two trivial facts are implied by the definition (101):

$$\sup_{\lambda \geq 0} \left\{ -\lambda \log \left( P_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} \geq -\hat{\lambda}_{h,s,a}^* \log \left( P_{h,s,a}^0 \cdot \exp \left( -\frac{V}{\hat{\lambda}_{h,s,a}^*} \right) \right) - \hat{\lambda}_{h,s,a}^* \sigma, \quad (104a)$$

$$\sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} \geq -\hat{\lambda}_{h,s,a}^* \log \left( \hat{P}_{h,s,a}^0 \cdot \exp \left( -\frac{V}{\hat{\lambda}_{h,s,a}^*} \right) \right) - \hat{\lambda}_{h,s,a}^* \sigma. \quad (104b)$$

To continue, first, we consider a subcase when $\lambda_{h,s,a}^* = 0$ and $\hat{\lambda}_{h,s,a}^* > 0$. With probability at least $1 - \frac{\delta}{K H}$, it follows from Lemma 5 (cf. (64)) and Lemma 6 (cf. (65)) that

$$\sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} \geq \lim_{\lambda \to 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} \geq \text{essinf}_{s \sim \hat{P}_{h,s,a}^0} V(s) = \text{essinf}_{s \sim \hat{P}_{h,s,a}^0} V(s)$$

$$= \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( P_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\}, \quad (105)$$

leading to

$$\left| \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \hat{P}_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} - \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( P_{h,s,a}^0 \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\} \right| \leq \hat{\lambda}_{h,s,a}^* \left| \log \left( P_{h,s,a}^0 \cdot \exp \left( -\frac{V}{\hat{\lambda}_{h,s,a}^*} \right) \right) - \log \left( \hat{P}_{h,s,a}^0 \cdot \exp \left( -\frac{V}{\hat{\lambda}_{h,s,a}^*} \right) \right) \right|, \quad (106)$$

where (i) follows from the definition of $\hat{\lambda}_{h,s,a}^*$ in (101) and the fact in (104a).

We pause to claim that with probability at least $1 - \delta$, the following bound holds

$$\forall (h,s,a) \in C^b, V \in \mathbb{R}^S : \left| \frac{\hat{P}_{h,s,a}^0 - P_{h,s,a}^0}{P_{h,s,a}^0} \cdot \exp \left( -\frac{V}{\lambda} \right) \right| \leq \sqrt{\frac{\log(KH_s^2)}{\lambda}} \leq \frac{1}{2} \quad (107)$$

The proof is postponed to Appendix B.2.4. With (107) in place, we can further bound (106) (which is plugged into (100)) as

$$\left| \inf_{P \in U^c(\hat{P}_{h,s,a}^0)} PV - \inf_{P \in U^c(P_{h,s,a}^0)} PV \right| \leq \hat{\lambda}_{h,s,a}^* \log \left( 1 + \frac{(\hat{P}_{h,s,a}^0 - P_{h,s,a}^0) \cdot \exp \left( -\frac{V}{\lambda} \right)}{P_{h,s,a}^0 \cdot \exp \left( -\frac{V}{\lambda} \right)} \right) \leq 2\hat{\lambda}_{h,s,a}^*$$

$$\leq \frac{2H}{\sigma} \sqrt{\frac{\log(KH_s^2)}{\lambda}}, \quad (i)$$

$$\leq \frac{2H \log(KH_s^2)}{\sigma} \sqrt{\frac{1}{\lambda}} \leq \frac{c_0 H \log(KH_s^2)}{\sigma P_{\min,h}(s,a) N_h(s,a)} \leq \frac{c_0 H \log(KH_s^2)}{\sigma P_{\min,h}(s,a) N_h(s,a)}, \quad (108)$$

where (i) follows from $\log(1 + x) \leq 2|x|$ for any $|x| \leq \frac{1}{2}$ in view of (107), (ii) follows from (102) as well as (107), and the last line follows from (77) and choosing $c_0$ to be sufficiently large.
Moreover, note that it can be easily verified that
\[
\left| \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V - \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V \right| \leq H
\]
due to the assumption \( \|V\|_\infty \leq H \). Plugging in the definition of \( b_h(s, a) \) in (21), combined with the above bounds, we have that with probability at least \( 1 - \delta \),
\[
\left| \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V - \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V \right| \leq \min \left\{ c_h \frac{H}{\sigma} \sqrt{\frac{\log(KHS/\delta)}{N_h(s,a) P_{\min,h}(s,a)}}, \, H \right\} =: b_h(s, a). \tag{109}
\]

The other subcase when \( \lambda^*_{h,s,a} > 0 \) and \( \hat{\lambda}^*_{h,s,a} = 0 \) follows similarly from the bound
\[
\left| \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \frac{P_{h,s,a}^0}{\lambda} \right) \right\} \right| \leq \lambda_{h,s,a} \left| \log \left( \frac{P_{h,s,a}^0}{\lambda_{h,s,a}} \right) \right| - \log \left( \frac{P_{h,s,a}^0}{\lambda_{h,s,a}} \right), \tag{110}
\]
and therefore, will be omitted for simplicity.

**Case (c): \( \lambda^*_{h,s,a} > 0 \) and \( \hat{\lambda}^*_{h,s,a} > 0 \).** It follows that
\[
\left| \sup_{\lambda \geq 0} \left\{ -\lambda \log \left( \frac{P_{h,s,a}^0}{\lambda} \right) \right\} \right| \leq \max_{\lambda \in \{\lambda^*_{h,s,a}, \hat{\lambda}^*_{h,s,a}, \lambda_{h,s,a}\}} \left| \log \left( \frac{P_{h,s,a}^0}{\lambda_{h,s,a}} \right) \right| - \log \left( \frac{P_{h,s,a}^0}{\lambda_{h,s,a}} \right), \tag{111}
\]
where (i) can be verified by applying the facts in (104). Hence, the above term (111) can be controlled again in a similar manner as (106); we omit the details for simplicity.

**Summing up.** Combining the previous results in different cases by the union bound, with probability at least \( 1 - 10\delta \), it is satisfied that for all \( (h, s, a) \in \mathcal{C}^{b} \):
\[
\left| \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V - \inf_{P \in U^*(P_{h,s,a}^0)} \mathcal{P}V \right| \leq b_h(s, a),
\]
which concludes the proof.

**B.2.3 Proof of (97)**

Observe that for all \( (h, s, a) \in \mathcal{C}^{b} \):
\[
Kd_h^b(s, a) \geq \frac{c_1 \log(KHS/\delta)}{\frac{P_{\min}^b}{P_{\min}^b}} \geq \frac{c_1 \log(KHS/\delta)}{P_{\min,h}(s,a)}, \tag{112}
\]
where (i) follows from Condition (27), (ii) follows from the definition that \( d_{\min}^b \leq d_h^b(s, a) \) for \( (h, s, a) \in \mathcal{C}^{b} \), and (iii) comes from (74).
Lemma 1 then tells that with probability at least \(1 - 8\delta\),

\[
N_h(s, a) \geq \frac{Kd_h^b(s, a)}{8} - 5\sqrt{Kd_h^b(s, a) \log \frac{KH}{\delta}} \geq \frac{Kd_h^b(s, a)}{16} \geq \frac{c_1 \log KH}{16P_{\min, h}(s, a)},
\]

where the second line follows from the above relation as long as \(c_1\) is sufficiently large. The last inequality of (97) then follows from

\[
c_1 \log \frac{KHS}{\delta} \geq - \frac{\log 2KHS}{\log(1 - P_{\min, h}(s, a))},
\]

since \(x \leq -\log(1 - x)\) for all \(x \in [0, 1]\).

### B.2.4 Proof of (107)

Denoting

\[
supp(P^0_{h,s,a}) := \{ s' \in S : P^0_h(s' | s, a) > 0 \}
\]

as the support of \(P^0_{h,s,a}\), we observe that

\[
\frac{\left| \left( \hat{P}^0_{h,s,a} - P^0_{h,s,a} \right) \cdot \exp \left( -\frac{V(s', a)}{\lambda} \right) \right|}{P^0_{h,s,a} \cdot \exp \left( -\frac{V(s', a)}{\lambda} \right)} \leq \frac{\sum_{s' \in supp(P^0_{h,s,a})} \left| \hat{P}^0_h(s' | s, a) - P^0_h(s' | s, a) \right| \exp \left( -\frac{V(s', a)}{\lambda} \right)}{\sum_{s' \in supp(P^0_{h,s,a})} P^0_h(s' | s, a) \exp \left( -\frac{V(s', a)}{\lambda} \right)} \leq \max_{s' \in supp(P^0_{h,s,a})} \frac{\left| \hat{P}^0_h(s' | s, a) - P^0_h(s' | s, a) \right|}{P^0_h(s' | s, a)},
\]

where the second line follows from \(\sum_i a_i = \sum_i b_i \leq (\max_i b_i) \sum_i b_i\) for any positive sequences \(\{a_i, b_i\}_i\) obeying \(a_i, b_i > 0\).

To continue, note that for any \((h, s, a) \in C^b\) and \(s' \in supp(P^0_{h,s,a})\), \(N_h(s, a) \hat{P}^0_h(s' | s, a)\) follows the binomial distribution \(\text{Binomial}(N_h(s, a), P^0_h(s' | s, a))\). Thus, applying Lemma 7 with \(t = \sqrt{\frac{\log(\frac{KHS}{\delta})}{c_1N_h(s, a)P^0_h(s' | s, a)}}\) yields

\[
P \left( \left| \hat{P}^0_h(s' | s, a) - P^0_h(s' | s, a) \right| \geq P^0_h(s' | s, a) t \right) \leq \exp \left( -c_1N_h(s, a)P^0_h(s' | s, a) t^2 \right) \leq \frac{\delta}{KHS},
\]

as soon as \(t \leq \frac{1}{2}\), which can be verified by the fact (97) and \(P_{\min, h}(s, a) \leq P^0_h(s' | s, a)\) (cf. (73)), namely,

\[
N_h(s, a) \geq \frac{c_1 \log \frac{KHS}{\delta}}{16P_{\min, h}(s, a)} \geq \frac{\log \left( \frac{KHS}{\delta} \right)}{4c_1P_{\min, h}(s, a)} \geq \frac{\log \left( \frac{KHS}{\delta} \right)}{4c_1P_{\min, h}(s, a)}
\]

as long as \(c_1\) is sufficiently large.

Applying (116) and taking the union bound over \(s \in supp(P^0_{h,s,a})\) lead to that with probability at least \(1 - \frac{\delta}{KHS}\),

\[
\max_{s' \in supp(P^0_{h,s,a})} \left| \hat{P}^0_h(s' | s, a) - P^0_h(s' | s, a) \right| \leq \max_{s' \in supp(P^0_{h,s,a})} \frac{P^0_h(s' | s, a) \sqrt{\log \frac{KHS}{\delta}}}{c_1N_h(s, a)P_{\min, h}(s, a)} \leq \frac{1}{2},
\]

where the last line uses again (117). Plugging this back into (115) and applying the union bound over \((h, s, a) \in C^b\) then completes the proof.
B.3 Proof of Theorem 2

The proof of Theorem 2 is inspired by the construction in Li et al. (2022) for standard MDPs, but is considerably more involved to handle the uncertainty set unique in robust MDPs. We shall first construct some hard instances and then characterize the sample complexity requirements over these instances.

B.3.1 Construction of hard problem instances

Construction of a collection of hard MDPs. Let us introduce two MDPs

\[ \mathcal{M}_\phi = \left( \mathcal{S}, \mathcal{A}, P^\phi = \{ P^\phi_h \}_{h=1}^{H}, \{ r_h \}_{h=1}^{H}, H \right) \mid \phi = \{0, 1\} \],

where the state space is \( \mathcal{S} = \{0, 1, \ldots, S-1\} \), and the action space is \( \mathcal{A} = \{0, 1\} \). The transition kernel \( P^\phi \) of the constructed MDP \( \mathcal{M}_\phi \) is defined as

\[
P^\phi(s' \mid s, a) = \begin{cases} 
    p \mathbb{I}(s' = 0) + (1 - p) \mathbb{I}(s' = 1) & \text{if } (s, a) = (0, \phi) \\
    q \mathbb{I}(s' = 0) + (1 - q) \mathbb{I}(s' = 1) & \text{if } (s, a) = (0, 1 - \phi) \\
    \mathbb{I}(s' = 1) & \text{if } s = 1 \\
    q \mathbb{I}(s' = s) + (1 - q) \mathbb{I}(s' = 1) & \text{if } s > 1
\end{cases}
\]

and

\[
P^\phi_h(s' \mid s, a) = \mathbb{I}(s' = s), \quad \forall (h, s, a) \in \{2, \ldots, H\} \times \mathcal{S} \times \mathcal{A}.
\]

In words, except at step \( h = 1 \), the MDP always stays in the same state. Additionally, the MDP will always stay in the state subset \( \{0, 1\} \) if the initial distribution is supported only on \( \{0, 1\} \), in view of (119). Here, \( p \) and \( q \) are set to be

\[
p = 1 - \alpha \quad \text{and} \quad q = 1 - \alpha - \Delta
\]

for some \( H \geq 2e^8, \alpha \) and \( \Delta \) obeying

\[
0 < \alpha \leq \frac{1}{H} \leq \frac{1}{2e^8} \quad \text{and} \quad \Delta \leq \frac{\alpha}{2} \leq \frac{1}{2H} \leq \frac{1}{4e^8},
\]

where \( \beta \) is set as

\[
\beta := \frac{\log \frac{1}{\alpha + \Delta}}{2} \geq \frac{\log(2H/3)}{2} \geq 4.
\]

The assumption (121) immediately indicates the facts

\[
1 > p > q \geq \frac{1}{2}.
\]

Moreover, for any \((h, s, a) \in [H] \times \mathcal{S} \times \mathcal{A}\), the reward function is defined as

\[
r_h(s, a) = \begin{cases} 
    1 & \text{if } s = 0 \\
    0 & \text{otherwise}
\end{cases}
\]

Construction of the history/batch dataset. In the nominal environment \( \mathcal{M}_\phi \), a batch dataset is generated consisting of \( K \) independent sample trajectories each of length \( H \), where each trajectory is generated according to (10), based on the following initial state distribution \( \rho^b \) and behavior policy \( \pi_h^b = \{ \pi_h^b \}_{h=1}^{H} \):

\[
\rho^b(s) = \mu(s) \quad \text{and} \quad \pi^b_h(a \mid s) = \frac{1}{2}, \quad \forall (s, a, h) \in \mathcal{S} \times \mathcal{A} \times [H].
\]

Here, \( \mu(s) \) is defined as the following state distribution supported on the state subset \( \{0, 1\} \):

\[
\mu(s) = \frac{1}{CS} \mathbb{I}(s = 0) + \left(1 - \frac{1}{CS}\right) \mathbb{I}(s = 1),
\]

32
where \( \mathbb{1}(\cdot) \) is the indicator function, and \( C > 0 \) is some constant that will determine the concentrability coefficient \( C_{\text{rob}}^* \) (as we shall detail momentarily) and obeys
\[
\frac{1}{CS} \leq \frac{1}{4}.
\] (127)

As it turns out, for any MDP \( \mathcal{M}_\phi \), the occupancy distributions of the above batch dataset are the same (due to symmetry) and admit the following simple characterization:
\[
d_b, P_\phi (0, a) = \frac{1}{2} \mu(0), \quad \forall a \in \mathcal{A},
\] (128a)
\[
\frac{\mu(s)}{2} \leq d_h, P_\phi (s) \leq 2\mu(s), \quad \frac{\mu(s)}{4} \leq d_h, P_\phi (s, a) \leq \mu(s), \quad \forall (s, a, h) \in \mathcal{S} \times \mathcal{A} \times [H].
\] (128b)

In addition, we choose the following initial state distribution
\[
\rho(s) = \begin{cases} 1, & \text{if } s = 0 \\ 0, & \text{if } s > 0 \end{cases}.
\] (129)

The proof of the claim (128) is postponed to Appendix B.3.3.

**Uncertainty set of the transition kernels.** Denote the transition kernel vector as
\[
P_{h, s, a}^\phi := P_h^\phi (\cdot \mid s, a) \in [0, 1]^{1 \times S}.
\] (130)

For any \( (s, a, h) \in \mathcal{S} \times \mathcal{A} \times [H] \), the perturbation of the transition kernels in \( \mathcal{M}_\phi \) is restricted to the following uncertainty set
\[
\mathcal{U}^\sigma (P^\phi) := \otimes \mathcal{U}^\sigma \left( P_{h, s, a}^\phi \right), \quad \mathcal{U}^\sigma (P_{h, s, a}^\phi) := \left\{ P_{h, s, a} \in \Delta(S) : \KL(\mu_h(s, a) \parallel P_{h, s, a}^\phi) \leq \sigma \right\},
\] (131)

where the radius of the uncertainty set \( \sigma \) obeys
\[
\left(1 - \frac{3}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right) \leq \sigma \leq \left(1 - \frac{2}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right).
\] (132)

Before continuing, we shall introduce some notation for convenience. For any \( P_h^\phi (\cdot \mid s, a) \) in (119), we define the limit of the perturbed kernel transiting to the next state \( s' \) from the current state-action pair \( (s, a) \) by
\[
P_h^\phi (s' \mid s, a) := \inf_{P_{h, s, a} \in \mathcal{U}^\sigma (P_{h, s, a}^\phi)} P_h(s' \mid s, a),
\] (133)

and in particular, denote
\[
p := P_{1}^\phi (0 \mid 0, \phi), \quad q = P_{1}^\phi (0 \mid 0, 1 - \phi).
\] (134)

Armed with the above definitions, we introduce the following lemma which implies some useful properties of the uncertainty set.

**Lemma 11.** When \( \beta \) satisfies (122) and the uncertainty level \( \sigma \) satisfies (132), the perturbed transition kernels obey
\[
p \geq q \geq \frac{1}{\beta}.
\] (135)

**Proof.** See Appendix B.3.4. \( \square \)
Value functions and optimal policies. We take a moment to derive the corresponding value functions and identify the optimal policies. With some abuse of notation, for any MDP $\mathcal{M}_\phi$, we denote $\pi^\ast,\phi = \{\pi^\ast_h,\phi\}_{h=1}^H$ as the optimal policy, and let $V_{\pi^\ast,\sigma,\phi}$ (resp. $V_{\pi^\ast,\sigma,\phi}$) represent the robust value function of policy $\pi^\ast$ (resp. $\pi^\ast,\phi$) at step $h$ with uncertainty radius $\sigma$. Armed with these notation, we introduce the following lemma which collects the properties concerning the value functions and optimal policies.

**Lemma 12.** For any $\phi = \{0, 1\}$ and any policy $\pi$, defining

$$z^\pi_\phi := p\pi_1(\phi | 0) + q\pi_1(1 - \phi | 0), \quad (136)$$

it holds that

$$V_{1^\pi,\sigma,\phi}(0) = 1 + z^\pi_\phi(H - 1). \quad (137)$$

In addition, the optimal policies and the optimal value functions obey

$$V_{1^\star,\sigma,\phi}(0) = 1 + p(H - 1), \quad (138a)$$
$$\forall h \in [H] \setminus \{1\} : \quad V_{h^\star,\sigma,\phi}(0) = H - h + 1, \quad (138b)$$
$$\forall h \in [H] : \quad \pi^\star_h(\phi | 0) = 1, \quad \pi^\star_h(\phi | 1) = 1, \quad V_{h^\star,\sigma,\phi}(1) = 0. \quad (138c)$$

The robust single-policy clipped concentrability coefficient $C_{\text{rob}}^\ast$ obeys

$$2C \leq C_{\text{rob}}^\ast \leq 4C. \quad (139)$$

**Proof.** See Appendix B.3.5. \[\Box\]

In view of Lemma 12, we note that the smallest positive state transition probability of the optimal policy $\pi^\ast$ under any MDP $\mathcal{M}_\phi$ with $\phi \in \{0, 1\}$ thus can be given by

$$P_{\min}^\ast := \min_{h,s,s'} \left\{ P^\phi_h(s'|s,\pi^\ast_h(s)) : P^\phi_h(s'|s,\pi^\ast_h(s)) > 0 \right\} = P^\phi_1(1|0,1-\phi) = 1 - p, \quad (140)$$

which obeys

$$\alpha = P_{\min}^\ast \in \left(0, 1/H\right]$$

according to (128) and (129).

**B.3.2 Establishing the minimax lower bound**

We are now ready to establish the sample complexity lower bound. With the choice of the initial distribution $\rho$ in (129), for any policy estimator $\hat{\pi}$ computed based on the batch dataset, we plan to control the quantity

$$\langle \rho, V_{1^\star,\sigma,\phi} - V_{1^\hat{\pi},\sigma,\phi} \rangle = V_{1^\star,\sigma,\phi}(0) - V_{1^\hat{\pi},\sigma,\phi}(0).$$

**Step 1: converting the goal to estimate $\phi$.** We make the following claim which shall be verified in Appendix B.3.6: given $\varepsilon \leq \frac{H}{384e^6 \log(\frac{1}{\alpha})} \leq \frac{H}{384e^6 \log(\frac{1}{\alpha + \Delta})}$, choosing

$$\Delta = \frac{128e^6(1-q)\varepsilon}{H} \leq \frac{128e^6(\alpha + \Delta)\varepsilon}{H} \leq \frac{128e^6(\alpha + \Delta)\varepsilon \log\left(\frac{1}{\alpha + \Delta}\right)}{H} \leq \frac{\alpha}{2}, \quad (141)$$

which satisfies (121) with the aid of (132) and (120), it holds that for any policy $\hat{\pi}$,

$$\langle \rho, V_{1^\star,\sigma,\phi} - V_{1^\hat{\pi},\sigma,\phi} \rangle \geq 2\varepsilon(1 - \hat{\pi}(\phi | 0)). \quad (142)$$

Armed with this relation between the policy $\hat{\pi}$ and its sub-optimality gap, we are positioned to construct an estimate of $\phi$. We denote $P_{\phi}$ as the probability distribution when the MDP is $\mathcal{M}_\phi$, for any $\phi \in \{0, 1\}$.
Suppose for the moment that a policy estimate \( \hat{\pi} \) achieves
\[
P_{\phi} \left\{ \langle \rho, V^*_1, \sigma, \phi \rangle - V^*_1, \sigma, \phi \rangle \leq \varepsilon \right\} \geq \frac{7}{8},
\]
then in view of (142), we necessarily have \( \hat{\pi}_1(\phi | 0) \geq \frac{1}{2} \) with probability at least \( \frac{7}{8} \). With this in mind, we are motivated to construct the following estimate \( \hat{\phi} \) for \( \phi \in \{0,1\} \):
\[
\hat{\phi} = \arg \max_{a \in \{0,1\}} \hat{\pi}_1(a | 0),
\]
which obeys
\[
P_{\phi} \{ \hat{\phi} = \phi \} \geq P_{\phi} \{ \hat{\pi}_1(\phi | 0) > 1/2 \} \geq \frac{7}{8}.
\]
In what follows, we would like to show (145) cannot happen without enough samples, which would in turn contradict (142).

**Step 2: probability of error in testing two hypotheses.** Armed with the above preparation, we shall focus on differentiating the two hypotheses \( \phi \in \{0,1\} \). Towards this, consider the minimax probability of error defined as follows:
\[
p_e := \inf_{\psi} \max_{a \in \{0,1\}} \{ P_0(\psi \neq 0), P_1(\psi \neq 1) \},
\]
where the infimum is taken over all possible tests \( \psi \) constructed from the batch dataset.

Let \( \mu^{b,\phi} \) (resp. \( \mu^{b,\phi}(s_h) \)) be the distribution of a sample trajectory \( \{s_h, a_h\}_{h=1}^{H} \) (resp. a sample \( (a_h, s_{h+1}) \)) conditional on \( s_h \) for the MDP \( M_\phi \). Following standard results from Tsybakov and Zaiats (2009, Theorem 2.2) and the additivity of the KL divergence (cf. Tsybakov and Zaiats (2009, Page 85)), we obtain
\[
p_e \geq \frac{1}{4} \exp \left\{ -\frac{1}{2} KL(\mu^{b,0} \parallel \mu^{b,1}) \right\}
\]
\[
\geq \frac{1}{4} \exp \left\{ -\frac{1}{2} KL(P_0(\cdot | 0, 0) \parallel P_1(\cdot | 0, 0)) + KL(P_0(\cdot | 0, 1) \parallel P_1(\cdot | 0, 1)) \right\},
\]
where we also use the independence of the \( K \) trajectories in the batch dataset in the first line. Here, the second line arises from the chain rule of the KL divergence (Duchi, 2018, Lemma 5.2.8) and the Markov property of the sample trajectories (recall that \( d_{h,p_0} = d_{h,p_1}^{b,\phi} \)) according to
\[
KL(\mu^{b,0} \parallel \mu^{b,1}) = \sum_{h=1}^{H} \mathbb{E}_{s_h \sim d_h^{b,\rho_0}} \left[ KL(\mu_h^{b,0}(s_h) \parallel \mu_h^{b,1}(s_h)) \right]
\]
\[
= \sum_{a \in \{0,1\}} d_{1}^{b,\rho_0}(0, a) KL(P_0^0(\cdot | 0, 0) \parallel P_1^0(\cdot | 0, a))
\]
\[
= \frac{1}{2} \mu(0) \sum_{a \in \{0,1\}} KL(P_0^0(\cdot | 0, a) \parallel P_1^0(\cdot | 0, 0)),
\]
where the penultimate equality holds by the fact that \( P_0^0(\cdot | s, a) \) and \( P_1^0(\cdot | s, a) \) only differ when \( h = 1 \) and \( s = 0 \), and the last equality follows from (128).

It remains to control the KL divergence terms in (147). Given \( p \geq q \geq 1/2 \) (cf. (123)), applying Lemma 9 (cf. (70)) yields
\[
KL(P_0^0(\cdot | 0, 0) \parallel P_1^0(\cdot | 0, 0)) \leq KL(p \parallel q) \leq \frac{(p-q)^2}{(1-p)p} \frac{\Delta^2}{p(1-p)} = \frac{128^2 \epsilon^4(1-q)^2 \epsilon^2}{H^2 p(1-p)}.
\]
(iii) \[ \leq \frac{c_1 \sigma^2 P_{\min}^* \varepsilon^2}{H^2}, \] (148)

where (i) follows from the definition (120), (ii) holds by plugging in the expression of \( \Delta \) in (141), (iii) arises from \( 1 - q \leq 2(1 - p) = 2P_{\min}^* \) (see (121) and (140)), \( p > 1/2 \), as long as \( c_1 \) is a large enough constant. It can be shown that \( \text{KL}(P_1 \parallel P_0) \) can be upper bounded in the same way. Substituting (148) back into (147) demonstrates that: if the sample size is chosen as

\[ KH \leq \frac{H^3 S C_{\text{rob}}^* \log 2}{4c_1 P_{\min}^* \sigma^2 \varepsilon^2}, \] (149)

then one necessarily has

\[ p_0 \geq \frac{1}{4} \exp \left\{ - \frac{1}{2} K \mu(0) \cdot \frac{2c_1 \sigma^2 P_{\min}^* \varepsilon^2}{H^2} \right\} \]

\[ \geq \frac{1}{4} \exp \left\{ - \frac{K c_1 \sigma^2 P_{\min}^* \varepsilon^2}{S C_{\text{rob}}^* H^2} \right\} \geq \frac{1}{8}, \] (150)

where (i) follows from (126) and (ii) holds by (139).

**Step 3: putting things together.** Finally, suppose that there exists an estimator \( \hat{\pi} \) such that

\[ \mathbb{P}_0\{\langle \rho, V_1^{*, \sigma, 0} - V_1^{\hat{\pi}, \sigma, 0} \rangle > \varepsilon\} < \frac{1}{8} \quad \text{and} \quad \mathbb{P}_1\{\langle \rho, V_1^{*, \sigma, 1} - V_1^{\hat{\pi}, \sigma, 1} \rangle > \varepsilon\} < \frac{1}{8}, \]

Then Step 1 tells us that the estimator \( \hat{\phi} \) defined in (144) must satisfy

\[ \mathbb{P}_0(\hat{\phi} \neq 0) < \frac{1}{8} \quad \text{and} \quad \mathbb{P}_1(\hat{\phi} \neq 1) < \frac{1}{8}, \]

which cannot happen under the sample size condition (149) to avoid contradiction with (150). The proof is thus finished.

**B.3.3 Proof of (128)**

With the initial state distribution and behavior policy defined in (125), we have for any MDP \( M_\phi \) with \( \phi \in \{0, 1\}, \)

\[ d_{b_1}^{\phi, P_0}(s) = \rho^b(s) = \mu(s), \]

which leads to

\[ \forall a \in A : d_{b_1}^{\phi, P_0}(0, a) = \frac{1}{2} \mu(0). \] (151)

In view of (119a), the state occupancy distribution at step \( h = 2 \) obeys

\[ d_{2, b_1}^{\phi, P_0}(0) = \mathbb{P}\left\{ s_2 = 0 \mid s_1 \sim d_{1, b_1}^{\phi, P_0} ; \pi^b \right\} = \mu(0) \left[ \pi_1^b(\phi \mid 0)(p + \pi_1^b(1 - \phi \mid 0)q) \right] = \frac{(p + q)\mu(0)}{2}, \]

and

\[ d_{2, b_1}^{\phi, P_0}(1) = \mathbb{P}\left\{ s_2 = 1 \mid s_1 \sim d_{1, b_1}^{\phi, P_0} ; \pi^b \right\} \]

\[ = \mu(0) \left[ \pi_1^b(\phi \mid 0)(1 - p) + \pi_1^b(1 - \phi \mid 0)(1 - q) \right] + \mu(1) = \mu(1) + \frac{(2 - p - q)\mu(0)}{2}. \]

With the above result in mind and recalling the assumption in (123), we arrive at

\[ \frac{\mu(0)}{2} \leq d_{2, b_1}^{\phi, P_0}(0) \leq \mu(0), \quad \mu(1) \leq d_{2, b_1}^{\phi, P_0}(1) \leq 2\mu(1), \] (152)
where (i) holds by applying (123) and (127) (which implies $\mu(0) \leq \mu(1)$ by the assumption in (127))

$$d_2^{b, P^\phi}(1) = \mu(1) + \frac{(2 - p - q)\mu(0)}{2} \leq \mu(1) + \mu(0) \leq 2\mu(1).$$

Finally, from the definitions of $P_h^\phi(\cdot \mid s, a)$ in (119b) and the Markov property, we arrive at for any $(h, s) \in [H] \times S$,

$$\frac{\mu(s)}{2} \leq d_h^{b, P^\phi}(s) \leq 2\mu(s),$$

which directly leads to

$$\frac{\mu(s)}{4} \leq d_h^{b, P^\phi}(s, a) = \pi_1^b(a \mid s) d_h^{b, P^\phi}(s) \leq \mu(s).$$

### B.3.4 Proof of Lemma 11

Note that $p \geq q$ can be easily verified since $p > q$, which indicates that the first assertion is true. So we will focus on the second assertion in (135). Towards this, invoking the definition in (69), let $\sigma'$ be the KL divergence from $\text{Ber}(\frac{2}{3})$ to $\text{Ber}(q)$, defined as follows

$$\sigma' := \text{KL}(\text{Ber} \left( \frac{1}{\beta} \right) \parallel \text{Ber}(q)) = \frac{1}{\beta} \log \frac{1}{q} + \left(1 - \frac{1}{\beta}\right) \log \left( \frac{1 - \frac{1}{\beta}}{1 - q} \right)$$

$$= \left(\frac{1}{\beta}\right) \log \left( \frac{1}{\beta}\right) - \left(\frac{1}{\beta}\right) \log (q) + \left(1 - \frac{1}{\beta}\right) \log \left( \frac{1}{\alpha + \Delta} \right) + \left(1 - \frac{1}{\beta}\right) \log \left( \frac{1 - \frac{1}{\beta}}{\beta}\right),$$

where the second line uses the definition of $q$ in (120). We claim that $\sigma'$ satisfies the following relation with $\sigma$, which will be proven at the end of this proof:

$$\left(1 - \frac{3}{\beta}\right) \log \left( \frac{1}{\alpha + \Delta} \right) \leq \sigma \leq \left(1 - \frac{2}{\beta}\right) \log \left( \frac{1}{\alpha + \Delta} \right) \leq \sigma' \leq \left(1 - \frac{1}{\beta}\right) \log \left( \frac{1}{\alpha + \Delta} \right).$$

Recalling the definition of the transition kernel in (119a)

$$P_1^\phi(0 \mid 0, 1 - \phi) = q, \quad P_1^\phi(1 \mid 0, 1 - \phi) = 1 - q, \quad P_1^\phi(s \mid 0, 1 - \phi) = 0, \quad \forall s \in S \setminus \{0, 1\},$$

the uncertainty set of the transition kernel with radius $\sigma$ is thus given as

$$U^\sigma(P^\phi_{1,0,1-\phi}) = \{P_{1,0,1-\phi} \in \Delta(S) : P(0 \mid 0, 1 - \phi) = q', P(1 \mid 0, 1 - \phi) = 1 - q', \text{KL}(\text{Ber}(q') \parallel \text{Ber}(q)) \leq \sigma\}.$$

Recalling the definition of $q$ in (134), we can bound

$$q = \inf_{P_{1,0,1-\phi} \in U^\sigma(P^\phi_{1,0,1-\phi})} P(0 \mid 0, 1 - \phi) \quad \text{and} \quad \inf_{q' : \text{KL}(\text{Ber}(q') \parallel \text{Ber}(q)) \leq \sigma} q' \quad \text{by (i)} \quad \geq \quad q' = \frac{1}{\beta},$$

where (i) holds by $\sigma \leq \sigma'$ (cf. (156)) and the last equality follows from applying Lemma 9 (cf. (71)) and (155) to arrive at

$$\forall 0 \leq q' < \frac{1}{\beta} : \quad \text{KL}(\text{Ber}(q') \parallel \text{Ber}(q)) > \text{KL} \left( \text{Ber} \left( \frac{1}{\beta} \right) \parallel \text{Ber}(q) \right) = \sigma'.$$
Proof of (156). To control $\sigma'$, we plug in the assumptions in (123) and $\beta \geq 4$ and arrive at the trivial facts

$$\left(\frac{1}{\beta}\right) \log \left(\frac{1}{\beta}\right) - \left(\frac{1}{\beta}\right) \log(q) < 0, \quad \left(1 - \frac{1}{\beta}\right) \log \left(1 - \frac{1}{\beta}\right) < 0.$$ 

The above facts directly lead to

$$\sigma' \leq \left(1 - \frac{1}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right). \quad (158)$$

Similarly, observing

$$-1 \leq \left(\frac{1}{\beta}\right) \log \left(\frac{1}{\beta}\right) + \left(1 - \frac{1}{\beta}\right) \log \left(1 - \frac{1}{\beta}\right) \leq 0, \quad -\left(\frac{1}{\beta}\right) \log(q) \geq 0,$$

we arrive at

$$\sigma' \geq -1 + \left(1 - \frac{1}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right) \geq \left(1 - \frac{2}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right) \quad (159)$$

as long as $\log \left(\frac{1}{\alpha + \Delta}\right) \geq \beta$ (cf. (122)). With (158) and (159) in hand, it is straightforward to see that the choice of the uncertainty radius $\sigma$ in (132) obeys the advertised bound (156).

### B.3.5 Proof of Lemma 12

For notational conciseness, we shall drop the superscript $\phi$ and use the shorthand $V_{h}^{\pi,\sigma} = V_{h}^{\pi,\sigma,\phi}$ and $V_{h}^{\ast,\sigma} = V_{h}^{\ast,\sigma,\phi}$ whenever it is clear from the context. We begin by deriving the robust value function for any policy $\pi$. Starting with state 1, at any step $h \in [H]$, it obeys

$$V_{h}^{\pi,\sigma}(1) = \mathbb{E}_{a \sim \pi_{h}(\cdot | 1)} \left[ r_{h}(1, a) + \inf_{P \in \mathcal{U}(P^{\phi}_{h,1,a})} \mathcal{P}V_{h+1}^{\pi,\sigma} \right] = 0 + V_{h+1}^{\pi,\sigma},$$

where the first equality follows from the robust Bellman consistency equation (cf. (8)), and the second equality follows from the observation that the distribution $P^{\phi}_{h,1,a}$ is supported solely on state 1 in view of (119a), therefore $\mathcal{U}(P^{\phi}_{h,1,a}) = P^{\phi}_{h,1,a}$. Leveraging the terminal condition $V_{H+1}^{\pi,\sigma}(1) = 0$, and recursively applying the previous relation, we have

$$V_{h}^{\ast,\sigma}(1) = V_{h}^{\pi,\sigma}(1) = 0, \quad \forall h \in [H]. \quad (160)$$

Similarly, turning to state 0, at any step $h > 1$, the robust value function satisfies

$$V_{h}^{\pi,\sigma}(0) = \mathbb{E}_{a \sim \pi_{h}(\cdot | 0)} \left[ r_{h}(0, a) + \inf_{P \in \mathcal{U}(P^{\phi}_{h,0,a})} \mathcal{P}V_{h+1}^{\pi,\sigma} \right] = 1 + V_{h+1}^{\pi,\sigma},$$

which again uses the fact that the distribution $P^{\phi}_{h,0,a}$ is supported solely on state 0 in view of (119b), therefore $\mathcal{U}(P^{\phi}_{h,0,a}) = P^{\phi}_{h,0,a}$. Leveraging the terminal condition $V_{H+1}^{\pi,\sigma}(0) = 0$, and recursively applying the previous relation, we have

$$V_{h}^{\ast,\sigma}(0) = V_{h}^{\pi,\sigma}(0) = H - h + 1, \quad 2 \leq h \leq H. \quad (161)$$

Taking (160) and (161) together, it follows that

$$\forall 2 \leq h \leq H : \quad V_{h}^{\pi,\sigma}(0) > V_{h}^{\pi,\sigma}(1). \quad (162)$$
Consequently, the robust value function of state 0 at step \( h = 1 \) satisfies

\[
V_1^{\pi,\sigma}(0) = E_{u \sim \pi_1(\cdot | 0)} \left[ r_1(0, a) + \inf_{P \in U^\sigma(P_1^{\pi,\sigma})} PV_2^{\pi,\sigma} \right]
\]

\[
\overset{(i)}{=} 1 + \pi_1(\phi | 0) \left( \inf_{P \in U^\sigma(P_1^{\pi,\sigma})} PV_2^{\pi,\sigma} \right) + \pi_1(1 - \phi | 0) \left( \inf_{P \in U^\sigma(P_1^{\pi,\sigma})} PV_2^{\pi,\sigma} \right)
\]

\[
\overset{(ii)}{=} 1 + \pi_1(\phi | 0) \left[ PV_2^{\pi,\sigma}(0) + (1 - p) PV_2^{\pi,\sigma}(1) \right] + \pi_1(1 - \phi | 0) \left[ q V_2^{\pi,\sigma}(0) + (1 - q) V_2^{\pi,\sigma}(1) \right]
\]

\[
= 1 + z^\pi_0 V_2^{\pi,\sigma}(0)
\]

\[
(163)
\]

where (i) uses the definition of the reward function in (124), (ii) uses (162) so that the infimum is attained by picking the choice specified in (134) with a smallest probability mass imposed on the transition to state 0. Finally, we plug in the definition (136) of \( z^\pi_0 \) in (iii), and the last line follows from (160).

Therefore, taking \( \pi = \pi^{\ast,\phi} \) in the previous relation directly leads to

\[
V_1^{\pi,\sigma}(0) = 1 + z^\pi_0 V_2^{\pi,\sigma}(0) = 1 + z^\pi_0 (H - 1),
\]

where the second equality follows from (161). Observing that the function \((H - 1) z\) is increasing in \( z \) and that \( z^\pi_0 \) is increasing in \( \pi_1(\phi | 0) \) (due to the fact \( p \geq q \) in (135)). As a result, the optimal policy obeys

\[
\pi^{\ast,\phi}_1(\phi | 0) = 1
\]

(165)

at state 0, and plugging back to (164) gives

\[
V_1^{\pi,\sigma}(0) = 1 + z^\pi_0 (H - 1) = 1 + p(H - 1),
\]

where \( z^\pi_0 = p \pi^{\ast,\phi}_1(\phi | 0) + q \pi^{\ast,\phi}_1(1 - \phi | 0) = p \). For the rest of the states, without loss of generality, we choose the optimal policy obeying

\[
\forall h \in [H] : \quad \pi^{\ast,\phi}_h(\phi | 0) = 1, \quad \pi^{\ast,\phi}_h(\phi | 1) = 1.
\]

(166)

**Proof of claim (139).** Given that \( \pi^{\ast,\phi}_h(\phi | 0) = 1 \) for all \( h \in [H] \) and \( \rho(0) = 1 \), for any \( P \in U^\sigma(P^\phi) \), we have

\[
d^*_2(P, \phi) = d^*_2(P)(0) \pi^{\ast,\phi}_2(\phi | 0) = d^*_2(P)(0) = P_{s_2 \sim P(\cdot | s_1, \pi^{\ast,\phi}_1(s_1))} \{ s_2 = 0 | s_1 \sim \rho; \pi^{\ast,\phi} \}
\]

\[
= P_1(0 | 0, \phi) \overset{(i)}{\geq} P^\phi_1(0 | 0, \phi) \overset{(ii)}{=} \frac{p}{\beta} \overset{(i)}{\geq} \frac{1}{\beta},
\]

(167)

which (i) holds by plugging in the definition (133), (ii) follows from the definition (134), and the final inequality arises from Lemma 11. Hence, for all \( 2 \leq h \leq H \), by the Markov property and \( P^\phi_h(0 | 0, \phi) = 1 \), we have

\[
d^*_h(P, \phi) = d^*_2(P)(0, \phi) \geq \frac{1}{\beta}.
\]

(168)

Examining the definition of \( C_{\text{rob}}^* \) in (12), we make the following observations.

- For \( h = 1 \), we have

\[
\max_{(s,a,P) \in S \times A \times U^\sigma(P^\phi)} \min \left\{ d^*_1(P)(s,a), \frac{1}{2} \right\} \overset{(i)}{=} \max_{P \in U^\sigma(P^\phi)} \min \left\{ d^*_1(P)(0,\phi), \frac{1}{2} \right\} \overset{(ii)}{=} \max_{P \in U^\sigma(P^\phi)} \frac{1}{S \mu(0)} \overset{(iii)}{=} 2C
\]

(169)

where (i) holds by \( d^*_1(P)(s) = \rho(s) = 0 \) for all \( s \in S \setminus \{0\} \) (see (129)) and \( \pi^{\ast,\phi}_h(\phi | 0) = 1 \) for all \( h \in [H] \), (ii) follows from the fact \( d^*_1(P,0,\phi) = 1 \), (iii) is verified in (128), and the last equality arises from the definition in (126).
• Similarly, for \( h = 2 \), we arrive at
\[
\max_{(s,a,P) \in S \times A \times U^* (P^o)} \min \left\{ \frac{d^{*P}_h (s,a)}{d^{P^o}_h (s,a)} \frac{1}{\frac{1}{2}} \right\} = \max_{s \in \{0,1\}, P \in U^*(P^o)} \min \left\{ \frac{d^{*P}_2 (s,\phi)}{d^{P^o}_2 (s,\phi)} \right\} \\
\leq \max_{s \in \{0,1\}, P \in U^*(P^o)} \frac{1}{S d^{P^o}_2 (s,\phi)} \leq \frac{4}{S} \mu (0) = 4C, \quad (170)
\]
where (i) holds by the optimal policy in (138) and the trivial fact that \( d^{*P}_2 (s) = 0 \) for all \( s \in S \setminus \{0,1\} \) (see (129) and (119a)), (ii) arises from (128), and the last equality comes from (126).

• For all other steps \( h = 3, \ldots, H \), observing from the deterministic transition kernels in (119b), it can be easily verified that
\[
\max_{(s,a,P) \in S \times A \times U^* (P^o)} \min \left\{ \frac{d^{*P}_h (s,a)}{d^{P^o}_h (s,a)} \frac{1}{\frac{1}{2}} \right\} = \max_{(s,a,P) \in S \times A \times U^* (P^o)} \min \left\{ \frac{d^{*P}_2 (s,a)}{d^{P^o}_2 (s,a)} \right\} \leq 4C. \quad (171)
\]
Combining the above cases, we complete the proof by
\[
2C \leq C^*_\text{rob} = \max_{(h,s,a,P) \in [H] \times S \times A \times U^* (P^o)} \min \left\{ \frac{d^{*P}_h (s,a)}{d^{P^o}_h (s,a)} \frac{1}{\frac{1}{2}} \right\} \leq 4C.
\]

### B.3.6 Proof of the claim (142)
Recall that by virtue of (136) and (138), we arrive at
\[
z_\phi^* := z_\phi^* = p_1 \pi_1^* (\phi | 0) + q_1 1 - \pi_1 (0). \quad (172)
\]
Applying (137) yields
\[
\langle \rho, V_1^*, \sigma, \phi - V_1^*, \sigma, \phi \rangle = V_1^*, \sigma, \phi (0) - V_1^*, \sigma, \phi (0) = (p - z_\phi^*) (H - 1) = (p - q) (H - 1) (1 - \pi_1 (0)),
\]
where the last equality uses the definition (136). Therefore, it boils down to control \( p - q \).

To continue, we define an auxiliary value function vector \( \underline{\nabla} \in \mathbb{R}^{S \times 1} \) obeying
\[
\underline{\nabla} (0) = H - 1 \quad \text{and} \quad \underline{\nabla} (s) = 0, \quad \forall s \in S \setminus \{0\}. \quad (173)
\]
With this in hand, applying Lemma 4 gives
\[
(H - 1) \left( \frac{\rho - q}{2} \right) = \inf_{P \in \mathcal{U}^* (P_{1,0,\phi})} P \underline{\nabla} - \inf_{P \in \mathcal{U}^* (P_{1,0,1-\phi})} P \underline{\nabla}
\[
= \sup_{\lambda \geq 0} \left\{ - \lambda \log \left( P_{1,0,\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda} \right) \right) - \lambda \sigma \right\} - \sup_{\lambda \geq 0} \left\{ - \lambda \log \left( P_{1,0,1-\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda} \right) \right) - \lambda \sigma \right\}
\[
\geq \left\{ - \lambda^* \log \left( P_{1,0,\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda^*} \right) \right) - \lambda^* \sigma \right\} - \left\{ - \lambda^* \log \left( P_{1,0,1-\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda^*} \right) \right) - \lambda^* \sigma \right\}
\[
= - \lambda^* \left[ \log \left( P_{1,0,\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda^*} \right) \right) \right] - \log \left( P_{1,0,1-\phi} \cdot \exp \left( - \frac{\underline{\nabla}}{\lambda^*} \right) \right), \quad (174)
\]
where (i) follows from (see the definition of \( p \) in (134))
\[
\inf_{P \in \mathcal{U}^* (P_{1,0,\phi})} P \underline{\nabla} = P_1 (0 | 0, \phi) \underline{\nabla} (0) = (H - 1) \rho,
\]
\[
\inf_{P \in \mathcal{U}^* (P_{1,0,1-\phi})} P \underline{\nabla} = P_1 (0 | 0, 1 - \phi) \underline{\nabla} (0) = (H - 1) q.
\]
Here, (ii) holds by letting

\[ \lambda^* := \arg \max_{\lambda \geq 0} f(\lambda) := \arg \max_{\lambda \geq 0} \left\{ -\lambda \log \left( P_{1,0,1-\phi}^{\phi} \cdot \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right\}. \]  

(175)

The rest of the proof is then to control (174). We start with the observation that \( \lambda^* > 0 \); this is because in view of Lemma 5 (cf. (63)), it suffices to verify that

\[ \log(1 - q) + \sigma \leq \log(\alpha + \Delta) + \left( 1 - \frac{2}{\beta} \right) \log \left( \frac{1}{\alpha + \Delta} \right) = -\frac{2}{\beta} \log \left( \frac{1}{\alpha + \Delta} \right) < 0, \]

(176)

where (i) holds by (132). We now claim the following bound for \( \lambda^* \) holds, whose proof is postponed to the end:

\[ \frac{H}{16\sigma} \leq \frac{H - 1}{\log \left( \frac{\sigma}{\alpha + \Delta} \right)} \leq \lambda^* \leq \frac{H - 1}{\left( 1 - \frac{3}{\beta} \right) \log \left( \frac{1}{\alpha + \Delta} \right)}, \]

(177)

which immediately implies the following by taking exponential maps given \( \lambda^* > 0 \):

\[ \frac{\alpha + \Delta}{\beta} \leq e^{-(H-1)/\lambda^*} \leq (\alpha + \Delta)^{1 - 3/\beta}. \]

(178)

Moving to the second term of (174), it follows that

\[
\log \left( P_{1,0,\phi}^{\phi} \cdot \exp \left( -\frac{V}{\lambda^*} \right) \right) - \log \left( P_{1,0,1-\phi}^{\phi} \cdot \exp \left( -\frac{V}{\lambda^*} \right) \right) \overset{(i)}{=} \log \left( 1 + \frac{(p - q) e^{-(H-1)/\lambda^*} - 1}{q e^{-(H-1)/\lambda^*} + (1 - q)} \right) \\
\overset{(ii)}{=} -\frac{\Delta}{q e^{-(H-1)/\lambda^*} + (1 - q)} \\
\overset{(iii)}{\leq} -\frac{1}{2} \left( \frac{1}{\alpha + \Delta} \right)^{\frac{3}{2}} (1 - q) + (1 - q) \\
\leq -\frac{\Delta}{4e^6(1 - q)},
\]

(179)

where (i) follows from the definitions in (119) and (173), (ii) holds by \( \log(1 + x) < x \) for \( x \in (-1, \infty) \), (iii) can be verified by (178), \( \beta \geq 4 \), and (121):

\[ 1 - e^{-(H-1)/\lambda^*} \geq 1 - (\alpha + \Delta)^{1 - 3/\beta} \geq 1 - (\alpha + \Delta)^{1/4} \geq 1 - \left( \frac{3}{2H} \right)^{1/4} \geq \frac{1}{2}, \]

and the last line uses \( \left( \frac{1}{\alpha + \Delta} \right)^{\frac{3}{2}} = \left( \frac{1}{\alpha + \Delta} \right)^{6/\log \left( \frac{1}{\alpha + \Delta} \right)} = e^6 \) by the definition of \( \beta \) in (122). Plugging (177) and (179) back into (174) and (172), we arrive at

\[
\langle \rho, V_1^{\lambda^*,\phi} - V_1^{\pi,\sigma,\phi} \rangle = (H - 1) \left( p - q \right) (1 - \pi_1(\phi | 0)) \\
\geq \frac{H \Delta}{64e^6\sigma(1 - q)} (1 - \pi_1(\phi | 0)) = 2\varepsilon (1 - \pi_1(\phi | 0)),
\]

where (i) holds by (177) and the last equality follows directly from the choice of \( \Delta \) in (141).
Proof of inequality (177). Applying (62) in Lemma 5 to \( \lambda^* \) in (175) leads to the upper bound in (177):

\[
\lambda^* \leq \frac{H - 1}{\sigma} \leq \frac{H - 1}{\left(1 - \frac{3}{\beta}\right) \log \left(\frac{1}{\alpha + \Delta}\right)},
\]

where the last inequality holds by (132). As a result, we shall focus on showing the lower bounds in (177) in the remainder of the proof.

Recalling the definition of \( q \) in (120), we can reparameterize \( 1 - q \) using two positive variables \( c_q \) and \( \lambda_q \) (whose choices will be made clearer soon) as follows:

\[
1 - q = \alpha = c_q e^{-(H-1)/\lambda_q}.
\]

Deriving the first derivative of the function of interest \( f(\lambda) \) in (175) as follows:

\[
\nabla_{\lambda} f(\lambda) = \nabla_{\lambda} \left( -\lambda \log \left( P_{1,0,1-\phi} \cdot \exp \left( -\frac{V}{\lambda} \right) \right) - \lambda \sigma \right)
\]

\[
\overset{(i)}{=} \nabla_{\lambda} \left( -\lambda \log \left( q e^{-(H-1)/\lambda} + 1 - q \right) - \lambda \sigma \right)
\]

\[
= -\sigma - \log \left( q e^{-(H-1)/\lambda} + 1 - q \right) - \frac{1}{\lambda} \cdot q \left( H - 1 \right) e^{-(H-1)/\lambda} + 1 - q,
\]

where (i) holds by the chosen transition kernels in (119) and the last line arises from basic calculus. To continue, when \( \lambda = \lambda_q \), the derivative of the function \( f(\lambda) \) can be expressed as

\[
\nabla_{\lambda} f(\lambda) \mid_{\lambda=\lambda_q} = -\sigma - \log \left( 1 - q \frac{q}{c_q} + 1 - q \right) + \frac{(1 - q) \frac{q}{c_q} \log \frac{1-q}{c_q}}{(1 - q) \frac{q}{c_q} + 1 - q}
\]

\[
= -\sigma - \log(1 - q) - \log \left( 1 + \frac{q}{c_q} \right) + \frac{\frac{q}{c_q} \log \frac{1-q}{c_q}}{\frac{q}{c_q} + 1}
\]

\[
= -\sigma - \log(1 - q) \left( 1 - \frac{q/c_q}{q/c_q + 1} \right) - \log \left( 1 + \frac{q}{c_q} \right) - \frac{\frac{q}{c_q} \log(c_q)}{1 + q/c_q}
\]

\[
\overset{(i)}{=} -\sigma + \log \left( \frac{1}{\alpha + \Delta} \right) \left( 1 - \frac{q/c_q}{q/c_q + 1} \right) - \log \left( 1 + \frac{q}{c_q} \right) - \frac{\frac{q}{c_q} \log(c_q)}{1 + q/c_q}
\]

\[
\overset{(ii)}{=} \log \left( \frac{1}{\alpha + \Delta} \right) \left( \frac{2}{\beta} \frac{q/c_q}{q/c_q + 1} \right) - \log(1 + \frac{q}{c_q}) - \frac{\frac{q}{c_q} \log(c_q)}{1 + q/c_q}
\]

\[
\overset{(iii)}{=} \frac{1}{\beta} \log \left( \frac{1}{\alpha + \Delta} \right) - \log(1 + \frac{1}{\beta}) - 1
\]

\[
\overset{(iii)}{=} \frac{1}{\beta} \log \left( \frac{1}{\alpha + \Delta} \right) - 2 = 0,
\]

where (i) holds by (181), (ii) follows from the bound of \( \sigma \) in (132), (iii) arises from letting \( c_q = \beta \geq 4 \) and noting the fact \( 1/2 \leq q < 1 \) (see (123)), leading to

\[
\frac{1}{2\beta} \leq \frac{q}{c_q} < \frac{1}{\beta}, \quad \frac{q/c_q}{q/c_q + 1} \leq \frac{1}{\beta}, \quad \frac{\frac{q}{c_q} \log(c_q)}{1 + q/c_q} < 1.
\]

Finally, the last line holds by \( 1/\beta \leq \frac{1}{4} \) and \( \log \left( \frac{1}{\alpha + \Delta} \right) = 2\beta \) (see (122)).

To proceed, note that the function \( f(\lambda) \) is concave with respect to \( \lambda \). Therefore, observing \( \nabla_{\lambda} f(\lambda) \mid_{\lambda=\lambda_q} \geq 0 \) with \( c_q = \beta \), we have \( \lambda_q \leq \lambda^* \), which implies (see (181))

\[
1 - q = \alpha + \Delta = \beta e^{-(H-1)/\lambda_q} \leq \beta e^{-(H-1)/\lambda^*}.
\]
The above assertion directly gives
\[ \lambda^* \geq \frac{H - 1}{\log \left( \frac{\beta}{\alpha + \Delta} \right)}. \]

The proof is completed by noticing
\[ \frac{H - 1}{\log \left( \frac{\beta}{\alpha + \Delta} \right)} = \frac{H - 1}{\log \left( \frac{1}{\alpha + \Delta} \right)} + \log \beta \geq \frac{H - 1}{2\log \left( \frac{1}{\alpha + \Delta} \right)} \geq \frac{H}{16\sigma}, \]
where (i) follows from (122), and the last inequality follows from (132) and the fact \( \beta \in [4, \infty) \).

C Analysis: discounted infinite-horizon RMDPs

C.1 Proof of Lemma 2

We shall first show that the operator \( \hat{T}_{pe}^\sigma(\cdot) \) (cf. (44)) is a \( \gamma \)-contraction, which will in turn imply the existence of the unique fixed point of \( \hat{T}_{pe}^\sigma(\cdot) \). Before starting, suppose that the entries of \( Q_1, Q_2 \in \mathbb{R}^{S \times A} \) are all bounded in \([0, \frac{1}{1-\gamma}]\) for all \((s, a) \in S \times A\). Denote that
\[ \forall s \in S : \quad V_1(s) := \max_a Q_1(s, a), \quad V_2(s) := \max_a Q_2(s, a). \] (187)

Proof of \( \gamma \)-contraction. We first show that \( \hat{T}_{pe}^\sigma(\cdot) \) is a \( \gamma \)-contraction. Towards this, instead of \( \hat{T}_{pe}(\cdot) \), we begin with a simpler operator \( \hat{T}_{pe}^\sigma(\cdot) \), defined as follows:
\[ \forall (s, a) \in S \times A : \quad \hat{T}_{pe}^\sigma(Q)(s, a) = r(s, a) + \gamma \inf_{P \in U^\sigma(P_0)} PV - b(s, a), \] (188)
which consequently leads to
\[ \forall (s, a) \in S \times A : \quad \hat{T}_{pe}^\sigma(Q)(s, a) = \max \left\{ \hat{T}_{pe}^\sigma(Q)(s, a), 0 \right\}. \] (189)

It follows straightforwardly that
\[ \left\| \hat{T}_{pe}^\sigma(Q_1) - \hat{T}_{pe}^\sigma(Q_2) \right\|_\infty \leq \left\| \hat{T}_{pe}^\sigma(Q_1) - \hat{T}_{pe}^\sigma(Q_2) \right\|_\infty, \] (190)
and hence it suffices to establish the \( \gamma \)-contraction of \( \hat{T}_{pe}^\sigma(\cdot) \). With this in mind, we observe that
\[ \left\| \hat{T}_{pe}^\sigma(Q_1) - \hat{T}_{pe}^\sigma(Q_2) \right\|_\infty \leq \gamma \left\| \inf_{P \in U^\sigma(P_0)} PV_1 - \inf_{P \in U^\sigma(P_0)} PV_2 \right\|_\infty \]
\[ \overset{(i)}{=} \gamma \max_{s, a} \left| Q_1(s, a) - Q_2(s, a) \right| \]
\[ \leq \gamma \max_{(s, a)} \left| Q_1(s, a) - Q_2(s, a) \right| = \gamma \| Q_1 - Q_2 \|_\infty, \] (191)
where the first equality holds by the definition of \( \hat{T}_{pe}^\sigma(\cdot) \) (cf. (188)), (i) follows from that the infimum operator is a 1-contraction w.r.t. \( \| \cdot \|_\infty \) and \( \| PV_1 - PV_2 \|_\infty \leq \| V_1 - V_2 \|_\infty \) for all \( P \in \Delta(S) \), (ii) arises from the definitions in (187), and the last inequality is due to the maximum operator is also a 1-contraction w.r.t. \( \| \cdot \|_\infty \). Combining the above two inequalities establish the desired statement.
Existence of the unique fixed point. To continue, we shall first claim that there exists at least one fixed point of \( \hat{T}_{pe}(\cdot) \). This is a standard argument, which we omit for brevity; interested readers are encouraged to refer to, e.g., Li et al. (2022), for details.

To prove the uniqueness of the fixed points of \( \hat{T}_{pe}(\cdot) \), suppose that there exist two fixed points \( Q' \) and \( Q'' \) obeying \( Q' = \hat{T}_{pe}(Q') \) and \( Q'' = \hat{T}_{pe}(Q'') \). Moreover, the definition of \( \hat{T}_{pe}(\cdot) \) directly implies \( 0 \leq Q', Q'' \leq \frac{1}{1-\gamma} \), since for any \( 0 \leq Q \leq \frac{1}{1-\gamma} \), it follows that \( 0 \leq \hat{T}_{pe}(Q) \leq \frac{1}{1-\gamma} \). By the \( \gamma \)-contraction property, it follows that
\[
\|Q' - Q''\|_\infty = \left\| \hat{T}_{pe}(Q') - \hat{T}_{pe}(Q'') \right\|_\infty \leq \gamma \|Q' - Q''\|_\infty.
\] (192)

However, (192) can't happen given \( \gamma \in \left[\frac{1}{2}, 1\right) \), indicating the uniqueness of the fixed points of \( \hat{T}_{pe}(\cdot) \).

C.2 Proof of Lemma 3

To begin with, considering any \( Q, Q' \) obeying \( Q \leq Q' \), and \( 0 \leq Q, Q' \leq \frac{1}{1-\gamma} \). We observe that the operator \( \hat{T}_{pe}(\cdot) \) (cf. (44)) has the monotone non-decreasing property, namely,
\[
\hat{T}_{pe}(Q)(s, a) = \max \left\{ r(s, a) + \gamma \inf_{P \in U^* \left( P_{0, a} \right)} PV - b(s, a), 0 \right\}
= \max \left\{ r(s, a) + \gamma \inf_{P \in U^* \left( P_{0, a} \right)} \mathcal{P} \max Q(\cdot, a') - b(s, a), 0 \right\}
\leq \max \left\{ r(s, a) + \gamma \inf_{P \in U^* \left( P_{0, a} \right)} \mathcal{P} \max Q'(\cdot, a') - b(s, a), 0 \right\} = \hat{T}_{pe}(Q')(s, a),
\] (193)

where the last line uses \( Q \leq Q' \). Recalling the fixed point \( \hat{Q}_{pe}^* \) of \( \hat{T}_{pe}(\cdot) \), armed with (193) and the initialization \( \hat{Q}_0 = 0 \), we arrive at
\[
\hat{Q}_1 = \hat{T}_{pe}(\hat{Q}_0) \leq \hat{T}_{pe}(\hat{Q}_{pe}^*) = \hat{Q}_{pe}^*.
\]
where the inequality follows from \( \hat{Q}_0 = 0 \leq \hat{Q}_{pe}^* \). Implementing the above result recursively gives
\[
\forall \, m \geq 0 : \quad \hat{Q}_m \leq \hat{Q}_{pe}^*.
\]

Applying the \( \gamma \)-contraction property in Lemma 2 thus yields that for any \( m \geq 0 \),
\[
\|\hat{Q}_m - \hat{Q}_{pe}^*\|_\infty = \left\| \hat{T}_{pe}(\hat{Q}_{m-1}) - \hat{Q}_{pe}^* \right\|_\infty \leq \gamma \|\hat{Q}_{m-1} - \hat{Q}_{pe}^*\|_\infty
\leq \cdots \leq \gamma^m \|\hat{Q}_0 - \hat{Q}_{pe}^*\|_\infty = \gamma^m \|\hat{Q}_{pe}^*\|_\infty \leq \frac{\gamma^m}{1-\gamma},
\]
where the last inequality holds by the fact \( \|\hat{Q}_{pe}^*\|_\infty \leq \frac{1}{1-\gamma} \) (see Lemma 2).

C.3 Proof of Theorem 3

To begin, we introduce some additional notation that will be useful throughout the analysis. We denote the state-action space covered by the batch dataset \( \mathcal{D} \) as
\[
\mathcal{C}^b = \left\{ (s, a) : \hat{q}_b(s, a) > 0 \right\}.
\] (194)

In addition, recalling the definition in (45), we define a similar one based on the true nominal model \( P_0 \) as
\[
P_{\min}(s, a) := \min_{s'} \left\{ P_0(s' | s, a) : P_0(s' | s, a) > 0 \right\},
\] (195)
which directly indicates that
\[
P_{\min}^* = \min_s P_{\min}(s, \pi^*(s)), \quad P_{\min}^b = \min_{(s,a) \in C^b} P_{\min}(s,a). \tag{196}
\]

Next, we denote the set of possible state occupancy distributions associated with the optimal policy \(\pi^*\) in a model within the uncertainty set \(P \in \mathcal{U}^*(P^0)\) as
\[
\mathcal{D}^* := \left\{ [d^{*,P}(s)]_{s \in \mathcal{S}} : P \in \mathcal{U}^*(P^0) \right\} = \left\{ [d^{*,P}(s, \pi^*(s))]_{s \in \mathcal{S}} : P \in \mathcal{U}^*(P^0) \right\}, \tag{197}
\]
where the second equality is due to the fact that \(\pi^*\) is chosen to be deterministic.

We are now ready to embark on the proof of Theorem 3. We first introduce a fact that is used throughout the proof; the proof is postponed to Appendix C.3.2:
\[
\forall (s, a) \in \mathcal{C}^b : \quad N(s, a) \geq \frac{N_{\hat{P}}(s, a)}{12} \geq c_1 \log(NS/\delta) \geq -\frac{\log 2NS}{\log(1 - P_{\min}(s, a))} \tag{198}
\]
as long as \((56)\) holds.

For notation simplicity, denote the output Q-function and value function from Algorithm 2 as \(\hat{Q} = \hat{Q}_M\) and \(\hat{V} = \hat{V}_M\). Invoking Lemma 3 with \(M \geq \frac{\log 2NS}{\log \frac{1}{\gamma}}\) directly leads to
\[
\|\hat{Q} - \hat{Q}_{pe}^{*,\sigma}\|_\infty \leq \frac{1}{\sigma N} \tag{199}
\]
and therefore
\[
\|\hat{V} - \hat{V}_{pe}^{*,\sigma}\|_\infty \leq \max_s \left\{ \max_a \hat{Q}(s, a) - \max_a \hat{Q}_{pe}^{*,\sigma}(s, a) \right\} \leq \|\hat{Q} - \hat{Q}_{pe}^{*,\sigma}\|_\infty \leq \frac{1}{\sigma N}. \tag{200}
\]

The proof of Theorem 3 is separated into several key steps as follows.

**Step 1: controlling the uncertainty via leave-one-out analysis.** Given access to only a finite number of samples for estimating the nominal transition kernel \(P^0\), we need to efficiently control
\[
\left| \inf_{P \in \mathcal{U}^*(P^0)} \mathcal{P} \hat{V} - \inf_{P \in \mathcal{U}^*(P^0)_{s,a}} \mathcal{P} \hat{V} \right|
\]
across the robust value iterations, where \(\hat{V}\) is statistically dependent on \(\hat{P}^0\) (since \(\hat{P}^0_{s,a}\) will be reused in the update rule (cf. (49)) for all the iterations). A naive treatment via the standard covering arguments will unfortunately lead to rather loose bounds (Panaganti and Kalathil, 2022; Yang et al., 2021; Zhou et al., 2021). To overcome this challenge, we resort to the leave-one-out analysis—pioneered by Agarwal et al. (2020); Li et al. (2022, 2020) in the context of model-based RL—to decouple the statistical dependency. The results are summarized in the following lemma, with the proof provided in Appendix C.3.1.

**Lemma 13.** *Instate the assumptions in Theorem 3. Then for all vector \(\bar{V}\) obeying \(\|\bar{V} - \hat{V}_{pe}^{*,\sigma}\|_\infty \leq \frac{1}{\sigma N}\) and \(\|\bar{V}\|_\infty \leq \frac{1}{1 - \gamma}\), with probability at least \(1 - \delta\), one has
\[
\left| \inf_{P \in \mathcal{U}^*(P^0_{s,a})} \mathcal{P} \bar{V} - \inf_{P \in \mathcal{U}^*(P^0_{s,a})} \mathcal{P} \bar{V} \right| \leq \min \left\{ \frac{c_0}{\sigma(1 - \gamma)} \sqrt{\frac{1}{\hat{P}_{\min}(s, a)N(s, a)}} + \frac{4}{N\sigma(1 - \gamma)} \right\} \tag{201}
\]
for all \((s, a) \in \mathcal{S} \times \mathcal{A}\). In addition, for all \((s, a) \in \mathcal{C}^b\), with probability at least \(1 - \delta\), one has
\[
\frac{P_{\min}(s, a)}{8 \log( NS/\delta )} \leq \hat{P}_{\min}(s, a) \leq e^2 P_{\min}(s, a). \tag{202}
\]
**Step 2: establishing the pessimism property.** Armed with Lemma 13, we aim to show the key property that

\[
\forall (s,a) \in S \times A : \quad \hat{Q}(s,a) \leq \hat{Q}^{\hat{\pi},\sigma}(s,a), \quad \hat{V}(s) \leq V^{\hat{\pi},\sigma}(s). \quad (203)
\]

Similar to the finite-horizon setting, it suffices to focus on verifying the former assertion in (203). Towards this, we first recall that the fixed point \(\hat{Q}^{*,\sigma}_{pe}\) of the pessimistic robust Bellman operator \(\hat{T}^{\sigma}_{pe}(\cdot)\) (cf. (44)) obeys

\[
\hat{Q}^{*,\sigma}_{pe} = \hat{T}^{\sigma}_{pe}(\hat{Q}^{*,\sigma}_{pe}) = \max \left\{ r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V}^{*,\sigma}_{pe} - b(s,a), 0 \right\}. \quad (204)
\]

If \(\hat{Q}^{*,\sigma}_{pe}(s,a) = 0\). Given the initialization \(\hat{Q}_0 = 0\), invoking Lemma 3 gives

\[
\hat{Q}(s,a) = \hat{Q}_M(s,a) \leq \hat{Q}^{*,\sigma}_{pe}(s,a) = 0.
\]

As a result, \(Q^{\hat{\pi},\sigma}(s,a) \geq 0 = \hat{Q}(s,a)\) as desired. Therefore, it boils down to examine the case when \(\hat{Q}^{*,\sigma}_{pe}(s,a) > 0\). One has

\[
\hat{Q}(s,a) \leq \hat{Q}^{*,\sigma}_{pe}(s,a) + \frac{1}{\sigma N} = r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V}^{*,\sigma}_{pe} - b(s,a) + \frac{1}{\sigma N}
\]

\[
\leq r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} - b(s,a) + \frac{1}{\sigma N} + \gamma \left| \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V}^{*,\sigma}_{pe} - \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} \right|
\]

\[
\leq r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} - b(s,a) + \frac{2}{\sigma N} + \gamma \left| \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} - \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} \right|
\]

\[
\leq r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V}, \quad (205)
\]

where (i) follows from (199), (ii) arises from (200) and the basic fact that infimum operator is 1-contraction w.r.t \(\| \cdot \|\infty\), and the last inequality holds by the definition of \(b(s,a)\) (cf. (46)) and Lemma 13. Putting the above inequality together with the robust Bellman equation (cf. (35a)) pertaining to \(Q^{\hat{\pi},\sigma}(s,a)\), we arrive at

\[
Q^{\hat{\pi},\sigma}(s,a) - \hat{Q}(s,a) \geq r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}V^{\hat{\pi},\sigma} - \left( r(s,a) + \gamma \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} \right)
\]

\[
= \gamma \left( \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}V^{\hat{\pi},\sigma} - \inf_{P \in U^*(P_{0,s,a})} \mathcal{P}\hat{V} \right)
\]

\[
\geq \gamma \hat{P}_{s,a} \left( V^{\hat{\pi},\sigma} - \hat{V} \right), \quad (i)
\]

where (i) holds by setting \(\hat{P}_{s,a} = \arg\min_{P \in U^*(P_{0,s,a})} \mathcal{P}V^{\hat{\pi},\sigma}\). Consequently, one has

\[
\min_{s,a} \left[ Q^{\hat{\pi},\sigma}(s,a) - \hat{Q}(s,a) \right] \geq \min_{s,a} \left[ \gamma \hat{P}_{s,a} \left( V^{\hat{\pi},\sigma} - \hat{V} \right) \right] \geq \gamma \min_{s} \left[ V^{\hat{\pi},\sigma}(s) - \hat{V}(s) \right]
\]

\[
= \gamma \min_{s} \left[ Q^{\hat{\pi},\sigma}(s, \hat{\pi}(s)) - \hat{Q}(s, \hat{\pi}(s)) \right]
\]

\[
\geq \gamma \min_{s,a} \left[ Q^{\hat{\pi},\sigma}(s,a) - \hat{Q}(s,a) \right], \quad (206)
\]

where (i) follows from \(\hat{P}_{s,a} \in \Delta(S)\) for all \((s,a) \in S \times A\). Noting that \(0 \leq \gamma < 1\), we conclude \(Q^{\hat{\pi},\sigma}(s,a) - \hat{Q}(s,a) \geq 0\) for all \((s,a) \in S \times A\). This establishes the claim (203).
Step 3: bounding $V^{*,*}(\rho) - \hat{V}^{\pi,\sigma}(\rho)$. In view of the pessimistic property (cf. (203)), it follows that
\begin{equation}
V^{*,*}(s) - \hat{V}^{\pi,\sigma}(s) \leq V^{*,*}(s) - \hat{V}(s).
\end{equation}

Towards this, note that
\begin{align}
\hat{V}(s) &= \max_a Q(s, a) \geq \hat{Q}(s, \pi^*(s)) \geq \hat{Q}_{\pi}^{s,\sigma}(s, \pi^*(s)) - \frac{1}{\sigma N} \\
&\geq r(s, \pi^*(s)) + \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{1}{\sigma N} \\
&\geq r(s, \pi^*(s)) + \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{1}{\sigma N} \\
&\geq r(s, \pi^*(s)) + \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{2}{\sigma N} \\
&\geq r(s, \pi^*(s)) + \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{2}{\sigma N},
\end{align}

where (i) follows from (199), (ii) holds by applying (204), (iii) arises from (200), and the basic fact that the infimum operator is a 1-contraction w.r.t. $\| \cdot \|_{\infty}$, and the final inequality holds by the definition of $b(s, a)$ (see (46)) and Lemma 13.

To continue, invoking the robust Bellman optimality equation in (35b) gives
\begin{equation}
V^{*,*}(s) = Q^{*,\sigma}(s, \pi^*(s)) = r(s, \pi^*(s)) + \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{2}{\sigma N}.
\end{equation}

Combining the above relation with (208), we arrive at
\begin{align}
V^{*,*}(s) - \hat{V}(s) &\leq \gamma \inf_{P \in U^*} \hat{P}_{\pi}^{s,\sigma} - b(s, \pi^*(s)) - \frac{2}{\sigma N} \\
&\leq \gamma \hat{P}_{\pi,\pi^*}^{s,\sigma} \left( V^{*,*} - \hat{V} \right) + 2b(s, \pi^*(s)),
\end{align}

where the final inequality holds evidently, by introducing
\begin{equation}
\hat{P}_{\pi,\pi^*}^{s,\sigma} := \arg\min_{P \in U^*} \left( \hat{P}_{\pi}^{s,\sigma} \right) \hat{V}.
\end{equation}

Before continuing, for convenience, let us introduce a matrix $\hat{P}^{\pi,\sigma} \in \mathbb{R}^{s \times s}$ and a vector $b^* \in \mathbb{R}^s$, where their $s$-th rows (resp. entries) are defined as
\begin{equation}
\left[ \hat{P}^{\pi,\sigma} \right]_{s, \\ \\ } = \hat{P}_{\pi,\pi^*}^{s,\sigma}(s), \quad \text{and} \quad b(s) = b(s, \pi^*(s)).
\end{equation}

With these notation in hand, averaging (209) over the initial state distribution $\rho$ leads to
\begin{align}
V^{*,*}(\rho) - \hat{V}(\rho) &= \sum_{s \in S} \rho(s) \left( V^{*,*}(s) - \hat{V}(s) \right) \\
&\leq \gamma \sum_{s \in S} \rho(s) \hat{P}_{\pi,\pi^*}^{s,\sigma}(s) \left( V^{*,*} - \hat{V} \right) + 2 \sum_{s \in S} \rho(s)b(s, \pi^*(s)) \\
&= \gamma \rho^T \hat{P}^{\pi,\sigma} \left( V^{*,*} - \hat{V} \right) + 2 \rho^T b^*.
\end{align}
Applying the above result recursively gives

\[ V^{*,\sigma}(\rho) - \hat{V}(\rho) \leq \gamma \rho^T \hat{P}^{\inf} \left( V^{*,\sigma} - \hat{V} \right) + 2 \rho^T b^* \]

\[ \leq \gamma \left( \gamma \rho^T \hat{P}^{\inf} \right) \hat{P}^{\inf} \left( V^{*,\sigma} - \hat{V} \right) + 2 \left( \gamma \rho^T \hat{P}^{\inf} \right) b^* + 2 \rho^T b^* \]

\[ \leq \cdots \leq \left\{ \lim_{i \to \infty} \gamma^i \rho^T \left( \hat{P}^{\inf} \right)^i \left( V^{*,\sigma} - \hat{V} \right) \right\} + 2 \rho^T \sum_{i=0}^\infty \gamma^i \left( \hat{P}^{\inf} \right)^i b^* \]

\[ \leq 2 \rho^T \sum_{i=0}^\infty \gamma^i \left( \hat{P}^{\inf} \right)^i b^* = 2 \rho^T \left( I - \gamma \hat{P}^{\inf} \right)^{-1} b^*, \quad (213) \]

where (i) holds by \(|\rho^T \left( \hat{P}^{\inf} \right)^i \left( V^{*,\sigma} - \hat{V} \right) | \leq \frac{1}{1-\gamma} \) for all \( i \geq 0 \), and that \( \lim_{i \to \infty} \gamma^i \rho^T \left( \hat{P}^{\inf} \right)^i \left( V^{*,\sigma} - \hat{V} \right) = 0 \) since \( \lim_{i \to \infty} \gamma^i = 0 \) for all \( 0 \leq \gamma < 1 \).

To further characterize the above performance gap, invoking the definition of \( d^{*,P} \) (cf. (36) and (37a)), we arrive at

\[ \left( d^{*,\hat{P}^{\inf}} \right)^T = (1 - \gamma) \rho^T \sum_{t=0}^\infty \gamma^t \left( \hat{P}^{\inf} \right)^t = (1 - \gamma) \rho^T \left( I - \gamma \hat{P}^{\inf} \right)^{-1}. \quad (214) \]

Plugging the above expression back into (213), and combining with (207), yields

\[ V^{*,\sigma}(\rho) - V^{*,\pi}(\rho) \leq V^{*,\pi}(\rho) - \hat{V}(\rho) \leq \frac{2}{1-\gamma} \left\langle d^{*,\hat{P}^{\inf}}, b^* \right\rangle. \quad (215) \]

**Step 4: controlling \( \left\langle d^{*,\hat{P}^{\inf}}, b^* \right\rangle \) using concentrability.** Note that \( \hat{P}^{\inf} \in U^{\sigma}(P^0) \) (see (210) and (211)), which in words means \( \hat{P}^{\inf} \) is some transition kernel inside \( U^{\sigma}(P^0) \) — the uncertainty set around the nominal kernel \( P^0 \). Similar to the finite-horizon case, observing that we can express \( \left\langle d^{*,\hat{P}^{\inf}}, b^* \right\rangle = \sum_{s \in S} d^{*,\hat{P}^{\inf}}(s) b^*(s) \), we divide the states into two cases and control them separately.

- **Case 1**: \( s \in S \) where \( \max_{P \in U^{\sigma}(P^0)} d^{*,P}(s, \pi^*(s)) = 0 \). Since \( \hat{P}^{\inf} \in U^{\sigma}(P^0) \), one has

\[ 0 \leq d^{*,\hat{P}^{\inf}}(s) = d^{*,\hat{P}^{\inf}}(s, \pi^*(s)) \leq \max_{P \in U^{\sigma}(P^0)} d^{*,P}(s, \pi^*(s)) = 0, \]

which consequently indicates

\[ d^{*,\hat{P}^{\inf}}(s) = 0. \quad (216) \]

- **Case 2**: \( s \in S \) where \( \max_{P \in U^{\sigma}(P^0)} d^{*,P}(s, \pi^*(s)) > 0 \). For any such state \( s \), we claim that

\[ d^b(s, \pi^*(s)) > 0 \quad \text{and} \quad (s, \pi^*(s)) \in C^b. \quad (217) \]

This is due to Assumption 2, which requires \( C^*_\text{rob} \) to be finite given the numerator is positive:

\[ \max_{P \in U^{\sigma}(P^0)} \min \left\{ d^{*,P}(s, \pi^*(s)), \frac{1}{S} \right\} = \max_{P \in U^{\sigma}(P^0)} \min \left\{ d^{*,P}(s), \frac{1}{S} \right\} \leq C^*_\text{rob} < \infty. \quad (218) \]

To continue, invoking the fact in (198) with \( (s, \pi^*(s)) \in C^b \) gives

\[ N(s, \pi^*(s)) \geq \frac{N_d^b(s, \pi^*(s))}{12} \]

48
\[ \begin{aligned}
&\geq \frac{1}{12C_{\text{rob}}^*} \max_{P \in \mathcal{U}^*(P^0)} \min_{s} \left\{ d_{\ast, P}(s, \pi^\ast(s)), \frac{1}{3} \right\} \geq \frac{N \min \left\{ d_{\ast, \hat{P}^\ast}(s), \frac{1}{3} \right\}}{12C_{\text{rob}}^*},
\end{aligned} \tag{219} \]

where (i) holds by Assumption 2, and the last inequality holds by \( \hat{P}^\ast \in \mathcal{U}^*(P^0) \). With this in mind, we can control the pessimistic penalty \( b_{\ast}(s) \) (cf. (46)) by

\[ b_{\ast}(s) \leq \frac{c_b}{\sigma(1 - \gamma)} \left[ \frac{\log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)\delta} \right)}{P_{\min}(s, \pi^\ast(s))N(s, \pi^\ast(s))} + \frac{4}{\sigma N(1 - \gamma)} + \frac{2}{\sigma N} \right], \]

where (i) arises from (202), the penultimate inequality follows from (219), and the last inequality holds as long as \( c_b \) is large enough.

Summing up the above two cases, we arrive at

\[ \begin{aligned}
&\langle d_{\ast, \hat{P}^\ast}, b_{\ast} \rangle = \sum_{s \in S} d_{\ast, \hat{P}^\ast}(s)b_{\ast}(s) \\
&\leq \sum_{s \in S} d_{\ast, \hat{P}^\ast}(s) \left[ \frac{20c_b}{\sigma(1 - \gamma)} \left[ \frac{C_{\text{rob}}^* \log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)\delta} \right)}{P_{\min}(s, \pi^\ast(s))N \min \left\{ d_{\ast, \hat{P}^\ast}(s), \frac{1}{3} \right\}} \right] \right] \\
&\leq \frac{20c_b}{\sigma(1 - \gamma)} \sum_{s \in S} d_{\ast, \hat{P}^\ast}(s) \left[ \frac{C_{\text{rob}}^* \log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)\delta} \right)}{P_{\min}(s, \pi^\ast(s))N \min \left\{ d_{\ast, \hat{P}^\ast}(s), \frac{1}{3} \right\}} \right] \sqrt{\sum_{s \in S} d_{\ast, \hat{P}^\ast}(s)} \\
&\leq \frac{40c_b}{\sigma(1 - \gamma)} \left[ \frac{SC_{\text{rob}}^* \log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)\delta} \right)}{P_{\min}^*N} \right],
\end{aligned} \tag{220} \]

where (i) arises from Cauchy-Schwarz inequality, and the last inequality holds since \( P_{\min}(s, \pi^\ast(s)) \geq P_{\min}^* \) for all \( s \in S \) (see (196)) and the following fact (which has been established in (95)):

\[ \sum_{s \in S} \min \left\{ d_{\ast, \hat{P}^\ast}(s), \frac{1}{3} \right\} \leq 2S. \]

Finally, inserting (220) back into (215), with probability at least \( 1 - 2\delta \), one has

\[ V_{\ast, \pi}(\rho) - V_{\hat{\pi}, \pi}(\rho) \leq \frac{2}{1 - \gamma} \langle d_{\ast, \hat{P}^\ast}, b_{\ast} \rangle \leq \frac{80c_b}{\sigma(1 - \gamma)^2} \left[ \frac{SC_{\text{rob}}^* \log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)\delta} \right)}{P_{\min}^*N} \right], \]

which concludes the proof.

### C.3.1 Proof of Lemma 13

We first note that the second assertion in (202) is the counterpart of (77), which can be verified following the same argument in Appendix B.2.1. For brevity, we omit its proof, and shall focus on verifying (201).
To begin with, we consider the situation when $N(s, a) = 0$. In this case, (201) can be easily verified since

$$
\left| \inf_{P \in \mathcal{U}^r(P_{s,a}^0)} P V - \inf_{P \in \mathcal{U}^r(P_{s,a})} P V \right| \leq \frac{1}{\gamma},
$$

where (i) follows from the fact $\hat{P}_{s,a}^0 = 0$ when $N(s, a) = 0$ (see (42)), and (ii) arises from the assumption $\|V\|_{\infty} \leq \frac{1}{1-\gamma}$. Consequently, in the remainder of the proof, we focus on verifying (201) when $N(s, a) > 0$. Let us first introduce the counterpart of the claim (76) in Lemma 10 as follows.

**Lemma 14.** For all $(s, a) \in S \times A$ with $N(s, a) > 0$, consider any vector $V \in \mathbb{R}^S$ independent of $\hat{P}_{s,a}^0$ obeying $\|V\|_{\infty} \leq \frac{1}{1-\gamma}$. With probability at least $1 - \delta$, one has

$$
\left| \inf_{P \in \mathcal{U}^r(P_{s,a}^0)} P V - \inf_{P \in \mathcal{U}^r(P_{s,a})} P V \right| \leq \frac{c_B}{\sigma(1-\gamma)} \sqrt{\frac{\log(N^2)}{P_{\min}(s,a)N(s,a)}},
$$

**Proof.** The proof follows from the same arguments in Appendix B.2.2, with small modifications to adapt to the infinite-horizon setting; we omit the details for conciseness. \qed

Armed with the above point-wise concentration bound, we are now ready to derive the uniform concentration bound desired as in Lemma 13, counting on a leave-one-out argument divided into the following steps. The crux of the analysis is to construct a set of auxiliary RMDPs, each different from the empirical RMDP only at a single state but possessing crucial statistical independence that facilitates the concentration arguments, which can then be transferred back to the empirical RMDP via a simple triangle inequality.

**Step 1: construction of auxiliary RMDPs with state-absorbing empirical nominal transitions.**

Denote the empirical infinite-horizon robust MDP with the nominal transition kernel $\hat{P}_{s,a}^0$ as $\hat{M}_{rob}$. Then, for each state $s$ and each scalar $u \geq 0$, we can construct an auxiliary robust MDP $\hat{M}_{rob}^{s,u}$ so that it is the same as $\hat{M}_{rob}$ except the properties in state $s$. To be precise, let the nominal transition kernel and reward function of $\hat{M}_{rob}^{s,u}$ be $P^{s,u}$ and $r^{s,u}$, which are given respectively as

$$
P^{s,u}(s' | s, a) = \mathbb{1}(s' = s) \quad \text{for all } (s', a) \in S \times A,
$$

$$
P^{s,u}(\cdot | \bar{s}, a) = \hat{P}_{s,a}^0(\cdot | \bar{s}, a) \quad \text{for all } (\bar{s}, a) \in S \times A \text{ and } \bar{s} \neq s,
$$

and

$$
r^{s,u}(s, a) = u \quad \text{for all } a \in A,
$$

$$
r^{s,u}(\bar{s}, a) = r(\bar{s}, a) \quad \text{for all } (\bar{s}, a) \in S \times A \text{ and } \bar{s} \neq s.
$$

Clearly, state $s$ of the auxiliary $\hat{M}_{rob}^{s,u}$ is absorbing, meaning that the state stays at $s$ once entering it. This removes the randomness of $\hat{P}_{s,a}^0$ for all $a \in A$ in state $s$, a key property we will leverage later.

With the robust MDP $\hat{M}_{rob}^{s,u}$ in hand, we still need to complete the design by defining the corresponding penalty term for all $(\bar{s}, a) \in S \times A$, which is given as follows

$$
b^{s,u}(\bar{s}, a) := \min \left\{ \frac{c_B}{\sigma(1-\gamma)} \sqrt{\frac{\log(\frac{2\gamma}{(1-\gamma)^3})}{P_{\min}(s,a)N(s,a)}}, \frac{4}{N \sigma(1-\gamma)}, \frac{2}{\sigma N} \right\} + \frac{2}{\sigma N} \quad \text{if } N(s,a) > 0,
$$

$$
\text{otherwise},
$$

where $P_{\min}(s,a)$ is defined as the smallest positive state transition probability over the nominal kernel $P^{s,u}(\cdot | \bar{s}, a)$:

$$
\forall (\bar{s}, a) \in S \times A : \ P_{\min}(\bar{s}, a) := \min_{s'} \left\{ P^{s,u}(s' | \bar{s}, a) : P^{s,u}(s' | \bar{s}, a) > 0 \right\}.
$$

50
In view of (223) and (45), it holds that \( P_{\min}^{s,u}(s, a) = \hat{P}_{\min}(s, a) \), and therefore \( b^{\ast,u}(s, a) = b(s, a) \), when \( s \neq s \) for any \( u \geq 0 \). Armed with the above definitions, the pessimistic robust Bellman operator \( \hat{\mathcal{T}}_{s,u}^{\sigma}(Q)(\cdot) \) of the RMDP \( \hat{\mathcal{M}}_{\text{rob}}^{s,u} \) is defined as

\[
\forall(s, a) \in S \times A : \hat{\mathcal{T}}_{s,u}^{\sigma}(Q)(s, a) = \max \left\{ r(s, a) + \gamma \inf_{P \in U^\sigma(P_{s,u}^u)} PV - b^{\ast,u}(s, a), 0 \right\} . \tag{227}
\]

**Step 2: fixed-point equivalence between \( \hat{\mathcal{M}}_{\text{rob}} \) and the auxiliary RMDP \( \hat{\mathcal{M}}_{\text{rob}}^{s,u} \).**

Recall that \( \hat{Q}_{pe}^{s,u} \) is the unique fixed point of \( \hat{\mathcal{T}}_{pe}^{\sigma}(\cdot) \) with the corresponding value \( \hat{V}_{pe}^{s,u} \). We claim that there exists some choice of \( u \) such that the fixed point of \( \hat{\mathcal{T}}_{s,u}^{\sigma}(Q)(\cdot) \) coincides with that of \( \hat{\mathcal{T}}_{pe}^{\sigma}(\cdot) \). In particular, given a state \( s \), we show the following choice of \( u \) suffices:

\[
u^* := (1 - \gamma)\hat{V}_{pe}^{s,u}(s) + \min \left\{ \frac{c_b}{\sigma(1 - \gamma)} \sqrt{\log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)^{2\sigma}} \right)} + \frac{1}{N\sigma(1-\gamma)} + \frac{2}{\sigma N} \right\} \tag{228}
\]

Towards this, we shall break our arguments in two different cases.

- **For state \( s' \neq s \).** In this case, for any \( a \in A \), it can be verified that

\[
\max \left\{ r^{s,u'}(s', a) + \gamma \inf_{P \in U^\sigma(P_{s,u'}^{s,u'})} PV - b^{s,u'}(s', a), 0 \right\} = \hat{\mathcal{T}}_{pe}(\hat{Q}_{pe}^{s,u})(s', a) = \hat{Q}_{pe}^{s,u}(s', a), \tag{229}
\]

where the second line follows from the definitions in (224) and (223) as well as \( b^{s,u'}(s', a) = b(s', a) \) when \( s' \neq s \), the last line arises from the definition of the pessimistic Bellman operator (44), and that \( \hat{Q}_{pe}^{s,u} \) is the fixed point.

- **For state \( s \).** In this case, for any \( u \) and \( a \in A \), observing that \( P_{s,u}^{s,u'}(s' \mid s, a) \) has only one positive entry equal to 1 (cf. (223)), applying (226) yields

\[
P_{\min}^{s,u}(s, a) = 1. \tag{230}
\]

Plugging the above fact into (225) leads to

\[
b^{s,u}(s, a) = \begin{cases} 
\min \left\{ \frac{c_b}{\sigma(1 - \gamma)} \sqrt{\log \left( \frac{2(1+\sigma)N^3S}{(1-\gamma)^{2\sigma}} \right)} + \frac{1}{N\sigma(1-\gamma)} + \frac{2}{\sigma N} \right\} & \text{if } N(s, a) > 0, \\
\frac{1}{1-\gamma} & \text{otherwise}
\end{cases} \tag{231}
\]

for all \( a \in A \). As a result, we have for any \( a \in A \):

\[
\max \left\{ r^{s,u'}(s, a) + \gamma \inf_{P \in U^\sigma(P_{s,u'}^{s,u'})} PV - b^{s,u'}(s, a), 0 \right\} = \max \left\{ u^* + \gamma \hat{V}_{pe}^{s,u}(s) - b^{s,u'}(s, a), 0 \right\} = \max \left\{ (1 - \gamma)\hat{V}_{pe}^{s,u}(s) + \gamma \hat{V}_{pe}^{s,u}(s), 0 \right\} = \hat{V}_{pe}^{s,u}(s), \tag{232}
\]

where the second line follows from the fact that \( P_{s,a}^{s,u'} \) is a singleton distribution at state \( s \), and hence \( \mathcal{U}(P_{s,a}^{s,u'}) = P_{s,a}^{s,u'} \) by the definition of the KL uncertainty set, and the second line follows from plugging in the definition of \( u^* \) in (228) and \( b^{s,u'}(s, a) \) in (231).

51
Summing up the above two cases, we establish that there exists a fixed point \( \hat{Q}^*_{s,u} \) of the operator \( \hat{T}^*_{s,u} (\cdot) \) if we let
\[
\begin{align*}
\hat{Q}^*_{s,u}(s,a) &= \hat{V}^*_{pe}(s) & \text{for all } a \in A, \\
\hat{Q}^*_{s,u}(s',a) &= \hat{Q}_{pe}(s',a) & \text{for all } s' \neq s \text{ and } a \in A.
\end{align*}
\]
(233)

Consequently, we confirm the existence of a fixed point of the operator \( \hat{T}^*_{s,u} (\cdot) \). In addition, its corresponding value function \( \hat{V}^*_{s,u} \) also coincides with \( \hat{V}^*_{pe} \).

**Step 3: building an \( \varepsilon \)-net for all reward values \( u \).** It is easily verified that the reward \( u^* \) obeys
\[
u^* \leq 1 + \min\left\{ \frac{c_b}{\sigma(1-\gamma)} \sqrt{\frac{\log \left( \frac{2(1+\gamma)N^3S}{(1-\gamma)^3} \right)}{P_{\min}^S(s,a)N(s,a)}}, \frac{4}{\sigma N(1-\gamma)}, \frac{1}{1-\gamma} \right\} + \frac{2}{\sigma} \leq \frac{2}{\sigma} + \frac{2}{1-\gamma}.
\]
(234)

As a result, we construct an \( \varepsilon \)-net (Vershynin, 2018) of the line segment within the range \([0, \frac{2}{\sigma} + \frac{2}{1-\gamma}]\) with \( \varepsilon = \frac{1}{\sigma N} \) as follows:
\[
U_{\varepsilon} := \left\{ \frac{i}{\sigma N} | 1 \leq i \leq \left\lfloor \sigma N \left( \frac{2}{\sigma} + \frac{2}{1-\gamma} \right) \right\rfloor \right\}.
\]
(235)

Armed with this covering net \( U_{\varepsilon} \), we can construct an auxiliary robust MDP \( \hat{M}^*_{\text{rob}} \) and its corresponding pessimistic robust Bellman operator for each \( u \in U_{\varepsilon} \) (see Step 1). Following the same arguments in the proof of Lemma 2 (cf. Appendix C.1), for each \( u \in U_{\varepsilon} \), it can be verified that there exists a unique fixed point \( \hat{Q}^*_{s,u} \) of the operator \( \hat{T}^*_{s,u} (\cdot) \), which satisfies \( 0 \leq \hat{Q}^*_{s,u} \leq \frac{1}{1-\gamma} \cdot 1 \). In turn, the corresponding value function also satisfies \( \|\hat{V}^*_{s,u}\|_{\infty} \leq \frac{1}{1-\gamma} \).

In view of the definitions in (223) and (224), for all \( u \in U_{\varepsilon}, \hat{M}^*_{\text{rob}} \) is statistically independent from \( \hat{P}_0 \), which indicates the independence between \( \hat{V}^*_{s,u} \) and \( \hat{P}_0 \). This makes it possible to invoke Lemma 14, and taking the union bound over all samples \( N \) and \( u \in U_{\varepsilon} \) give that, with probability at least \( 1 - \delta \),
\[
\inf_{P \in U_{\varepsilon}(\hat{P}_0^S)} \mathcal{P} \hat{V}^*_{s,u} - \inf_{P \in U_{\varepsilon}(\hat{P}_0^S)} \mathcal{P} \hat{V}^*_{s,u} \leq \frac{c_b}{\sigma(1-\gamma)} \sqrt{\frac{\log \left( \frac{2(1+\gamma)N^3S}{(1-\gamma)^3} \right)}{P_{\min}^S(s,a)N(s,a)}}
\]
(236)

hold simultaneously for all \((s,a,u) \in S \times A \times U_{\varepsilon}\) with \( N(s,a) > 0 \).

**Step 4: a covering argument.** Recalling that \( u^* \in \left[ 0, \frac{2}{\sigma} + \frac{2}{1-\gamma} \right] \) (see (234)), we can always find some \( \bar{u} \in U_{\varepsilon} \) such that \( |\bar{u} - u^*| \leq \frac{1}{\sigma N} \). Consequently, plugging in the operator in (227) yields
\[
\forall Q \in \mathbb{R}^{S,A} : \left\| \hat{T}^*_{s,u}(Q) - \hat{T}^*_{s,u}(Q) \right\|_{\infty} \leq |\bar{u} - u^*| \leq \frac{1}{\sigma N},
\]
(237)

where (i) holds by \( b^{s,\bar{u}}(s,a) = b^{s,u^*}(s,a) \) for \( s \) (see (231)) and \( b^{s,\bar{u}}(s',a) = b^{s,u^*}(s',a) = b(s',a) \) for all \( s' \neq s \).

With this in mind, we observe that the fixed points of \( \hat{T}^*_{s,u} (\cdot) \) and \( \hat{T}^*_{s,u} (\cdot) \) obey
\[
\left\| \hat{Q}^*_{s,u} - \hat{Q}^*_{s,u} \right\| = \left\| \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) - \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) \right\|_{\infty} \leq \left\| \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) - \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) \right\|_{\infty} + \left\| \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) - \hat{T}^*_{s,u}(\hat{Q}^*_{s,u}) \right\|_{\infty} \leq \gamma \left\| \hat{Q}^*_{s,u} - \hat{Q}^*_{s,u} \right\|_{\infty} + \frac{1}{\sigma N},
\]
(238)

which directly indicates that
\[
\left\| \hat{Q}^*_{s,u} - \hat{Q}^*_{s,u} \right\| \leq \frac{1}{(1-\gamma)\sigma N}
\]
(239)
and
\[ \| \hat{V}_{s,u}^{*,\sigma} - \hat{V}_{s,u}^{*,\sigma} \|_{\infty} \leq \| \hat{Q}_{s,u}^{*,\sigma} - \hat{Q}_{s,u}^{*,\sigma} \|_{\infty} \leq \frac{1}{(1 - \gamma)\sigma N}. \] (240)

Armed with the above facts, invoking the identity \( \hat{V}_{pe}^{*,\sigma} = \hat{V}_{s,u}^{*,\sigma} \) established in Step 2 gives
\[
\begin{align*}
&\left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{pe}^{*,\sigma} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} \right| \\
&\leq \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} \right| \\
&\quad + \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} \right| \\
&\quad + \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V}_{s,u}^{*,\sigma} \right| \\
&\leq \frac{c_b}{\sigma(1 - \gamma)\sqrt{\log \left( \frac{2(1 + \alpha)NS}{(1 - \gamma)\delta} \right)}} \frac{2}{N\sigma(1 - \gamma)}, \quad (241)
\end{align*}
\]

where (i) holds by applying the triangle inequality, (ii) arises from (240) and the basic fact that infimum operator is a 1-contraction w.r.t. \( \| \cdot \|_{\infty} \), and the final inequality follows from (236).

**Step 5: finishing up.** Now we are positioned to finish up the proof. For all vector \( \hat{V} \) obeying \( \| \hat{V} - \hat{V}_{pe}^{*,\sigma} \|_{\infty} \leq \frac{1}{\sigma N} \) and \( \| \hat{V} \|_{\infty} \leq \frac{1}{1 - \gamma} \), we apply the triangle inequality and invoke (241) to reach
\[
\begin{align*}
&\left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} \right| \\
&\leq \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} \right| \\
&\quad + \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} \right| \\
&\quad + \left| \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} \right| \\
&\leq \frac{c_b}{\sigma(1 - \gamma)\sqrt{\log \left( \frac{2(1 + \alpha)NS}{(1 - \gamma)\delta} \right)}} \frac{2}{N\sigma(1 - \gamma)}, \quad (242)
\end{align*}
\]

Finally, we complete the proof by verifying that
\[ \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} - \inf_{P \in \mathcal{U}^*(P_{s,a}^0)} \mathcal{P}\hat{V} \leq \| \hat{V} \|_{\infty} \leq \frac{1}{1 - \gamma}. \] (243)

**C.3.2 Proof of (198)**

For all \((s,a) \in \mathcal{C}^b\), one has
\[ N\mathcal{C}^b(s,a) \geq \frac{c_1 d^b(s,a) \log(NS/\delta)}{d_{\min}^b P_{\min}^b} \geq \frac{c_1 \log(NS/\delta)}{P_{\min}^b} \geq \frac{c_1 \log(NS/\delta)}{P_{\min}^b}, \quad (244) \]

where (i) follows from the condition (56), (ii) arises from the definition that \( d_{\min}^b \leq d^b(s,a) \) for all \((s,a) \in \mathcal{C}^b\), and (iii) follows from the definition in (196). In particular, when \( c_1 \) is large enough, one has \( \frac{\delta}{4} \log \frac{NS}{\delta} < N_d(s,a) \). To continue, we recall a key property of \( N(s,a) \) (cf. (41)) in the following lemma.
Lemma 15 ((Li et al., 2022, Lemma 7)). Fix $\delta \in (0, 1)$. With probability at least $1 - \delta$, the quantities \( \{N(s,a)\} \) in (41) obey

$$
\max \left\{ N(s,a), \frac{2}{3} \log \frac{NS}{\delta} \right\} \geq \frac{Nd(s,a)}{12}
$$

simultaneously for all \((s,a)\in S\times A\).

Consequently, Lemma 15 tells us that with probability at least $1 - \delta$,

$$
N(s,a) \geq \frac{Nd(s,a)}{12} \geq c_1 \log(NS/\delta) \geq c_1 \log(\frac{2NS}{\delta} \log(1 - P_{\min}(s,a)))
$$

as long as $c_1$ is large enough. Last but not least, taking the basic fact $x \leq -\log(1 - x)$ for all $x \in [0, 1]$, the last inequality of (198) can be verified by

$$
c_1 \log(NS/\delta) \geq \frac{\log 2NS}{\log(1 - P_{\min}(s,a))}.
$$

C.4 Proof of Theorem 4

Similar to the finite-horizon case, we shall first construct some hard discounted infinite-horizon RMDP instances and then characterize the sample complexity requirements over these instances.

C.4.1 Construction of hard problem instances

Construction of a collection of hard MDPs. Suppose there are two MDPs \( \mathcal{M}_\phi = (S,A,P^\phi,r,\gamma) \mid \phi = \{0, 1\} \).

Here, $\gamma$ is the discount parameter, $S = \{0, 1, \ldots, S - 1\}$ is the state space, and $A = \{0, 1\}$ is the action space. The transition kernel $P^\phi$ of either constructed MDP $\mathcal{M}_\phi$ is defined as

$$
P^\phi(s'|s,a) = \begin{cases} 
p \mathbb{1}(s' = 2) + (1 - p) \mathbb{1}(s' = 1) & \text{if } (s,a) = (0, \phi) 
q \mathbb{1}(s' = 2) + (1 - q) \mathbb{1}(s' = 1) & \text{if } (s,a) = (0, 1 - \phi) 
\mathbb{1}(s' = s) & \text{if } s = 1 \text{ or } s = 2 
q \mathbb{1}(s' = s) + (1 - q) \mathbb{1}(s' = 1) & \text{if } s > 2
\end{cases}
$$

where $p$ and $q$ are set as

$$
p = 1 - \alpha \quad \text{and} \quad q = 1 - \alpha - \Delta
$$

for some $\gamma$, $\alpha$ and $\Delta$ obeying

$$
0 < \alpha \leq 1 - \gamma \leq 1/(2e^8) \leq \frac{1}{2} \quad \text{and} \quad \Delta \leq \frac{\alpha}{2}.
$$

Here, $\alpha$ and $\Delta$ are some values that will be introduced later. Consequently, applying (249) directly leads to

$$
1 \geq p \geq q \geq \gamma \geq \frac{1}{2}.
$$

Note that state 1 and 2 are absorbing states. In addition, if the initial distribution is supported on states \{0, 1, 2\}, the MDP will always stay in the state \{1, 2\} after the first transition.

Finally, we define the reward function as

$$
r(s,a) = \begin{cases} 
1 & \text{if } s = 0 \text{ or } s = 2 
0 & \text{otherwise}
\end{cases}
$$
Construction of the history/batch dataset. Define a useful state distribution (only supported on the state subset \{0, 1, 2\}) as
\[
\mu(s) = \frac{1}{CS} \mathbb{I}(s = 0) + \frac{1}{CS} \mathbb{I}(s = 2) + \left(1 - \frac{2}{CS}\right) \mathbb{I}(s = 1),
\]
(253)
where \(C > 0\) is some constant that determines the robust concentrability coefficient \(C^*_\text{rob}\) (which will be made clear soon) and obeys
\[
\frac{1}{CS} \leq \frac{1}{4}.
\]
(254)

A batch dataset—consists of \(N\) i.i.d samples \(\{(s_i, a_i, s'_i)\}_{1 \leq i \leq N}\)—is generated over the nominal environment \(M_\phi\) according to (38), with the behavior distribution chosen to be:
\[
\forall (s, a) \in \mathcal{S} \times \mathcal{A}: \quad d^\phi(s, a) = \frac{\mu(s)}{2}.
\]
(255)

Additionally, we choose the following initial state distribution:
\[
\rho(s) = \begin{cases} 1, & \text{if } s = 0 \\ 0, & \text{otherwise} \end{cases}.
\]
(256)

Uncertainty set of the transition kernels. We next describe the radius \(\sigma\) of the uncertainty set in our construction of the robust MDPs, along with some useful properties, which are similar to the finite-horizon case. To begin with, with slight abuse of notation, we introduce an important constant \(\beta\) defined as
\[
\beta := \frac{1}{2} \log \frac{1}{\alpha + \Delta} \geq 4.
\]
(257)
The perturbed transition kernels in \(M_\phi\) is limited to the following uncertainty set
\[
\mathcal{U}^\sigma(P_\phi) := \otimes \mathcal{U}^\sigma(P_{s,a}^\phi), \quad \mathcal{U}^\sigma(P_{s,a}^\phi) := \{P_{s,a} \in \Delta(\mathcal{S}) : \text{KL}(P_{s,a} \parallel P_{s,a}^\phi) \leq \sigma\},
\]
(258)
where \(P_{s,a}^\phi := P_\phi(\cdot | s, a) \in [0, 1]^{1 \times S}\). Moreover, the radius of the uncertainty set \(\sigma\) obeys
\[
\left(1 - \frac{3}{\beta}\right) \log \frac{1}{\alpha + \Delta} \leq \sigma \leq \left(1 - \frac{2}{\beta}\right) \log \frac{1}{\alpha + \Delta}.
\]
(259)

For any \((s, a, s') \in \mathcal{S} \times \mathcal{A} \times \mathcal{S}\), we denote the infimum entry of the perturbed transition kernel \(P_{s,a} \in \mathcal{U}^\sigma(P_{s,a}^\phi)\) moving to the next state \(s'\) as
\[
P_{s,a}^\phi(s' | s, a) := \inf_{P_{s,a} \in \mathcal{U}^\sigma(P_{s,a}^\phi)} P(s' | s, a).
\]
(260)

As shall be seen, the transition from state 0 to state 2 plays an important role in the analysis, for convenience, we denote
\[
p := P_\phi(2 | 0, \phi), \quad q := P_\phi(2 | 0, 1 - \phi).
\]
(261)

With these definitions in place, we summarize some useful properties of the uncertainty set in the following lemma, which parallels Lemma 11 in the finite-horizon case.

Lemma 16. Suppose \(\beta\) satisfies (257) and the uncertainty level \(\sigma\) satisfies (259). The perturbed transition kernels obey
\[
p \geq q \geq \frac{1}{\beta}.
\]
(262)

Proof. The proof follows from the same arguments as Appendix B.3.4 by replacing \(H\) with \(\frac{1}{1-\gamma}\); we omit the details for brevity.\[\square\]
Value functions and optimal policies. Now we are positioned to derive the corresponding robust value functions and identify the optimal policies. For any MDP $\mathcal{M}_\phi$ with the above uncertainty set, denote $\pi^*_\phi$ as the optimal policy. In addition, we denote the robust value function of any policy $\pi$ (resp. the optimal policy $\pi^*_\phi$) as $V_{\phi}^{*,\sigma}$ (resp. $V_{\phi}^{*,\sigma}$). Then, we introduce the following lemma which describes some important properties of the robust value functions and optimal policies.

**Lemma 17.** For any $\phi \in \{0, 1\}$ and any policy $\pi$, one has

$$V_{\phi}^{*,\sigma}(0) = 1 + \frac{\gamma}{1 - \gamma} z_{\phi}^\pi,$$

(263)

where $z_{\phi}^\pi$ is defined as

$$z_{\phi}^\pi := p(\phi \mid 0) + q(1 - \phi \mid 0).$$

(264)

In addition, the optimal value functions and the optimal policies obey

$$V_{\phi}^{*,\sigma}(0) = 1 + \frac{\gamma}{1 - \gamma} p, \quad V_{\phi}^{*,\sigma}(2) = \frac{1}{1 - \gamma}, \quad V_{\phi}^{*,\sigma}(s) = 0 \quad \text{for } s = 1 \text{ or } s > 2,$$

(265a)

$$\pi^*_\phi(\phi \mid s) = 1, \quad \text{for } s \in S.$$  

(265b)

Moreover, choosing $S \geq 2\beta$, the robust single-policy clipped concentrability coefficient $C^*_\text{rob}$ obeys

$$C^*_\text{rob} = 2C.$$  

(266)

**Proof.** See Appendix C.4.3. \qed

C.4.2 Establishing the minimax lower bound

Now we are positioned to provide the sample complexity lower bound. In view of Lemma 17, the smallest positive state transition probability of the optimal policy $\pi^*_\phi$ under any nominal transition kernel $P^\phi$ with $\phi \in \{0, 1\}$ satisfies:

$$P^*_\text{min} := \min_{s,s'} \left\{ P^\phi(s' \mid s, \pi^*_\phi(s)) : P^\phi(s' \mid s, \pi^*_\phi(s)) > 0 \right\} = P^\phi(1|0, \phi) = 1 - p.$$  

(267)

Our goal is to control the quantity w.r.t. any policy estimator $\hat{\pi}$ based on the batch dataset and the chosen initial distribution $\rho$ in (256), which gives

$$V_{\phi}^{*,\sigma}(\rho) - V_{\phi}^{*,\sigma}(\rho) = V_{\phi}^{*,\sigma}(0) - V_{\phi}^{*,\sigma}(0).$$  

(268)

Towards this, we first introduce the following lemma, which parallels the claim in (141)-(142) in the finite-horizon case.

**Lemma 18.** Given $\epsilon \leq \frac{1}{384e^{\sigma} (1 - \gamma) \log \left( \frac{1}{\alpha} \right)} \leq \frac{1}{384e^{\sigma} (1 - \gamma) \log \left( \frac{1}{\alpha - \gamma} \right)}$, choosing $\Delta = 128e^{\sigma} (1 - q) \epsilon (1 - \gamma) \leq 128e^{\sigma} (\alpha + \Delta) \epsilon \log \left( \frac{1 - \gamma}{\alpha - \gamma} \right) \leq \frac{\epsilon}{2}$, one has for any policy $\hat{\pi}$,

$$V_{\phi}^{*,\sigma}(0) - V_{\phi}^{*,\sigma}(0) \geq 2\epsilon (1 - \hat{\pi}(\phi \mid 0)).$$

**Proof.** This lemma follows from the same arguments as Appendix B.3.6 except replacing $H$ with $\frac{1}{1 - \gamma}$ under the additional condition $\gamma \geq \frac{1}{2}$; we omit the details for brevity. \qed

Armed with this lemma, following the same arguments in Appendix B.3.2, we can complete the proof by observing that: let $c_1$ be some sufficient large constant, as long as the sample size is beneath

$$N \leq \frac{SC^*_\text{rob} \log 2}{4c_1 P^*_\text{min} \sigma^2 (1 - \gamma)^2 \epsilon^2},$$

(269)

then we necessarily have

$$\inf_{\hat{\pi}} \max_{\phi \in \{0, 1\}} \mathbb{P}_\phi \left\{ V_{\phi}^{*,\sigma}(\rho) - V_{\phi}^{*,\sigma}(\rho) \geq \epsilon \right\} \geq \frac{1}{8},$$

(270)

where $\mathbb{P}_\phi$ denote the probability conditioned on that the MDP is $\mathcal{M}_\phi$. We omit the details for brevity and complete the proof.
C.4.3 Proof of Lemma 17

For any $\mathcal{M}_\phi$ with $\phi \in \{0, 1\}$, due to state absorbing, the uncertainty set becomes a singleton containing the nominal distribution at state $s = 1$ and $s = 2$. It is easily observed that for any policy $\pi$, the robust value functions at state $s = 1$ and $s = 2$ obey

$$V_{\phi}^{\pi, \sigma}(1) = \sum_{t=0}^{\infty} \gamma^t \cdot 0 = 0,$$

$$(271a)$$

$$V_{\phi}^{\pi, \sigma}(2) = \sum_{t=0}^{\infty} \gamma^t \cdot 1 = \frac{1}{1 - \gamma},$$

$$(271b)$$

since $r(1, a) = 0$ and $r(2, a) = 1$. In addition, for state $s > 2$, the perturbed transition kernel is supported on itself and state 1, both of which receive a reward of 0 by design (252), leading to

$$V_{\phi}^{\pi, \sigma}(s) = \sum_{t=0}^{\infty} \gamma^t \cdot 0 = 0, \quad \text{for } s > 2.$$  

$$(271c)$$

Moving onto the remaining states, the robust value function of state 0 satisfies

$$V_{\phi}^{\pi, \sigma}(0) = \mathbb{E}_{a \sim \pi(\cdot | 0)} \left[ r(0, a) + \gamma \inf_{P \in \mathcal{U}(P_{\phi}^0)} \mathcal{P} V_{\phi}^{\pi, \sigma} \right]$$

$$(i) = 1 + \gamma \pi(\phi | 0) \inf_{P \in \mathcal{U}(P_{\phi}^0)} \mathcal{P} V_{\phi}^{\pi, \sigma} + \gamma \pi(1 - \phi | 0) \inf_{P \in \mathcal{U}(P_{\phi}^1)} \mathcal{P} V_{\phi}^{\pi, \sigma}$$

$$(ii) = 1 + \gamma V_{\phi}^{\pi, \sigma}(1) + \gamma z_{\phi}^\pi [V_{\phi}^{\pi, \sigma}(2) - V_{\phi}^{\pi, \sigma}(1)]$$

$$(iii) = 1 + \frac{\gamma}{1 - \gamma} z_{\phi}^\pi,$$

$$(272)$$

where (i) holds by the reward function defined in (252). To see (ii), note that (271) indicates $V_{\phi}^{\pi, \sigma}(2) \geq V_{\phi}^{\pi, \sigma}(1)$, so that the infimum is obtained by picking the smallest possible mass on the transition to state 2, provided by the definition in (261). Last but not least, (iii) follows by plugging in the definition of $z_{\phi}^\pi$ in (264), and the last identity is due to (271). Consequently, taking $\pi = \pi_{\phi}^\star$, we directly arrive at

$$V_{\phi}^{\pi_{\phi}^\star, \sigma}(0) = 1 + \frac{\gamma}{1 - \gamma} z_{\phi}^\pi.$$  

$$(273)$$

Observing that the function $z_{\frac{1}{1 - \gamma}}$ is increasing in $z$ and $z_{\phi}^\pi$ is also increasing in $\pi(\phi | 0)$ (see the fact $p \geq q$ in (262)), the optimal policy in state 0 thus obeys

$$\pi_{\phi}^\star(\phi | 0) = 1.$$  

$$(274)$$

Finally, plugging the above fact back into (264) leads to

$$z_{\phi}^\star := z_{\phi}^\pi = p \pi_{\phi}^\star(\phi | 0) + q \pi_{\phi}^\star(1 - \phi | 0) = p,$$

$$(275)$$

which combined with (273) yields

$$V_{\phi}^{\pi_{\phi}^\star, \sigma}(0) = 1 + \frac{\gamma}{1 - \gamma} p.$$  

$$(276)$$

Regarding the optimal policy for the remaining states $s > 0$, since the action does not influence the state transition, without loss of generality, we choose the optimal policy to obey

$$\forall s > 0: \ \pi_{\phi}^\star(\phi | s) = 1.$$  

$$(277)$$
**Proof of (266).** To begin with, for any MDP $\mathcal{M}_\phi$ with $\phi \in \{0, 1\}$, recall the definition of $C^\ast_{\text{rob}}$ as

$$C^\ast_{\text{rob}} = \max_{(s,a,P) \in S \times A \times U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(s,a), \frac{1}{S}}{d^B(s,a)} \right\}.$$  

(278)

Given $\pi^\ast_\phi(s | s) = 1$ for all $s \in S$ and the initial distribution $\rho(0) = 1$, for any $P \in U^\sigma(P^\phi)$, we arrive at

$$d^\ast,P(0,0) = (1 - \gamma)\rho(0)\pi^\ast_\phi(0 | 0) = (1 - \gamma),$$  

(279)

which holds due to that the agent transits from state 0 to other states at the first step and then will never go back to state 0. In addition, one has for any $P \in U^\sigma(P^\phi)$,

$$d^\ast,P(2,0) = (1 - \gamma)P(2 | 0, \phi) \sum_{t=1}^{\infty} \gamma^t \left( P(2 | 2, \phi) \right)^t = (1 - \gamma)P(2 | 0, \phi) \sum_{t=1}^{\infty} \gamma^t \geq \gamma \frac{1}{2}$,$$

(280)

where (i) holds by (261) and the final inequality follows from (262) and $\gamma \geq 1/2$. Armed with the above facts, we observe that

$$\max_{(s,a,P) \in S \times A \times U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(s,a), \frac{1}{S}}{d^B(s,a)} \right\} = \max_{s \in \{0, 1, 2\}, P \in U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(s,\phi), \frac{1}{S}}{d^B(s,\phi)} \right\}$$  

(281)

which follows from the properties of the optimal policy in (277) and consequently $d^\ast,P(s) = d^\ast,P(s,\phi) = 0$ for all $s > 2$ and all $P \in U^\sigma(P^\phi)$.

To continue, we control the term in states $\{0, 1, 2\}$ separately:

$$\max_{P \in U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(2,\phi), \frac{1}{S}}{d^B(2,\phi)} \right\} = \left( \frac{1}{S} \right) \frac{d^B(2,\phi)}{d^B(2,\phi)} = 2C,$$

(282a)

$$\max_{P \in U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(0,\phi), \frac{1}{S}}{d^B(0,\phi)} \right\} \leq \frac{1}{S} \frac{d^B(0,\phi)}{d^B(0,\phi)} = \frac{2}{S\mu(0)} = 2C,$$

(282b)

$$\max_{P \in U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(1,\phi), \frac{1}{S}}{d^B(1,\phi)} \right\} \leq \frac{1}{S} \frac{d^B(1,\phi)}{d^B(1,\phi)} = \frac{2}{S \left( 1 - \frac{2}{c^2} \right)} \leq \frac{4}{S} \leq C,$$

(282c)

where (i) holds by (280) and $S \geq 2\beta$, (ii), (iii) and (iv) follow from the definitions in (255) and (253), (v) and (vi) arise from the assumption in (254). Plugging the above results back into (281) directly completes the proof of

$$C^\ast_{\text{rob}} = \max_{(s,a,P) \in S \times A \times U^\ast(P^\phi)} \min \left\{ \frac{d^\ast,P(s,a), \frac{1}{S}}{d^B(s,a)} \right\} = 2C.$$
