Potassium iodide, but not potassium iodate, as a potential protective agent against oxidative damage to membrane lipids in porcine thyroid

Magdalena Milczarek¹, Jan Stepniak¹, Andrzej Lewinski²,³ and Małgorzata Karbownik-Lewinska¹,³*

Abstract

Background: Fenton reaction ($\text{Fe}^{2+} + \text{H}_2\text{O}_2 \rightarrow \text{Fe}^{3+} + \cdot\text{OH} + \cdot\text{OH}^{-}$) is of special significance in the thyroid gland, as both its substrates, i.e. $\text{H}_2\text{O}_2$ and $\text{Fe}^{2+}$, are required for thyroid hormone synthesis. Also iodine, an essential element supplied by the diet, is indispensable for thyroid hormone synthesis. It is well known that iodine affects red-ox balance. One of the most frequently examined oxidative processes is lipid peroxidation (LPO), which results from oxidative damage to membrane lipids. Fenton reaction is used to experimentally induce lipid peroxidation. The aim of the study was to evaluate effects of iodine, used as potassium iodide (KI) or potassium iodate (KIO₃), on lipid peroxidation in porcine thyroid homogenates under basal conditions and in the presence of Fenton reaction substrates.

Methods: Porcine thyroid homogenates were incubated in the presence of either KI (0.00005–500 mM) or KIO₃ (0.00005–200 mM), without or with addition of FeSO₄ (30 µM) + H₂O₂ (0.5 mM). Concentration of malondialdehyde + 4-hydroxyalkenals (MDA + 4-HDA) was measured spectrophotometrically, as an index of lipid peroxidation.

Results: Potassium iodide, only when used in the highest concentrations ($\geq 50$ mM), increased lipid peroxidation in concentration-dependent manner. In the middle range of concentrations (5.0; 10; 25; 50 and 100 mM) KI reduced Fenton reaction-induced lipid peroxidation, with the strongest protective effect observed for the concentration of 25 mM. Potassium iodate increased lipid peroxidation in concentrations $\geq 2.5$ mM. The damaging effect of KIO₃ increased gradually from the concentration of 2.5 mM to 10 mM. The strongest damaging effect was observed at the KIO₃ concentration of 10 mM, corresponding to physiological iodine concentration in the thyroid. Potassium iodate in concentrations of 5–200 mM enhanced Fenton reaction-induced lipid peroxidation with the strongest damaging effect found again for the concentration of 10 mM.

Conclusions: Potassium iodide, used in doses generally recommended in iodide prophylaxis, may prevent oxidative damage to membrane lipids in this gland. Toxic effects of iodide overload may result from its prooxidative action. Potassium iodate does not possess any direct beneficial effects on oxidative damage to membrane lipids in the thyroid, which constitutes an additional argument against its utility in iodine prophylaxis.

Keywords: Potassium iodide, Potassium iodate, Thyroid, Lipid peroxidation, Ferrous ion, Hydrogen peroxide
Background

Iodine, an essential trace element, is indispensable for thyroid hormone synthesis in humans and animals [1]. The only natural source of iodine is the diet. However, in numerous areas in the world iodine supply from natural sources is inadequate, resulting in iodine deficiency disorders (IDD) [2,3]. Precisely elaborated programs of iodine prophylaxis were introduced in different countries to prevent IDD [4]. These programs are mainly based on salt iodization with the use of either potassium iodide (KI) or potassium iodate (KIO3).

These two compounds are characterised by different chemical properties and some differences in potential toxicity/safety. Iodate is more stable, as iodide is readily oxidized to iodine and lost by evaporation [5]. Whereas reliable methods are validated for quantifying KIO3 salt content, further validation is required for countries that use KI in salt iodization programs [6]. All other differences between KIO3 and KI suggest the superiority of the latter over the former. First, human iodine bioavailability from KI is higher than from KIO3 [7,8]. Second, in biofortification of the former. First, human iodine bioavailability from KI is [11] did even question the use of KIO3 instead of KI in iodization with the use of either potassium iodide (KI) or potassium iodate (KIO3). Additionally, KIO3 is more effective than KIO3 [9,10].

In turn, according to some health authorities, the safety of KIO3 to humans and animals is not completely documented and in 2002 the French Agency for Food Safety [11] did even question the use of KIO3 instead of KI in iodine prophylaxis. Therefore, several experimental studies have been performed to clarify this issue. For example, it has been shown in experimental studies that KIO3 does not reveal genotoxic effects [12]. Also comparative studies of the oxidative properties of iodate and other halogenate salts, such as bromate and chlorate, have shown that iodate would be of low, if any, genotoxic potential [13]. It is worth mentioning that both, KI and KIO3, reveal similar effectiveness as blockers of radiiodine uptake by the thyroid in rats [14].

Nevertheless, according to similar effectiveness in iodine prophylaxis, both KI and KIO3 were initially proved to be used for fortifying salt by the Joint WHO/FAO Expert Committee on Food Additives and Contaminants [15] and they are, along with other iodine salts, still admitted to be added to foods, including food supplements [16].

It is well known that iodine affects red-ox balance [17]. It is especially known for its excellent antioxidative properties in physiological conditions [18,19]. However, prooxidative effects of iodine were also demonstrated in experimental models. For example, in studies in vivo, iodine – given as iodide – expectedly increased MDA level in the rat thyroid and liver [20], or it increased Schiff’s bases in rat lung and liver [21] and – when given as KIO3 – in mice liver [22]. The latter change was accompanied by the increased activities of antioxidative enzymes, such as glutathione peroxidase and superoxide dismutase, but only after longer time (3 months) of iodine exposure [22]. Thus, the balance between anti- and prooxidative effects of iodine depends on different factors, such as iodine dose/concentration or the time of action.

However, anti- or prooxidative effects of iodine on the thyroid gland with relation to iodine source, i.e. a chemical compound containing iodine, have never been examined in vitro, thus under conditions reflecting direct effects of these compounds on thyroid follicular cells.

Fenton reaction (Fe2+ + H2O2 → Fe3+ + ‘OH + OH‘), being the basic reaction of oxidative stress, is of special significance in the thyroid gland, as both its substrates, i.e. H2O2 and Fe2+, are required for thyroid hormone synthesis [23]. One of the most frequently examined oxidative processes is lipid peroxidation (LPO), which results from oxidative damage to membrane lipids. Bivalent iron (Fe2+) and H2O2, which initiate Fenton reaction, have been frequently used to experimentally induce lipid peroxidation in different tissues [24–29], the thyroid gland included [30,31]. Also oxidative damage to nuclear and mitochondrial DNA has been induced by Fenton reaction substrates [32].

The aim of the study was to evaluate effects of iodine, used as potassium iodide (KI) or potassium iodate (KIO3), on lipid peroxidation in porcine thyroid homogenates under basal conditions and in the presence of Fenton reaction substrates.

Preliminary results of the study were presented (as a poster presentation) during International and European Congress of Endocrinology in 2012 [33].

Methods

Ethical approval

The procedures, used in the study, were approved by the Ethics Committee of the Medical University of Lodz, Poland.

Chemicals

Potassium iodide (KI), potassium iodate (KIO3), ferrous sulfate (FeSO4) and hydrogen peroxide (H2O2) were purchased from Sigma (St. Louis, MO). The ALDetect Lipid Peroxidation Assay Kit was obtained from Enzo Life Sciences, Inc. (Zandhoven, Belgium). MilliQ-purified H2O was used for preparing all solutions. All the used chemicals were of analytical grade and came from commercial sources.

Animals

Porcine thyroids were collected from forty five (45) animals at a slaughter-house, frozen on solid CO2, and stored at -80°C until assay. Each experiment was repeated three to five times. Therefore, three to five tissue pools were prepared, with nine (9) thyroid glands used for each homogenate pool.
Assay of lipid peroxidation

Thyroid tissue was homogenized in ice cold 20 mM Tris-HCl buffer (pH = 7.4) (10%, w/v), and then incubated for 30 min at 37°C in the presence of examined substances. Porcine thyroid homogenates were incubated in the presence of either KI (500; 250; 100; 50; 25; 10; 5.0; 2.5; 1.0; 0.5; 0.25; 0.1; 0.05; 0.025; 0.01; 0.005; 0.0025; 0.001; 0.0005; 0.00025 mM) or KIO₃ (200; 150; 100; 50; 25; 10; 5.0; 2.5; 1.0; 0.5; 0.25; 0.1; 0.05; 0.025; 0.01; 0.005; 0.0025; 0.001; 0.0005 mM) or KIO₃ (200; 150; 100; 50; 25; 10; 5.0; 2.5; 1.0; 0.5; 0.25; 0.1; 0.05; 0.025; 0.01; 0.005; 0.0025; 0.001; 0.0005 mM) without or with addition of Fenton reaction substrates, i.e. FeSO₄ (300.00025; 0.0001; 0.00005 mM) or H₂O₂ (0.5 mM), or with addition of FeSO₄ (30 μM) only. According to different solubility of KI and KIO₃, different highest concentrations of these compounds were used in the study. Eight (8) separate experiments were performed, as it is specified in the Results section. The reactions were stopped by cooling the samples on ice. Each experiment was run in duplicate and repeated three to five times.

Measurement of lipid peroxidation products

The concentrations of malondialdehyde + 4-hydroxyalkenals (MDA + 4-HDA), as an index of lipid peroxidation, were measured in thyroid homogenates, with the ALDetect Lipid Peroxidation Assay Kit. The homogenates were centrifuged at 3,000 x g for 10 min at 4°C. After obtaining supernatant, each experiment was carried out in duplicate. The supernatant (200 μl) was mixed with 650 μl of a methanol: acetonitrile (1:3, v/v) solution, containing a chromogenic reagent, N-methyl-2-phenylindole, and vortexed. Following the addition of 150 μl of methanesulfonic acid (15.4 M), the incubation was carried out at 45°C for 40 min. The reaction between MDA + 4-HDA and N-methyl-2-phenylindole yields a chromophore, which is spectrophotometrically measured at the absorbance of 586 nm, using a solution of 10 mM 4-hydroxynonenal as the standard. The level of lipid peroxidation is expressed as the amount of MDA + 4-HDA (nmol) per mg protein. Protein was measured, using Bradford’s method [34], with bovine albumin as the standard.

Statistical analyses

Results are expressed as means ± SE. The data were statistically analyzed, using a one-way analysis of variance (ANOVA), followed by the Student-Neuman-Keuls’ test. The level of p < 0.05 was accepted as statistically significant.

Results

Two examined substances, i.e. KI and KIO₃, did not reveal the same effects on oxidative damage to membrane lipids in porcine thyroid homogenates, both under basal conditions and in the presence of Fenton reaction substrates. Potassium iodide, when used in the highest concentrations (≥50 mM), did increase lipid peroxidation in concentration-dependent manner. In turn, KI in concentrations ≤25 mM did not affect lipid peroxidation (Figure 1).

When KI was used together with Fe²⁺+H₂O₂, the following results were obtained. Potassium iodide used in the middle range of concentrations (5.0; 10; 25; 50 and 100 mM) reduced Fenton reaction-induced lipid peroxidation, with the strongest protective effect observed for the concentration of 25 mM, which completely prevented experimentally-induced lipid peroxidation (Figure 2). Interestingly, KI either in higher (≥250 mM) or lower (≤2.5 mM) concentrations did not affect significantly Fenton reaction-induced lipid peroxidation, which means that the level of lipid peroxidation in the presence of KI (≥250 mM or ≤2.5 mM) plus Fe²⁺+H₂O₂ was the same as in the presence of Fe²⁺+H₂O₂ only (Figure 2).

Subsequently, to compare prooxidative effects of KI alone to prooxidative effects of KI plus Fenton reaction substrates, the separate experiment was performed, in which thyroid homogenates were incubated in the presence of KI (in concentrations of 0.25-500 mM) alone or together with Fe²⁺+H₂O₂ (Figure 3). The level of lipid peroxidation was significantly higher when KI (in concentrations ≤100 mM) was used together with Fe²⁺+H₂O₂. However, KI did not enhance Fenton reaction-induced lipid peroxidation (Figure 3), which is in agreement with results shown in Figure 2.

In our earlier study [31], Fe²⁺ used alone (i.e. as only one of Fenton reaction substrates), in opposite to H₂O₂,
induced lipid peroxidation in thyroid homogenates. Therefore, in the present study we have performed the additional experiment with use of KI (in concentrations of 0.25–500 mM) alone or together with Fe^{2+} (Figure 4). No significant differences in lipid peroxidation were found for respective concentrations of KI in the presence or in the absence of Fe^{2+} (Figure 4).

In the opposite to KI, KIO_{3} revealed, depending on the concentration or the presence/absence of Fe^{2+}+H_{2}O_{2}, either no protective effect at all or even strong pro-oxidative action (Figures 5 and 6). When KIO_{3} was used alone, it did increase lipid peroxidation in concentrations ≥2.5 mM (Figure 5). The damaging effect of KIO_{3} increased gradually from the concentration of 2.5 mM to 10 mM and, then, it decreased again gradually, however still being significantly stronger at the highest used KIO_{3} concentration (200 mM) than in control (Figure 5). The strongest damaging effect to membrane lipids was observed at the KIO_{3} concentration of 10 mM (Figure 5).

When KIO_{3} was used together with Fe^{2+}+H_{2}O_{2}, the following results were obtained. Potassium iodate enhanced Fenton reaction-induced lipid peroxidation, when it was used in concentrations of 5 mM to 200 mM, with the strongest damaging effect of KIO_{3} found again for the concentration of 10 mM (Figure 6). Concentration-dependent effects of KIO_{3} used together with Fenton reaction substrates were similar to those caused by KIO_{3} alone (compare Figures 5 and 6).

In comparative experiment (i.e. in the presence and in the absence of Fenton reaction substrates), the addition of Fe^{2+}+H_{2}O_{2} enhanced KIO_{3}-induced lipid peroxidation, but only for KIO_{3} concentration ≤10 mM (Figure 7). Strong
prooxidative effects of KIO₃ in concentrations ≥25 mM was not enhanced by Fenton reaction substrates (Figure 7).

In turn, no significant differences were found for respective concentrations of KIO₃ in the presence or in the absence of Fe²⁺ (Figure 8).

Discussion

Molar concentrations of KI and KIO₃ were calculated in the present study with regard to whole compounds. Among chemical elements forming either KI or KIO₃, iodine is characterized by the highest molecular mass — much higher than potassium (K) and oxygen (O), thus it constitutes the crucial part of both compounds concerning their molecular masses, i.e. iodine constitutes 76.45% of molecular mass of KI, and in case of KIO₃ it constitutes 59.30% of the molecular mass of this compound. In turn, the molecular mass of KI constitutes 77.57% of that one of KIO₃, so the molecular masses of these two compounds are of the same order of magnitude. Therefore, concentrations of KI and of KIO₃, calculated in the present study, may be used in comparative analyses either of effects of iodide ions (I⁻) formed from both KI and KIO₃, or of effects of the whole compounds, i.e. KI and KIO₃.

It is worth mentioning that in vitro KI treatment of the thyroid cell line PCCl₃ resulted in the increased reactive oxygen species production [35]. Similar effect has not been evaluated after KIO₃ treatment.

Only few studies have been performed till now to compare effects of iodine present in two different sources, namely in KI and KIO₃. No differences were found between tissue (the thyroid gland, liver, kidney, muscle, abdominal fat tissue and skin) iodine content or blood thyroid hormone concentrations after in vivo treatment with high doses of either KI or KIO₃ [8]. In similar in vivo model the same group of authors evaluated some parameters of oxidative stress [36]. Different compounds of iodine, i.e. KI or KIO₃, have
similar effects on lipid peroxidation level (measured as MDA concentration) in the liver and the muscle, however certain differences were observed concerning mRNA expressions or the activities of antioxidative enzymes in different tissues [36]. However, such comparative studies have not been performed under in vitro conditions. The present study is the first one in which KI was found to be superior to KIO3 in the thyroid gland concerning oxidative damage to macromolecules.

More favourable effects of KI comparing to KIO3 were observed both, when each of compounds was used separately or together with Fenton reaction substrates. Concerning the first situation, both KI and KIO3 revealed – when used in high concentrations – damaging effects to membrane lipids in the thyroid. However, the difference between these unfavourable actions of KI and KIO3 was crucial. Namely, the damaging effect of KI decreased gradually with decreasing concentrations of this compound and these undesired effects were not observed for concentrations below 50 mM, thus concentrations corresponding to inorganic iodine level normally present in the thyroid under physiological conditions. On the basis of experimental findings [37-39] the concentration of inorganic iodine in the human or rat thyroid was calculated by the authors of the present work to be approx. 9 mM. Taking into account close similarity between human and porcine thyroid in terms of thyroid volume and of thyroid hormone synthesis with all elements and all steps of this process [40], it may be estimated that iodine concentration in porcine thyroid (used in the present study) is at similar level. Thus, the concentrations of KI resulting in thyroid level of inorganic iodine close to that observed under physiological conditions do not reveal prooxidative effects, at least in terms of oxidative damage to membrane lipids.

In opposite, when KIO3 was used alone, the highest lipid peroxidation was found for its concentration of 10 mM, thus corresponding to the physiological concentration in the thyroid, which was calculated to be 9 mM. It should be recalled that the same concentration of KI did not increase the level of lipid peroxidation (compare Figures 1 and 2).

When KI or KIO3 were added to the incubation medium together with Fenton reaction substrates, KI appeared to be also superior to KIO3 concerning their influence on lipid peroxidation in the thyroid gland. Whereas KI in concentrations of 5–100 mM (Figure 2), i.e. corresponding to physiological concentrations of inorganic iodine, diminished experimentally-induced lipid peroxidation, KIO3 did not reveal any protective action (Figure 5). Additionally, KI in concentration of 25 mM, thus being one order of magnitude higher than physiological iodine concentration, completely prevented Fenton reaction-induced lipid peroxidation. In turn, KIO3 enhanced Fenton reaction-induced lipid peroxidation, when it was used in concentrations of 5 mM to 200 mM, with the strongest damaging effect of KIO3 found again for the concentration of 10 mM (Figure 6).

Additionally it is clearly visible that prooxidative effects of KI was enhanced by Fenton reaction substrates. At the same time the damaging effects of KIO3 were so strong that they were only weakly enhanced by Fenton reaction substrates (compare Figures 1 and 2, Figures 5 and 6, Figures 3 and 7). These comparative analyses reveal additionally the superiority of KI over KIO3.

Ferroson ion (Fe2+), which was in our earlier study [31] documented to induce lipid peroxidation in the thyroid gland, when it was used as only one of Fenton reaction substrates, did not modify significantly in the present study the effect of either KI or of KIO3. This is probably due to the fact that prooxidative effects of Fe2+ alone is clearly weaker than those ones caused by both Fenton reaction substrates [31]. Potential mechanisms of differences between KI and KIO3 effects on lipid peroxidation in thyroid homogenates, observed in the present study, should be discussed. Thus, the following explanation is proposed.

The reduction of IO3- , the process occurring when the tissue is exposed to KIO3, requires the time and energy and possibly it is associated with unfavorable oxidative reactions and the damaging effects.

In turn, KIO3 belongs to halogenate salts, which are known for their potentially toxic effects [5,13,41]. In our earlier studies, one of halogenate salts, namely potassium bromate (KBrO3), being classified as carcinogen (group 2B according to IARC 1986 [42]), was shown to exert damaging effect to membrane lipids in porcine thyroid under
