THE COAREA FORMULA FOR SOBOLEV MAPPINGS

JAN MALÝ, DAVID SWANSON AND WILLIAM P. ZIEMER

Abstract. We extend Federer's coarea formula to mappings \( f \) belonging to the Sobolev class \( W^{1,p}(\mathbb{R}^n;\mathbb{R}^m) \), \( 1 \leq m < n \), \( p > m \), and more generally, to mappings with gradient in the Lorentz space \( L^{m,1}(\mathbb{R}^n) \). This is accomplished by showing that the graph of \( f \) in \( \mathbb{R}^{n+m} \) is a Hausdorff \( n \)-rectifiable set.

1. Introduction

The following equality, first proved by Federer in [F4] and termed the coarea formula, has proved to be a fundamental tool in analysis with a wide variety of applications:

\[
\int_{\Omega} g(x) |J_m f(x)| \, dx = \int_{\mathbb{R}^m} \int_{f^{-1}(y)} g(x) \, d\mathcal{H}^{n-m}(x) \, dy,
\]

where \( \Omega \subset \mathbb{R}^n \) is an open set, \( f : \Omega \to \mathbb{R}^m \) is Lipschitz, \( J_m f \) is its \( m \)-dimensional Jacobian, \( g : \Omega \to \mathbb{R} \) is integrable, and \( 1 \leq m < n \). Recall that \( |J_m f| \) is the square root of the sum of the squares of the determinants of the \( m \times m \) minors of the differential of \( f \). Using standard approximation methods (1.1) may be obtained from the special case where \( g \) is the indicator of a measurable set \( E \subset \mathbb{R}^n \):

\[
\int_{E} |J_m f(x)| \, dx = \int_{\mathbb{R}^m} \mathcal{H}^{n-m}(E \cap f^{-1}(y)) \, dy.
\]

Because of the usefulness of the coarea formula, a natural and compelling question is whether it will admit an extension to a larger class of mappings, in particular, to the class \( W^{1,1}_{\text{loc}}(\Omega; \mathbb{R}^m) \) of Sobolev mappings. When \( m = 1 \), it was shown by Federer [F3] that (1.2) is valid for mappings \( f \in W^{1,p}(\Omega) \), \( p \geq 1 \), provided that \( f \) is precisely represented, see (2.5) below. The case \( p > n \), including \( m = 2 \), has been considered by Van der Putten [VP].

One of the main objectives of this paper is to establish (1.2) for mappings \( f \) belonging to the Sobolev class \( W^{1,p}_{\text{loc}}(\Omega; \mathbb{R}^m) \). The following result is new for \( m > 1 \) and the proof simplifies the existing proof for \( m = 1 \).

1.1. Theorem. Suppose that \( 1 \leq m \leq n \) and that \( f \in W^{1,p}_{\text{loc}}(\Omega; \mathbb{R}^m) \) is precisely represented, where either \( p > m \) or \( p \geq m = 1 \). Then \( f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \)-rectifiable for almost all \( y \in \mathbb{R}^m \) and the coarea formula (1.2) holds for all measurable sets \( E \subset \Omega \).

Key words and phrases. Sobolev mapping, Orlicz space, coarea formula, area formula, rectifiability.

The research of the first author is supported in part by the Research Project MSM 113200007 from the Czech Ministry of Education, Grant No. 201/00/0767 from the Grant Agency of the Czech republic (GA ČR) and Grant No. 165/99 from the Grant Agency of Charles University (GA UK).
In the following theorem we denote by \( \bar{f} : \Omega \to \mathbb{R}^{n+m} \) the graph mapping \( \bar{f}(x) = (x, f(x)) \) and by \( \mathcal{G}_f \) the graph of \( f : \mathcal{G}_f = \bar{f}(\Omega) \subset \mathbb{R}^{n+m} \).

1.2. Theorem. Suppose that \( 1 \leq m \leq n \) and that \( f \in W^{1,p}_{\text{loc}}(\Omega; \mathbb{R}^m) \) is precisely represented, where either \( p > m \) or \( p \geq m = 1 \). Then \( \mathcal{G}_f \) is countably \( \mathcal{H}^n \) rectifiable and

\[
\mathcal{H}^n(\bar{f}(E)) = \int_E |J_n \bar{f}(x)| \, dx
\]

for all measurable sets \( E \subset \Omega \). In particular, \( \mathcal{H}^n(\bar{f}(E)) = 0 \) whenever \( \mathcal{L}^n(E) = 0 \).

The hypothesis \( p > m \) is necessary. In [3], [MM], an example of a continuous mapping \( f \in W^{1,m}(\mathbb{R}^m; \mathbb{R}^m) \) is exhibited which has an almost everywhere vanishing Jacobian and maps an interval \( I \) onto an \( m \)-cube. This may be easily modified in the case \( m \geq 2 \) to an example of a continuous mapping \( f \in W^{1,m}(\mathbb{R}^n; \mathbb{R}^m) \) which has an almost everywhere vanishing \( m \)-Jacobian and which maps each set of the form \( I \times \mathbb{R}^{n-m} \) onto an \( m \)-cube (cf. [3]), therefore violating the conclusions of Theorems 1.1 and 1.2. However, if we turn our attention to mappings whose gradients belong to the finer scale of Lorentz spaces, we obtain the following extension of the above stated theorems.

1.3. Theorem. Suppose that \( 1 \leq m \leq n \), that \( f \in W^{1,1}_{\text{loc}}(\Omega; \mathbb{R}^m) \) is precisely represented, and that \( |\nabla f| \in L^{m,1}(\Omega) \). Then \( f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \) rectifiable for almost all \( y \in \mathbb{R}^m \), the graph \( \mathcal{G}_f \) is countably \( \mathcal{H}^n \) rectifiable and the coarea formula (1.3) and area formula (1.2) hold for all measurable sets \( E \subset \Omega \).

The case \( m = n \) of Theorem 1.3 (and even the area counterpart \( m \geq n \)) follows from the work of Kauhanen, Koskela, and Malý [KKM] who generalized the area formula of Marcus and Mizeł [MM] to functions whose gradients lie in \( L^{1,1}(\Omega) \).

It is also possible to obtain results dealing with the borderline case \( p = m \) for mappings which are Hölder continuous. The following theorem provides a coarea counterpart to the results in [MM] on the area formula for Hölder continuous mappings in \( W^{1,n} \) (See also the recent developments in [M2], [MM], [M4]).

1.4. Theorem. Suppose that \( 1 \leq m \leq n \) and that \( f \in W^{1,m}(\Omega; \mathbb{R}^m) \) is a Hölder continuous mapping. Then \( f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \) rectifiable for almost all \( y \in \mathbb{R}^m \) and

\[
\int_E |J_m f(x)| \, dx = \int_{\mathbb{R}^m} \mathcal{H}^{n-m}(E \cap f^{-1}(y)) \, dy
\]

for all measurable sets \( E \subset \Omega \).

Theorem 1.4 is proven independently of any area estimates on the \( \mathcal{G}_f \) and in fact the proof can be modified to give an independent proof of Theorem 1.1 in the case \( p > m \), cf. Remark 1.2 below.

Weaker variants of the coarea and area formulas use the integralgeometric measure \( \mathcal{I}^q \) instead of Hausdorff measure \( \mathcal{H}^q \). Hajłasz [4] proved such a version of the coarea formula for \( W^{1,p} \)-mappings \( (p > m) \). We present a version of Theorem 1.2 in the borderline case \( p = m \) under the assumption of Hölder continuity. We have not been able to obtain such a result with the Hausdorff measure.
1.5. Theorem. Suppose that $1 \leq m \leq n$ and that $f \in W^{1,m}(\Omega; \mathbb{R}^m)$ is a Hölder continuous mapping. Then $\mathcal{G}_f$ is countably $\mathcal{I}$ rectifiable and
\[
\mathcal{I}^n(\bar{f}(E)) = \int_E |J_n \bar{f}(x)| \, dx
\]
for all measurable sets $E \subset \Omega$.

The results listed above are easily localized from $\mathbb{R}^n$ to $\Omega$. For the proofs we may assume that $\Omega = \mathbb{R}^n$ and that the global norms of the considered mappings are finite. Since our results follow from the area formulas in [MM] and [KKM] when $m = n$ we also assume throughout that $m < n$.

2. Preliminaries

We denote by $\mathcal{L}^n(E)$ the Lebesgue measure of a set $E \subset \mathbb{R}^n$ and by $\mathcal{H}^q(E)$ the $q$-dimensional Hausdorff measure of $E$. If $q$ is an integer then $\mathcal{H}^q$ is countably $\mathcal{H}$ rectifiable if there exist subsets $E_k \subset \mathbb{R}^q$ and Lipschitz mappings $g_k : E_k \to \mathbb{R}^n$ with the property that
\[
\mathcal{H}^q \left( E \setminus \bigcup_{k=1}^\infty g_k(E_k) \right) = 0.
\]

The $q$-dimensional Hausdorff content $\mathcal{H}^q_\infty(E)$ of $E$ is the infimum of the sums
\[
\sum_{j=1}^\infty \alpha_q \left( \frac{\text{diam} E_j}{2} \right)^q
\]
corresponding to all countable coverings of $E$ by sets $\{E_j\}_{j=1}^\infty$. Here
\[
\alpha_q = \frac{\pi^{q/2}}{\Gamma(\frac{q}{2} + 1)},
\]
which is the volume of the unit ball in $\mathbb{R}^q$ if $q$ is integer. Observe that $\mathcal{H}^q(E) = 0$ if and only if $\mathcal{H}^q_\infty(E) = 0$. The integral average of a function $g$ over the set $E$ is defined as
\[
\int_E g(y) \, dy = \frac{1}{\mathcal{L}^n(E)} \int_E g(y) \, dy.
\]

Given $1 \leq p \leq \infty$ the Sobolev space $W^{1,p}(\Omega)$ consists of those functions $f \in L^p(\Omega)$ with the property that the distributional gradient $Df$ of $f$ may be identified with a function $\nabla f \in L^p(\Omega; \mathbb{R}^n)$. $W^{1,p}(\Omega)$ is a Banach space with respect to the norm
\[
\|f\|_{1,p,\Omega} := \|f\|_{L^p(\Omega)} + \|\nabla f\|_{L^p(\Omega)}.
\]
The class $W^{1,p}(\Omega; \mathbb{R}^m)$, $m \geq 1$, consists of those mappings $f : \Omega \to \mathbb{R}^m$ whose component functions each belong to $W^{1,p}(\Omega)$. Qualitative properties like Lebesgue points, approximate differentiability, etc. may be investigated componentwise.

We will also consider a refined scale of Sobolev spaces consisting of those functions with gradients in Lorentz and Orlicz spaces. If $g$ is a measurable function on $\Omega$, we define the distribution function of $g$ as
\[
\mu_g(s) = \mathcal{L}^n \left( \{ x \in \Omega : |g(x)| > s \} \right).
\]
We set
\[ \|g\|_{L^{m,1}(\Omega)} = \int_0^\infty \mu_g(s)^{1/m} ds. \]
We say that \( g \) belongs to the Lorentz space \( L^{m,1}(\Omega) \) if \( \|g\|_{L^{m,1}(\Omega)} < \infty \).

It is known that this space can be expressed as a union of Orlicz spaces. A function \( F : [0, +\infty) \to \mathbb{R} \) is said to be a Young function if \( F \) is convex, nonnegative and satisfies
\[ F(t) = 0 \iff t = 0. \]
The Orlicz space \( L^F(\Omega) \) is then defined as the space of all measurable functions \( g \) on \( \Omega \) for which there exists \( \lambda > 0 \) such that
\[ \int_{\Omega} F(|g|/\lambda) \, dx \leq 1. \]

The following result is proven in [MSZ].

\[ \textbf{2.1. Proposition.} \] Let \( g \in L^{m,1}(\Omega) \) and \( 1 < q < m < p \). Then there is a \( C^1 \) Young function \( F \) and a constant \( C = C(m,p,q) > 0 \) such that
\[
\begin{align*}
(2.1) & \quad \int_{\Omega} F(|g|) \, dx \leq C \|g\|_{L^{m,1}(\Omega)}^m \\
(2.2) & \quad \int_0^\infty F'(t)^{-\frac{m}{m-1}} \, dt \leq C \\
(2.3) & \quad q \leq \frac{tF'(t)}{F(t)} \leq p, \quad t > 0.
\end{align*}
\]

If a Young function \( F \) satisfies (2.3), then the function \( t^p F(t) \) is nondecreasing and the function \( t^q F(t) \) is nonincreasing. In this case the Orlicz space \( L^F(\Omega) \) coincides with the set of all measurable functions for which the integral \( \int_{\Omega} F(|g|) \, dx \) converges.

In the following paragraphs we recall the definition of capacity and certain pointwise properties of Sobolev functions. We refer the reader to [FZ] for the proofs.

For \( 1 \leq p < \infty \) the \( p \)-capacity \( \gamma_p(E) \) of a set \( E \subset \mathbb{R}^n \) is the infimum of numbers of the form
\[ \int_{\mathbb{R}^n} (|u|^p + |\nabla u|^p) \, dx \]
corresponding to all \( u \in W^{1,p}(\mathbb{R}^n) \) with the property that \( u \geq 1 \) on a neighborhood of \( E \). \( p \)-capacity is related to Hausdorff measure as follows: if \( p > 1 \) and \( \gamma_p(E) = 0 \), then \( H^q(E) = 0 \) for all \( q > n - p \), whereas \( H^{n-p}(E) < \infty \) implies \( \gamma_p(E) = 0 \). As for the case \( p = 1 \), Fleming [Fl] proved that \( \gamma_1(E) = 0 \) if and only if \( H^{n-1}(E) = 0 \). Related statements concerning the Hausdorff content are given in Lemma 5.1 and Theorem 5.5 below.

A function \( f : \Omega \to \mathbb{R}^n \) is said to be \( p \)-quasicontinuous if for every \( \varepsilon > 0 \) there exists an open set \( G \) with \( \gamma_p(G) < \varepsilon \) so that \( f|_{\Omega \setminus G} \) is continuous. Any two \( p \)-quasicontinuous functions which agree almost everywhere agree up to a set \( E \) with \( \gamma_p(E) = 0 \).
If \( \Omega \subset \mathbb{R}^n \) is an open set and \( f \in L^1_{\text{loc}}(\Omega) \), then a function \( \tilde{f} \) is said to be a precise representative of \( f \) if

\[
\tilde{f}(x) := \lim_{r\to 0} \int_{B(x,r)} f(y) \, dy
\]

at all points \( x \) where this limit exists. It is clear from the Lebesgue differentiation theorem that any function \( f \in L^1_{\text{loc}}(\Omega) \) may be modified on a set of Lebesgue measure zero so as to be precisely represented and that any two precise representatives coincide almost everywhere. A mapping \( f \in L^1_{\text{loc}}(\Omega; \mathbb{R}^m) \) is said to be precisely represented if each of its component functions is a precise representative.

Fundamental properties of functions \( f \in W^{1,p}(\Omega) \) are that the limit (2.3) exists for all \( x \) outside a set \( E \) with \( \gamma_p(E) = 0 \), and that any precise representative of a function \( f \in W^{1,p}(\Omega) \) is \( p \)-quasicontinuous. Thus if \( p > m \) or \( p = m = 1 \), any two precise representatives agree outside a set \( E \) with \( \mathcal{H}^{n-m}(E) = 0 \). Since sets of \( \mathcal{H}^{n-m} \) measure zero are negligible for results of Theorem 1.1 and Theorem 1.2, it follows that their statements will hold for any \( p \)-quasicontinuous representative and even any representative with Lebesgue points \( \mathcal{H}^{n-m} \) almost everywhere.

Similarly it is proven in [MSZ] that if \( f \in W^{1,1}_{\text{loc}}(\Omega) \) and \( |\nabla f| \in L^{m,1}(\Omega) \), then any precise representative of \( f \) is defined up to a set \( E \) with \( \mathcal{H}^{n-m}(E) = 0 \). It follows that the statement of Theorem 3.3 will hold for any representative with Lebesgue points \( \mathcal{H}^{n-m} \) almost everywhere.

### 3. Lusin’s Condition (N)

A mapping \( f : \mathbb{R}^n \to \mathbb{R}^k \), \( k \geq n \), is said to satisfy Lusin’s condition (N) if \( \mathcal{H}^n(f(E)) = 0 \) whenever \( E \subset \mathbb{R}^n \) satisfies \( \mathcal{L}^n(E) = 0 \). In this section we show that if \( f \in W^{1,p}(\mathbb{R}^n; \mathbb{R}^m) \) and \( \tilde{f} : \mathbb{R}^n \to \mathbb{R}^{n+m} \) satisfies condition (N) then the conclusions of Theorems 1.1 and 1.2 hold. This holds without any particular restriction on \( p \). First we require two well known lemmas.

**3.1. Lemma** (Eilenberg inequality, [E]). Suppose \( m \leq d \leq m + n \), \( A \subset \mathbb{R}^{n+m} \), and \( h : A \to \mathbb{R}^m \) is Lipschitz. Then

\[
\int_A \mathcal{H}^{d-m}(A \cap h^{-1}(y)) \, d\mathcal{H}^m(y) \leq C(\text{Lip } h)^m \mathcal{H}^d(A),
\]

where \( \int^* \) denotes the upper integral, \( \text{Lip } f \) is the Lipschitz constant of \( f \), and \( C = C(m) \) is a constant depending only on \( m \).

**3.2. Lemma.** If \( f \in W^{1,1}_{\text{loc}}(\mathbb{R}^n; \mathbb{R}^m) \) then there exist Lipschitz functions \( f_k : \mathbb{R}^n \to \mathbb{R}^m \) and disjoint subsets \( E_k \) of \( \mathbb{R}^n \) such that \( f = f_k \) on \( E_k \) and \( \mathcal{L}^n(\mathbb{R}^n \setminus \cup E_k) = 0 \).

This follows from the a.e. approximate differentiability of \( f \) [FS 3.1.4], [BZ] and a general property of a.e. approximately differentiable functions [FS 3.1.8].

**3.3. Theorem.** Let \( f \in W^{1,1}_{\text{loc}}(\mathbb{R}^n; \mathbb{R}^m) \), \( 1 \leq m \leq n \), and suppose that \( f \) satisfies condition (N). Then \( f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \) rectifiable for almost all \( y \in \mathbb{R}^m \), the graph \( \mathcal{G}_f \) is countably \( \mathcal{H}^n \) rectifiable and the coarea formula (1.2) and area formula (3.3) hold for all measurable sets \( E \subset \Omega \).

**Proof.** Choose functions \( f_k \) and sets \( E_k \) as in Lemma 3.2. Since \( f_k = f \) on \( E_k \) and \( \nabla f_k = \nabla f \) a.e. on \( E_k \), it follows from the classical area formula for Lipschitz
functions [F5, 3.2.5] that that

\[ (3.1) \quad \mathcal{H}^n(f(E)) = \int_{E} |J_n f(x)| \, dx \]

whenever \( E \subset E_k \). Moreover (3.1) will be satisfied whenever \( L^n(E) = 0 \) provided that \( f \) satisfies condition (N). Therefore the monotone convergence theorem implies (3.1) for all \( E \subset \mathbb{R}^n \), as desired. That the graph \( \mathcal{G}_f \) is countably \( \mathcal{H}^n \) rectifiable is evident since

\[ \mathcal{H}^n \left( \mathcal{G}_f \setminus \bigcup_{k=1}^{\infty} \bar{f}(E_k) \right) = 0. \]

Now denote by \( \pi : \mathbb{R}^{n+m} \to \mathbb{R}^n \) and \( \rho : \mathbb{R}^{n+m} \to \mathbb{R}^m \) the projections

\[ \pi(x, x_{n+1}, \ldots, x_{n+m}) = x \quad \text{and} \quad \rho(x, x_{n+1}, \ldots, x_{n+m}) = (x_{n+1}, \ldots, x_{n+m}). \]

Let \( E \subset \mathbb{R}^n \) satisfy \( L^n(E) = 0 \) and apply the Eilenberg inequality with \( A = \bar{f}(E) \), \( h = \rho \), and \( d = n \). Then

\[ \int_{\mathbb{R}^m} \mathcal{H}^{n-m}(A \cap \rho^{-1}(y)) \, d\mathcal{H}^m(y) \leq C \mathcal{H}^n(\bar{f}(E)) = 0. \]

Now, \( A \cap \rho^{-1}(y) = \{(x, f(x)) \in \mathbb{R}^{n+m} : x \in E, f(x) = y\} \), so it follows that \( \pi(A \cap \rho^{-1}(y)) = E \cap f^{-1}(y) \). Since Hausdorff measures do not increase on projection we conclude

\[ (3.2) \quad \int_{\mathbb{R}^m} \mathcal{H}^{n-m}(E \cap f^{-1}(y)) \, d\mathcal{H}^m(y) = 0. \]

From (3.2) above we have that

\[ (3.3) \quad \int_{\mathbb{R}^m} \mathcal{H}^{n-m}(E \cap f^{-1}(y)) \, d\mathcal{H}^m(y) = \int_{E} |J_m f(x)| \, dx \]

holds whenever \( E \subset E_k \), so again the monotone convergence theorem implies that (3.1) holds for all \( E \subset \mathbb{R}^n \). That \( f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \) rectifiable for almost \( y \in \mathbb{R}^m \) follows from the fact that for each \( k \), \( E_k \cap f^{-1}(y) = E_k \cap f^{-1}(y) \) is countably \( \mathcal{H}^{n-m} \) rectifiable for almost \( y \in \mathbb{R}^m \) (see [F5, 3.2.15]), and that \( \mathcal{H}^{n-m}(E \cap f^{-1}(y)) = 0 \) for almost all \( y \) whenever \( L^n(E) = 0 \). \( \square \)

4. A general criterion for condition N

Throughout this section we denote by \( \pi : \mathbb{R}^{n+m} \to \mathbb{R}^n \) the projection

\[ \pi(x, x_{n+1}, \ldots, x_{n+m}) = x. \]

4.1. Lemma. Suppose \( m \leq d \leq m + n \). Let \( E \subset \mathbb{R}^{n+m} \). Then

\[ \mathcal{H}^d_{\infty}(E) \leq C(\text{diam } E)^m \mathcal{H}^{d-m}_{\infty}(\pi(E)). \]

where \( C = C(m, n, d) \).

Proof. Assume \( \text{diam } E < \infty \). Cover \( \pi(E) \) with a sequence of sets \( \{A_k\}_{k=1}^{\infty} \) of finite and positive diameter. For each \( k \) let \( N_k \) denote the greatest integer satisfying

\[ (N_k - 1) \cdot (\text{diam } A_k) < \text{diam } E. \]
The set $E \cap \pi^{-1}(A_k)$ is easily seen to be contained in a cylinder of the form $A_k \times Q_k$, where $Q_k$ is a cube in $\mathbb{R}^m$ with sidelength $\text{diam } E$. Since $N_k \cdot (\text{diam } A_k) \geq \text{diam } E$, $Q_k$ may be covered by $N_k^m$ cubes $\{Q_k^j\}$ of sidelength $\text{diam } A_k$. It follows that

$$\mathcal{H}_\infty^d(E \cap \pi^{-1}(A_k)) \leq C \sum_{j=1}^{N_k^m} \left( \frac{(\text{diam } (A_k \times Q_k^j)) \cdot \text{diam } A_k}{2} \right)^d \leq CN_k^m \cdot (\text{diam } A_k)^d \leq C(\text{diam } A_k + \text{diam } E)^m \cdot (\text{diam } A_k)^{d-m}.$$ 

Since $\text{diam } A_k \leq \text{diam } \pi(E) \leq \text{diam } E$, summing over $k$ shows that

$$\mathcal{H}_\infty^d(E) \leq C(\text{diam } E)^m \sum_{k=1}^{\infty} (\text{diam } A_k)^{d-m}.$$ 

The result follows by taking the infimum over all coverings $\{A_k\}$.  

\[ 4.2. \text{ Corollary.} \quad \text{Suppose } m \leq d \leq m + n. \quad \text{Let } E \subset \mathbb{R}^{n+m}, \; \mathcal{H}^{d-m}(\pi(E)) = 0. \quad \text{Then } \mathcal{H}^d(E) = 0. \]

The following lemma concerns a measurability property of the graph of a mapping $f$ and is used in the proof of Theorem 4.4 below. Recall that $\bar{f}$ denotes the graph mapping $\bar{f}(x) = (x, f(x))$ and $G_f$ the graph set $\bar{f}(\mathbb{R}^n) \subset \mathbb{R}^{n+m}$.

\[ 4.3. \text{ Lemma.} \quad \text{Let } f : \mathbb{R}^n \to \mathbb{R}^m \text{ be an } \mathcal{L}^n \text{ measurable mapping. Then } \pi(G_f \cap E) \text{ is } \mathcal{L}^n \text{ measurable for every Borel set } E \subset \mathbb{R}^{n+m}. \]

\[ \text{Proof.} \quad \text{Let } f^* \text{ be a Borel measurable representative of } f. \quad \text{The graph } G_{f^*} \text{ of such a mapping is a Borel subset of } \mathbb{R}^{n+m}, \text{ implying that the projection } \pi(G_{f^*} \cap E) \text{ is a Borel subset of } \mathbb{R}^n \text{ for any Borel set } E \subset \mathbb{R}^{n+m}. \text{ See [3, §31, VII]. Since } f \text{ and } f^* \text{ agree up to a set of } \mathcal{L}^n \text{ measure zero, so do the sets } \pi(G_f \cap E) \text{ and } \pi(G_{f^*} \cap E). \quad \text{Thus } \pi(G_f \cap E) \text{ is } \mathcal{L}^n \text{ measurable.} \]

The following result yields a criterion similar to that of Radó and Reichelderfer, see [2, M3].

\[ 4.4. \text{ Theorem.} \quad \text{Suppose that } 1 \leq m \leq n. \quad \text{Let } f \in W_{1,1}^{1,1}(\mathbb{R}^n; \mathbb{R}^m) \text{ and suppose that there is } \theta \in L^1_{\text{loc}}(\mathbb{R}^n) \text{ such that} \]

$$\mathcal{H}_{m}^{n-m}(\pi(G_f \cap B(z, r))) \leq r^{-m} \int_{\pi(G_f \cap B(z, 4r))} \theta(x) \, dx \quad \text{for all } z \in \mathbb{R}^{n+m} \text{ and } r > 0.$$ 

Then there is a constant $C = C(m, n)$ depending only on $m$ and $n$ so that

$$\mathcal{H}^n(\bar{f}(E)) \leq C \int_E \theta(x) \, dx.$$ 

for all $\mathcal{L}^n \text{ measurable } E \subset \mathbb{R}^n$. In particular, $\bar{f}$ satisfies condition (N).

\[ \text{Proof.} \quad \text{Define a set function } \sigma \text{ on } \mathbb{R}^{n+m} \text{ by} \]

$$\sigma(E) = \int_{\pi(G_f \cap E)} \theta(x) \, dx.$$
Lemma 4.1 with $d = n$ and (4.1) imply that
\[ H_n^\infty (G_f \cap B(z, r)) \leq C r^m H_{n-m}^\infty (\pi(G_f \cap B(z, r))) \]
\[ \leq C \int_{\pi(G_f \cap B(z, 4r))} \theta(x) \, dx \]
\[ = C \sigma(B(z, 4r)) \]
for any $z \in \mathbb{R}^{n+m}$ and $r > 0$. Using the fact that
\[ \limsup_{r \to 0^+} r^{-n} H_n^\infty (G_f \cap B(z, r)) \geq C \]
for $H^n$ almost every $z \in G_f$ (\[F2, \text{Lemma 10.1}\]), it follows that
\[ \limsup_{r \to 0^+} r^{-n} \sigma(B(z, r)) \geq C \]
(4.2) for $H^n$ almost all $z \in G_f$. Now, Lemma 4.3 implies that $\sigma$ is a measure on the Borel $\Sigma$-algebra of $\mathbb{R}^{n+m}$, and so it may be extended to a regular Borel (outer) measure $\sigma^*$ on all of $\mathbb{R}^{n+m}$ in the usual way:
\[ \sigma^*(E) := \inf \{ \sigma(B) : E \subset B, B \text{ a Borel set} \} \]
Since $\theta$ is locally integrable it follows that $\sigma^*$ is a Radon measure on $\mathbb{R}^{n+m}$. Therefore $\[F2, \text{Theorem 10.3}\]$, \[M, \text{Theorem 6.9}\], and (4.2) imply that
\[ H^n(E) \leq C \sigma^*(E) \leq C \sigma(G \times \mathbb{R}^m) = C \int_G \theta(x) \, dx. \]
The proof is completed by taking the infimum over all such $G$. \qed

5. CAPACITARY ESTIMATES

The next lemma gives a capacitary estimate for $W^{1,1}$ which relates the 1-capacity with the $(n-1)$-dimensional Hausdorff content. This result is due to Fleming $\[F\]$, whose proof depends on information based on BV functions, in particular sets of finite perimeter. We give an independent proof which circumvents the need for BV theory.

5.1. Lemma. Let $E \subset \mathbb{R}^n$. Then $H_{n-1}^\infty(E) \leq C \gamma_1(E)$, where $C = C(n)$.

Proof. Let $u$ be a test function for the capacity. Let us consider the continuous monotone real function
\[ \psi(t) = \int_{\{0 < u < t\}} (|u| + |\nabla u|) \, dy. \]
Then $\psi$ is a.e. differentiable and
\[ \int_0^1 \psi'(t) \, dt \leq \psi(1) - \psi(0) = \psi(1). \]
Hence there exists $s \in (0, \ell)$ such that $\psi'(s) < 2\psi(1)$. We find $\delta > 0$ such that
\[ \frac{\psi(s') - \psi(s)}{s' - s} \leq 2\psi(1) \quad \text{for each } s' \in (s, s + \delta). \]
(5.1)
Let $x \in E$. Then $u(x) \geq 1$ in a neighborhood of $x$ and so the set
\[ R_x := \{ \rho : |B(x, \rho) \cap \{u \geq s\}| < \frac{1}{2} |B(x, \rho)| \} \]
is nonempty. Let us define
\[ r_x = \sup_{x \in E} R_x. \]
Then obviously \( \sup_{x \in E} r_x < \infty \) and
\[
|B(x, r_x) \cap \{ u < s \}| \leq \frac{1}{2} |B(x, r_x)|.
\]
and
\[
|B(x, r_x) \cap \{ u \geq s \}| \leq \frac{1}{2} |B(x, r_x)|.
\]
We use the Besicovitch covering theorem to extract a (finite or infinite) sequence \( \{ B_j \}_{j \in I} \) of balls \( B_j = B(x_j, r_j) \) from \( \{ B(x, r_x) : x \in E \} \) such that it covers the set \( E \) and its overlap multiplicity is bounded by an integer \( M \) depending only on \( n \). Here \( I = \mathbb{N} \) or \( I = \{ 1, 2, \ldots, i_{\max} \} \). Fix \( i \in I \). Using (5.3), we find a level \( t_i \in (s, s + \delta) \) such that
\[
|B(x_j, r_j) \cap \{ u \leq t_i \}| \leq \frac{3}{4} |B(x_j, r_j)|, \quad j = 1, \ldots, i.
\]
Consider the truncated function
\[
u_i = \begin{cases} t_i & \text{on } \{ u \geq t_i \}, \\ s & \text{on } \{ u \leq s \}, \\ u & \text{on } \{ s < u < t_i \}. \end{cases}
\]
Let \( s_{i,j} \) be a median value of \( \nu_i \) on \( B_j \). From (5.2) and (5.4) we infer that
\[
t_i - s \leq C \int_{B_j} |\nabla \nu_i| \, dy.
\]
This means
\[
r_j^{n-1} \leq \frac{C}{t_i - s} \int_{B_j} (|\nabla \nu_i| + |\nu_i|) \, dy.
\]
Summing over \( j = 1, \ldots, i \) and using (5.3) we obtain
\[
\sum_{j=1}^{i} r_j^{n-1} \leq \frac{C}{t_i - s} \int_{B} (|\nabla \nu_i| + |\nu_i|) \, dy \leq \frac{CM}{t_i - s} \int_{B} (|\nabla \nu_i| + |\nu_i|) \, dy
\]
\[
= \frac{CM}{t_i - s} \int_{B \cap \{ s \leq u < t_i \}} (|u| + |\nabla u|) \, dy = CM \frac{\psi(t_i) - \psi(s)}{t_i - s}
\]
\[
\leq C \psi(1) M.
\]
We can pass with \( i \) to \( i_{\max} \) or \( \infty \) and we obtain
\[
H_{\infty}^{n-1}(E) \leq C \psi(1) \leq \int_{\mathbb{R}^n} (|u| + |\nabla u|) \, dy
\]
as required.

**5.2. Corollary.** Let \( E \subset \mathbb{R}^n \). Suppose that \( u \in W^{1,1}(\mathbb{R}^n) \) is precisely represented and that \( u \geq 1 \) on \( E \). Then
\[
H_{\infty}^{n-1}(E) \leq C \int_{\mathbb{R}^n} (|\nabla u| + |u|) \, dx.
\]
Proof. Any precise representative of \( u \in W^{1,1}(\mathbb{R}^n) \) has Lebesgue points \( \mathcal{H}^{n-1} \)-a.e., cf. [F], [FZ]. Hence we may assume that \( u \) has a Lebesgue point at \( \mathcal{H}^{n-1} \)-a.e. point of \( x \in E \). Given \( \varepsilon > 0 \), let \( \{u_k\} \) be a sequence of smooth function approximating \( u \) and obtained by mollification, such that
\[
\|u_k - u\|_{1,1} \leq 2^{-k-1}\varepsilon.
\]
Set
\[
w = u_1 + \sum_{k=1}^{\infty} |u_{k+1} - u_k|.
\]
Then \( w \in W^{1,1}(\mathbb{R}^n), \|w\|_{1,1} \leq \|u\|_{1,1} + \varepsilon \) and \( w \geq 1 \) on a neighborhood of \( E \). Hence
\[
\mathcal{H}_\infty^{n-1}(E) \leq C \int_{\mathbb{R}^n} (|\nabla w| + |w|) \, dx \leq C \int_{\mathbb{R}^n} (|\nabla u| + |u|) \, dx + C\varepsilon.
\]
Letting \( \varepsilon \to 0 \) we obtain the assertion. \( \square \)

For the proofs of Theorems 1.1 and 1.2 we need the well known relation between the \( p \)-capacity and the Hausdorff content, see e.g. [AH, Theorem 5.1.13]. This result goes back to Frostman (\( p = 2 \)) and the case of general \( p \) is due to Reshetnyak [R] and Maz’ya and Havin [MH].

5.3. Theorem. Suppose that \( 1 \leq m < p \) and \( E \subset \mathbb{R}^n \). Then
\[
\mathcal{H}_\infty^{n-m}(E) \leq C \gamma_p(E),
\]
where \( C = C(n, m, p) \).

Since precise representatives of functions \( u \in W^{1,p}(\mathbb{R}^n) \) have Lebesgue points \( \mathcal{H}^{n-m} \) almost everywhere [FZ] we may continue as in the proof of Corollary 5.3 to obtain the following.

5.4. Corollary. Suppose that \( 1 \leq m < p \), \( E \subset \mathbb{R}^n \), \( u \in W^{1,p}(\mathbb{R}^n) \) is precisely represented, and that \( u \geq 1 \) on \( E \). Then
\[
\mathcal{H}_\infty^{n-m}(E) \leq C \int_{\mathbb{R}^n} (|\nabla u|^p + |u|^p) \, dx.
\]

Finally, to reach the generality of Theorem 1.3 we need the following capacitary estimate derived in [MSZ].

5.5. Theorem. Suppose that \( m > 1 \) is an integer. Let \( F \) be a Young function satisfying (2.2) and (2.3). Let \( E \subset \mathbb{R}^n \). Suppose that \( u \in W^{1,1}_{loc}(\mathbb{R}^n) \) is precisely represented, \( u \geq 1 \) on \( E \). Then
\[
\mathcal{H}_\infty^{n-m}(E) \leq C \int_{\mathbb{R}^n} (F(|\nabla u|) + F(|u|)) \, dx.
\]

6. Application of the General Criterion

In this section we prove Theorem 1.3. The reader interested only in the Lebesgue scale of spaces may read the arguments with \( F(t) = t^p \) and appeal to Corollary 5.4. This is sufficient to establish Theorems 1.1 and 1.2. To prove the more general result we use the estimate in Theorem 5.5.
Proof. In view of Theorem 3.3 it is sufficient to verify the assumptions of Theorem 4.4. Select a point \( z \in \mathbb{R}^{n+m} \) and \( r > 0 \). Writing \( z = (x_0, y_0) \) we have
\[
\mathcal{G}_f \cap B(z, r) \subset \mathcal{G}_f \cap [B(x_0, r) \times B(y_0, r)]
\]
hence
\[
\pi (\mathcal{G}_f \cap B(z, r)) \subset B(x_0, r) \cap f^{-1}(B(y_0, r)).
\]
Let \( E = B(x_0, r) \cap f^{-1}(B(y_0, r)) \) and define \( \hat{E} \) by
\[
\hat{E} = \frac{1}{2r}(E - x_0) = \{ x \in \mathbb{R}^n : x_0 + 2rx \in E \}.
\]
Then
\[
\mathcal{H}^{n-m}_{\infty}(\hat{E}) = (2r)^{m-n}\mathcal{H}^{n-m}_{\infty}(E).
\]
and thus
\[
(6.1) \quad \mathcal{H}^{n-m}_{\infty}(\pi(\mathcal{G}_f \cap B(z, r))) \leq Cr^{n-m}\mathcal{H}^{n-m}_{\infty}(\hat{E}),
\]
where \( C = C(m, n) \). Now, \( \xi \in \hat{E} \) implies that
\[
|\xi| \leq \frac{1}{2} \quad \text{and} \quad \frac{|f(x_0 + 2r\xi) - f(x_0)|}{2r} \leq \frac{1}{2}.
\]
Thus we consider the test function \( u\eta \) where
\[
u(\xi) = 2\left(1 - \frac{|f(x_0 + 2r\xi) - f(x_0)|}{2r}\right) +
\]
and \( \eta \) is a smooth cutoff function such that \( \chi_{B(0, \frac{1}{2})} \leq \eta \leq \chi_{B(0, 1)} \). If \( m = 1 \), we set \( F(t) = t \) and apply Corollary 5.2 to the function \( u\eta \). If \( m > 1 \), we use Proposition 2.1 to find a Young function \( F \) satisfying (2.2) and (2.3) such that
\[
\int_\Omega F(|\nabla u|) \, dx < \infty
\]
and apply Theorem 5.3 to the function \( u\eta \). In either case we obtain
\[
\mathcal{H}^{n-m}_{\infty}(\hat{E}) \leq C \int_{B(0,1)} (|u\eta|) + F(|\nabla (u\eta)|) \, d\xi
\]
\[
\leq C \int_{B(0,1) \cap \{u > 0\}} (1 + F(|\nabla u|)) \, d\xi
\]
Applying the change of variable \( x \rightarrow x_0 + 2r\xi \) this becomes
\[
(6.2) \quad \mathcal{H}^{n-m}_{\infty}(\hat{E}) \leq Cr^{-n} \int_{B(x_0, 2r) \cap f^{-1}(B(y_0, 2r))} (1 + F(|\nabla u|)) \, dx.
\]
Since
\[
B(x_0, 2r) \cap f^{-1}(B(y_0, 2r)) \subset \pi(\mathcal{G}_f \cap B(z, 4r))
\]
(6.1) and (6.2) above imply
\[
\mathcal{H}^{n-m}_{\infty}(\pi(\mathcal{G}_f \cap B(z, r))) \leq Cr^{-m} \int_{\pi(\mathcal{G}_f \cap B(z, 4r))} (1 + F(|\nabla u|)) \, dx,
\]
verifying the assumptions of Theorem 4.4 with \( \theta = C(1 + F(|\nabla u|)) \) and thus concluding the proof. \( \square \)
We now establish a result that yields Theorem 1.1 under a condition that allows some of the coordinate functions to be members of \(W^{1,p}(\mathbb{R}^n)\), \(p < m\), provided that the remaining ones are Lipschitz. For this purpose, let \(1 \leq k < m < n\) and let \(h: \mathbb{R}^n \to \mathbb{R}^m\) have the form
\[
h = (f_1, \ldots, f_k, g_{k+1}, \ldots, g_m)
\]
with \(f_1, \ldots, f_k \in W^{1,p}(\mathbb{R}^n), p > k\), and \(g_{k+1}, \ldots, g_m\) Lipschitz.

6.1. Theorem. With \(h\) as above, \(|Jh| \in L^1(\mathbb{R}^n)\) and
\[
\int_{\mathbb{R}^n} |Jh| \, dx = \int_{\mathbb{R}^n} H^{n-m}(h^{-1}(y)) \, dy
\]
for each measurable set \(E \subset \mathbb{R}^n\).

Proof. By Theorem 3.3 it suffices to show that \(H^n(f(N)) = 0\) whenever \(N \subset \mathbb{R}^n\) and \(\mathcal{L}^n(N) = 0\). Write \(h = (f, g)\) with \(f = (f_1, \ldots, f_k)\) and \(g = (g_{k+1}, \ldots, g_m)\) and let \(N \subset \mathbb{R}^n\) satisfy \(\mathcal{L}^n(N) = 0\). Identify \(\mathbb{R}^{n+k}\) with \(\mathbb{R}^n \times \mathbb{R}^k\) and write \(z \in \mathbb{R}^{n+k}\) as \(z = (z', z'')\) with \(z' \in \mathbb{R}^n\), \(z'' \in \mathbb{R}^k\). By Theorem 1.2 the set \(f(N) \subset \mathbb{R}^{n+k}\) has \(H^n\) measure zero. Define \(g^*: \mathbb{R}^{n+k} \to \mathbb{R}^{n+m}\) by \(g^*(z) = (z, g(z''))\). Then \(g^*\) is Lipschitz, \(h = g^* \circ f\), and therefore \(h(N) = g^* \circ f(N)\) has \(H^n\) measure zero in \(\mathbb{R}^{n+m}\).

7. Hölder continuous mappings

In this section we prove Theorem 1.4. The following result from [HM] plays a crucial role in the proof.

7.1. Theorem. Let \(p < n\), \(a > 0\), \(\beta \in (0,1)\) and \(\gamma > 0\). Let \(\Omega \subset \mathbb{R}^n\) be an open set and \(u \in W^{1,n}(\Omega)\) be a nonnegative function such that \(u > 0\) a.e. Let
\[
Z = \left\{ z \in \Omega : \limsup_{r \to 0} r^{-\beta} \int_{B(z,r)} u \, dx < \gamma \right\}.
\]
Suppose that \(H^{n-m}(Z) > a\). Then there exists a compact set \(F \subset \Omega \setminus Z\) such that \(\mathcal{L}^n(F) > 0\) and
\[
\sup_{F} u_m \leq C \int_{F} |\nabla u|^m \, dx,
\]
where \(C = C(n, m, a, \beta)\).

Proof of Theorem 1.4. As in the proof of Theorem 1.1 above it is sufficient to verify (7.2) whenever \(E \subset \mathbb{R}^n\) and \(\mathcal{L}^n(E) = 0\). Find an open set \(\Omega\) such that \(E \subset \Omega\) and
\[
\int_{\Omega} |\nabla f|^m \, dx < \varepsilon.
\]
Set
\[
Y = Y_\varepsilon = \{ y \in \mathbb{R}^m : \mathcal{L}^n(E \cap f^{-1}(y)) = 0, \, H^{n-m}(E \cap f^{-1}(y)) > a \}.
\]
Owing to the Hölder continuity of \(f\), given \(y \in Y\) we may apply Proposition 7.4 to the set \(\Omega\) and the function \(u = |f - y|\) and find a \(\delta(y) > 0\) and a compact set \(F(y) \subset \Omega\) such that \(\mathcal{L}^n(F(y)) > 0\) and
\[
\sup_{F(y)} |f(x) - y|^m < \delta(y) \leq \int_{F(y)} |\nabla f|^m \, dx.
\]
Using a Vitali type covering argument to the system of balls \( B(y, \delta(y)) \) we find disjointed balls \( B(y_j, \delta_j) \) and sets \( F_j \) such that \( y_j \in Y, \delta_j = \delta(y_j), F_j = F(y_j) \), and
\[
y \subseteq \bigcup_j B(y_j, 5\delta_j).
\]
Since the balls \( B_j \) are disjointed, the sets \( F_j \subseteq f^{-1}(B(y_j, \delta_j)) \) are also disjointed.
We infer that
\[
\mathcal{L}^m(Y) \leq \sum_j \mathcal{L}^m(B(y_j, 5\delta_j)) \leq C \sum_j \delta_j^m \leq C \sum_j \int_{F_j} |\nabla f|^m \, dx
\]
\[
\leq C \int_{\Omega} |\nabla f|^m \, dx < C\epsilon.
\]
Letting \( \epsilon \to 0 \) we obtain that \( \mathcal{L}^m(Y) = 0 \). Since \( a > 0 \) was arbitrary and the set
\[
\{ y \in \mathbb{R}^m : \mathcal{L}^n(f^{-1}(y)) > 0 \}
\]
is countable (and thus of zero \( m \)-dimensional measure), we easily conclude the proof.

\[ \Box \]

**7.2. Remark.** The proof above can be modified to give an independent proof of Theorem 1.1 when \( p > m \). Indeed, by [HM, Prop. 3.2], \( \mathcal{H}^{m-\text{a.e.}} \ z \in \mathbb{R}^n \) satisfies
\[
\limsup_{r \to 0} r^{-\beta} \int_{B(z, r)} |f(x) - f(z)| \, dx < \infty
\]
with \( \beta = 1 - \frac{m}{p} \), provided that \( f \in W^{1-p}(\mathbb{R}^n; \mathbb{R}^m) \) and \( p > m \).
Alternatively, when \( p > 1 \) one can use the fact that for \( 0 < \lambda < 1 \) and \( \epsilon > 0 \) there exists an open set \( U \) and a mapping \( g \in W^{1-p}(\mathbb{R}^n; \mathbb{R}^m) \) so that \( g \) is Hölder continuous with exponent \( \lambda \), \( f(x) = g(x) \) for all \( x \in \mathbb{R}^n \setminus U \), and \( B_{1-\lambda, p}(U) < \epsilon \), where \( B_{1-\lambda, p} \) is the Bessel capacity. See [BHS, S]: a weaker but also sufficient result of this type is given in [M1]. Thus for \( f \in W^{1-p}(\mathbb{R}^n; \mathbb{R}^m) \) there is a set \( N \) with \( B_{1-\lambda, p}(N) = 0 \) so that (1.2) holds for all \( E \subseteq \mathbb{R}^n \setminus N \). In case \( p > m \) then \( \lambda \) may be chosen so that \( \mathcal{H}^n(N) = 0 \), extending (1.2) to all measurable sets \( E \subset \mathbb{R}^n \).

**8. Further results on the graph mapping**

In this section we consider properties of the graph \( \mathcal{G}_f \) for mappings in the borderline case \( W^{1-m}(\mathbb{R}^n; \mathbb{R}^m) \), for \( 1 \leq m \leq n \). The following theorem was proved in [MM] for \( k = n \) and extended to \( k \geq n \) in [M4].

**8.1. Theorem.** Suppose that \( k \geq n \) and that \( f \in W^{1,n}_{\text{loc}}(\mathbb{R}^n; \mathbb{R}^k) \) is Hölder continuous. Then \( f \) satisfies condition (N).

We observe that mappings \( f \in W^{1-p}(\mathbb{R}^n; \mathbb{R}^k), p > n, \) satisfy the hypothesis of Theorem 3.3 and therefore this result gives a new proof of the area formula of Marcus and Mizel [MM].

We let \( G(n, m) \) denote the Grassmann manifold of \( m \)-dimensional subspaces of \( \mathbb{R}^n \). Given \( V \in G(n, m) \) let \( V^\perp \in G(n, n - m) \) denote its orthogonal complement. Writing \( x \in \mathbb{R}^n \) as \( x = x_V + x_{V^\perp} \), with \( x_V \in V \) and \( x_{V^\perp} \in V^\perp \), the orthogonal projection \( P_V : \mathbb{R}^n \to V \) is given by \( P_V(x) = x_V \). If \( V \in G(n, m) \) and \( W \in G(n, k) \), \( m + k \geq n \), observe that
\[
V^\perp \subset W \text{ if and only if } W^\perp \subset V.
\]
8.2. Proposition. If \( V \perp W \) then
1. \( P_V(W) = V \cap W \)
2. \( P_V(W + a) \cap P_V(W + b) = \emptyset \) for all \( a, b \in W^\perp, a \neq b \).

Recall that the \( n \) dimensional integral geometric measure of a set \( E \subset \mathbb{R}^{n+m} \) is given by

\[
\mathcal{I}^n(E) = \int_{G(n+m,n)} \int_V N(P_V, E, y) d\mathcal{H}^n(y) d\sigma_{n+m,n}(V),
\]

where \( N(P_V, E, y) \) is the number of points \( x \in E \) satisfying \( P_V(x) = y \), and \( \sigma_{n+m,n} \) is a normalized Haar measure on \( G(n + m, n) \). In order to prove Theorem 8.3 it suffices to show that \( \mathcal{I}^n(f(E)) = 0 \) whenever \( \mathcal{L}^n(E) = 0 \). This is a consequence of the following theorem.

8.3. Theorem. Assume that \( 1 \leq m \leq n \) and that \( f \in W^{1,m}_0(\mathbb{R}^n; \mathbb{R}^m) \) is Hölder continuous. If \( N \subset \mathbb{R}^n \) and \( \mathcal{L}^n(N) = 0 \), then \( \mathcal{H}^n(P_V \circ f(N)) = 0 \) for every \( V \in G(n + m, n) \).

Proof. Identify \( \mathbb{R}^n \) with the subspace \( \{ x \in \mathbb{R}^{n+m} : x_{n+1} = \ldots = x_{n+m} = 0 \} \) of \( \mathbb{R}^{n+m} \) and choose \( V \in G(n + m, n) \). Let \( W \in G(n + m, 2m) \) be any subspace containing \( (\mathbb{R}^n)^\perp \) and \( V^\perp \). Then \( \mathbb{R}^n \perp W \), hence \( W^\perp \subset \mathbb{R}^n \). Writing

\[
\mathbb{R}^n = (\mathbb{R}^n \cap W) \oplus (\mathbb{R}^n \cap W^\perp) = (\mathbb{R}^n \cap W) \oplus W^\perp,
\]

it follows from Proposition 8.2 that the sets \( \{ \mathbb{R}^n \cap (W + t) : t \in W^\perp \} \) are disjoint \( m \) planes in \( \mathbb{R}^n \) whose union is \( \mathbb{R}^n \). Similarly, the sets \( \{ V \cap (W + t) : t \in W^\perp \} \) are disjoint \( m \) planes in \( V \) whose union is \( V \).

For brevity we write \( W_t = W + t \). Define \( h : V \to W^\perp \) by \( h = P_{W^\perp} \circ f \). Then for \( t \in W^\perp \) we have \( h^{-1}(t) = V \cap W_t \). By the coarea formula for Lipschitz mappings between rectifiable sets [F, 3.2.22] it follows that

\[
\int_E |J_nh| d\mathcal{H}^n(x) = \int_{W^\perp} \mathcal{H}^m(E \cap W_t) d\mathcal{H}^{n-m}(t)
\]

for any \( \mathcal{H}^n \) measurable subset \( E \) of \( V \), where \( J_nh \) is the (non-zero constant) \( n \) dimensional Borel set \( A \subset \mathbb{R}^n \) we have

\[
\mathcal{H}^n(E) = J^{-1} \int_{W^\perp} \mathcal{H}^m((P_V \circ f(A)) \cap W_t) d\mathcal{H}^{n-m}(t)
\]

\[
= J^{-1} \int_{W^\perp} \mathcal{H}^m((P_V(f(A)) \cap W_t)) d\mathcal{H}^{n-m}(t)
\]

\[
\leq J^{-1} \int_{W^\perp} \mathcal{H}^m(f(A) \cap W_t)) d\mathcal{H}^{n-m}(t)
\]

by Proposition 8.2 and the fact that Hausdorff measure does not increase under orthogonal projection.

On the other hand, since \( f \in W^{1,m}_{loc}(\mathbb{R}^n; \mathbb{R}^{n+m}) \) and \( W^{1,m} \) is invariant under any nonsingular linear change of coordinates, Fubini’s theorem implies that

\[
(8.1) \quad \hat{f}_t := \hat{f}_{|\mathbb{R}^n \cap W_t} \in W^{1,m}_{loc}(\mathbb{R}^n \cap W_t; \mathbb{R}^{n+m})
\]
for $\mathcal{H}^{n-m}$ almost all $t \in W^\perp$. Since $m = \dim(\mathbb{R}^n \cap W_t)$, Theorem 8.1 above implies that

$$\mathcal{H}^m(\bar{f}_t(A)) = \int_{A \cap W_t} |J_m \bar{f}_t(x)| d\mathcal{H}^m(x)$$

for $\mathcal{H}^{n-m}$ almost all $t \in W^\perp$ whenever $A \subset \mathbb{R}^n$ is Lebesgue measurable and where $J_m \bar{f}_t$ is the $m$ dimensional Jacobian of $\bar{f}_t$. Proposition 8.2 implies that $\bar{f}_t(E) = \bar{f}(E) \cap W_t$, hence for all such $t$ we have

$$\mathcal{H}^m(\bar{f}(A) \cap W_t) = \int_{A \cap W_t} |J_m \bar{f}_t(x)| d\mathcal{H}^m(x).$$

To complete the argument let $N \subset \mathbb{R}^n$ be a set with Lebesgue measure zero and let $A \subset \mathbb{R}^n$ be a Borel set containing $N$ with Lebesgue measure zero. Fubini’s theorem implies that $\mathcal{H}^m(A \cap W_t) = 0$ for $\mathcal{H}^{n-m}$ almost all $t \in W^\perp$, and therefore

$$\mathcal{H}^m(\bar{f}(A) \cap W_t) = 0$$

for all such $t$. It follows that

$$\mathcal{H}^n(P_V \circ \bar{f}(N)) \leq \mathcal{H}^n(P_V \circ \bar{f}(A)) \leq J^{-1} \int_{W^\perp} \mathcal{H}^m(\bar{f}(A) \cap W_t) d\mathcal{H}^{n-m}(t) = 0,$$

establishing the lemma.

This result is not sufficient to conclude that $\mathcal{H}^n(\bar{f}(N)) = 0$, since there exist sets of positive Hausdorff measure whose projection in every direction has zero measure, cf. [M] [Example 9.2]. However, with the help of [M, Corollary 9.8] and [F3, 3.2.27] we arrive at the following.

**8.4. Corollary.** With $f$ and $N$ as in the proof of Theorem 8.3, $\mathcal{I}^n(\bar{f}(N)) = 0$. In particular, the Hausdorff dimension of $\bar{f}(N)$ does not exceed $n$. Moreover, either $\mathcal{H}^n(\bar{f}(N)) = 0$ or $\bar{f}(N)$ is purely $\mathcal{H}^n$ unrectifiable.
