Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Safety and immunogenicity of an inactivated COVID-19 vaccine, BBIBP-CorV, in people younger than 18 years: a randomised, double-blind, controlled, phase 1/2 trial

ShengLi Xia, YunTai Zhang, YanXia Wang, Hui Wang, YunKai Yang, George Fu Gao, Wenjie Tan, GuiZhen Wu, Miao Xu, ZhiYong Lou, Weijin Huang, WenBo Xu, BaoYing Huang, Wei Wang, Wei Zhang, Na Li, ZhiQiang Xie, Xiujuan Zhu, Ling Ding, WangYang You, YuXiu Zhao, Jun Zhao, LiLi Huang, XueZhang Shi, YongLi Yang, GuangXue Xu, WenLing Wang, PeiPei Liu, Meng Ma, YuLing Qiao, SuHua Zhao, JingLing Chai, QinQin Li, Hui Fu, Ying Xu, XiaoTong Zheng, WanShen Guo, XiaoMing Yang

Summary

Although SARS-CoV-2 infection often causes milder symptoms in children and adolescents, young people might still play a key part in SARS-CoV-2 transmission. An efficacious vaccine for children and adolescents could therefore assist pandemic control. For further evaluation of the inactivated COVID-19 vaccine candidate BBIBP-CorV, we assessed the safety and immunogenicity of BBIBP-CorV in participants aged 3–17 years.

Methods

A randomised, double-blind, controlled, phase 1/2 trial was done at Shangqiu City Liangyuan District Center for Disease Control and Prevention in Henan, China. In phases 1 and 2, healthy participants were stratified according to age (3–5 years, 6–12 years, or 13–17 years) and dose group. Individuals with a history of SARS-CoV-2 or SARS-CoV infection were excluded. All participants were randomly assigned, using stratified block randomisation (block size eight), to receive three doses of 2 μg, 4 μg, or 8 μg of vaccine or control (1:1:1:1) 28 days apart. The primary outcome, safety, was analysed in the safety set, which consisted of participants who had received at least one vaccination after being randomly assigned, and had any safety evaluation information. The secondary outcomes were geometric mean titre (GMT) of the neutralising antibody against infectious SARS-CoV-2 and were analysed based on the full analysis set. This study is registered with www.chictr.org.cn, ChiCTR2000032459, and is ongoing.

Findings

Between Aug 14, 2020, and Sept 24, 2020, 445 participants were screened, and 288 eligible participants were randomly assigned to vaccine (n=216, 24 for each dose level [2/4/8 μg] in each of three age cohorts [3–5, 6–12, and 13–17 years]) or control (n=72, 24 for each age cohort [3–5, 6–12, and 13–17 years]) in phase 1. In phase 2, 810 participants were screened and 720 eligible participants were randomly assigned and allocated to vaccine (n=540, 60 for each dose level [2/4/8 μg] in each of three age cohorts [3–5, 6–12, and 13–17 years]) or control (n=180, 60 for each age cohort [3–5, 6–12, and 13–17 years]). The most common injection site adverse reaction was pain (ten [4%] 251 participants in all vaccination groups and eight [9·5%] of 84 in the control group of the 13–17 years cohort). The most common systematic adverse reaction was fever (32 [12·7%] of 251 participants in all vaccination groups and two [1·2%] of 252 participants in all vaccination groups of the 13–17 years cohort). The most common common adverse reaction was fever (32 [12·7%] of 251 participants in all vaccination groups and eight [9·5%] of 84 in the control group of the 13–17 years cohort). Adverse reactions were mostly mild to moderate in severity. The neutralising antibody GMT against the SARS-CoV-2 virus ranged from 105·3 to 180·2 in the 3–5 years cohort, 84·1 to 168·6 in the 6–12 years cohort, and 88·0 to 155·7 in the 13–17 years cohort. reverse reactions were mostly mild to moderate in severity. The neutralising antibody GMT against the SARS-CoV-2 virus ranged from 105·3 to 180·2 in the 3–5 years cohort, 84·1 to 168·6 in the 6–12 years cohort, and 88·0 to 155·7 in the 13–17 years cohort. On day 28 after the second vaccination; and ranged from 143·5 to 224·4 in the 3–5 years cohort, 127 to 184·8 in the 6–12 years cohort, and 105·3 to 180·2 in the 3–5 years cohort, 84·1 to 168·6 in the 6–12 years cohort, and 88·0 to 155·7 in the 13–17 years cohort. On day 28 after the second vaccination; and ranged from 143·5 to 224·4 in the 3–5 years cohort, 127 to 184·8 in the 6–12 years cohort, and 105·3 to 180·2 in the 3–5 years cohort, 84·1 to 168·6 in the 6–12 years cohort, and 88·0 to 155·7 in the 13–17 years cohort. On day 28 after the second vaccination; and ranged from 143·5 to 224·4 in the 3–5 years cohort, 127 to 184·8 in the 6–12 years cohort, and 105·3 to 180·2 in the 3–5 years cohort, 84·1 to 168·6 in the 6–12 years cohort, and 88·0 to 155·7 in the 13–17 years cohort.

Interpretation

The inactivated COVID-19 vaccine BBIBP-CorV is safe and well tolerated at all tested dose levels in participants aged 3–17 years. BBIBP-CorV also elicited robust humoral responses against SARS-CoV-2 infection after two doses. Our findings support the use of a 4 μg dose and two-shot regimen BBIBP-CorV in phase 3 trials in the population younger than 18 years to further ascertain its safety and protection efficacy against COVID-19.

Introduction

According to WHO, as of July, 2021, the COVID-19 pandemic has caused more than 4 million deaths worldwide. Children are susceptible to SARS-CoV-2 infection, but show milder clinical manifestation of disease. This susceptibility raises the possibility of...
transmission among family members, and risk to elderly members who are more vulnerable to disease. Clinical trials of vaccine candidates on different platforms (inactivated, protein subunit, mRNA, and vector based) have shown their safety and efficacy against SARS-CoV-2 in adults, but to date fewer studies have been done in children. An mRNA vaccine candidate BNT162b2 (tozinameran; Pfizer–BioNTech) has shown 100% efficacy in a population aged 12–25 years. Another mRNA vaccine candidate mRNA-1273 (Moderna, Cambridge, MA, USA) is reported to be tolerated and to have efficacy against COVID-19 of 100% starting 14 days after the second dose in adolescents aged 12–17 years. The safety and immunogenicity of the inactivated vaccine CoronaVac (Sinovac, Beijing, China) is being tested in a phase 1/2 trial in a population aged 3–17 years. In addition to CoronaVac, further evaluation of safety and immunogenicity of the inactivated COVID-19 vaccine BBIBP-CorV (Beijing Institute of Biological Products, Beijing, China) is needed in populations aged younger than 18 years.

Our previous phase 1/2 clinical trial interim report of BBIBP-CorV, has shown an acceptable safety profile and immunogenicity in participants aged 18–59 years and 60 years and older. Thus, in this study, we further report the full set of safety and immunogenicity data for BBIBP-CorV in phase 1 and 2 clinical trials among healthy people younger than 18 years in China.

Methods
Study design and participants
We did a randomised, double-blind, dose-escalation, controlled phase 1/2 trial of BBIBP-CorV in the Shangqiu City Liangyuan District Center for Disease Control and Prevention in Henan, China. The enrolled participants were healthy individuals aged 3–17 years, who were negative for serum-specific IgM or IgG antibodies against SARS-CoV-2 N and S proteins (tested and verified with a commercial kit from Innovita, China) at the time of screening and vaccine inoculation on the same day. Exclusion criteria were a history of travelling to Hubei, regions outside of China, or regions within China with any reported COVID-19 cases since December, 2019; a history of infection with SARS-CoV; fever (axillary temperature more than 37.3°C if aged older than 14 years, and axillary temperature of more than 37.5°C if aged 14 years or younger), respiratory syndromes, diarrhoea, dyspnoea, or tachypnoea within 14 days before vaccination; abnormal results in laboratory tests (blood biochemistry tests [alanine aminotransferase, aspartate aminotransferase, total bilirubin, creatinine, urea nitrogen], routine blood tests [haemoglobin, white blood cell count], and routine urine tests [protein, urine sugar, blood cells—microscopic examination]); allergy to any ingredient included in a vaccine; a history of seizures or mental illness (defined as a history of convulsion, epilepsy or psychosis); and being unable to comply with the study schedule. Criteria for early suspension of trial are outlined in the protocol (ChiCTR2000032459). Safety was reviewed by a safety monitoring board before proceeding to the next dose group or next age cohort, and for advancement to phase 2.

The trial design was a dose escalation study, in three dose levels (2 μg, 4 μg, and 8 μg per dose) at a 28-day intervals in both adults and children. After an interim analysis showed BBIBP-CorV’s safety and immunogenicity in an adult population after two doses of vaccines; the adult cohort continued on to receive the third dose of vaccine. These data were obtained according to the original trial protocol. The studies of individuals aged 3–17 years were also done using a three-dose regimen, according to the original protocol.

The protocol and informed consent were approved by the Medical Ethics Committee of Henan Provincial Center for Disease Control and Prevention. Written informed consent from all participants was obtained before screening. This study was done by Henan Institute of Biological Products, Beijing, China.)

Evidence before this study
We searched PubMed for research articles published from database inception until April 20, 2021, using the terms “COVID-19” OR “SARS-CoV-2”, “vaccine”, AND “clinical trial” AND “phase”. Article type was set to clinical trial. No language and date restrictions were applied. 34 reports were identified, among which five were for inactivated vaccines, two were for spike protein subunit vaccines, seven were for mRNA vaccines, and eight were for vector-based vaccines. We identified one clinical trial report for the SARS-CoV-2 mRNA vaccine candidate BNT162b2 done in children and adolescents by the time our Article was under revision. On May 25, 2021, Moderna announced that the phase 2/3 study of its mRNA vaccine candidate mRNA-1273 in adolescents had met its primary immunogenicity endpoint.

Added value of this study
The present trial showed that the inactivated COVID-19 vaccine, BBIBP-CorV, was safe and able to elicit a robust humoral response in healthy people younger than 18 years. Seroconversion rate of neutralising antibody was found in all vaccinees on day 28, and the neutralising antibody geometric mean titre was at level comparable to that of adults in earlier trials.

Implications of all the available evidence
Our finding indicates that BBIBP-CorV is safe and immunogenic in healthy individuals aged 3–17 years. Further clinical investigation is needed to evaluate the efficacy of this vaccine candidate for prevention of COVID-19 in the general population.
Provincial Center for Disease Control and Prevention, and implemented in Liangyuan, Shangqiu, in accordance with the Declaration of Helsinki and Good Clinical Practice.

Randomisation and masking
In age de-escalation, dose escalation phase 1 and 2 studies, participants were stratified by age (3–5 years, 6–12 years, or 13–17 years) and were randomly assigned to receive intramuscular injections of 2 µg, 4 µg, 8 µg, or control (1:1:1:1). Within each dose-escalating group of each age cohort in phase 1/2, the ratio of vaccine versus control was 3:1. Participants were sequentially assigned a randomisation number generated by an independent statistician using Stata, version 12.0, and stratified block randomisation (block size eight) by subgroups was adopted. All vaccines used for inoculation were distributed in identical packages with serial numbers to ensure masking of participants. The safety evaluation was masked for all participants. Group allocation was masked from participants, investigators, and outcome assessors for the duration of the study.

Procedures
BBIBP-CorV was developed by Beijing Institute of Biological Products (Beijing, China), and manufactured as previously described. Briefly, the strain 19nCoV-CDC-Tan-HB02 (HB02), with optimal replication and highest virus yields in Vero cells, was inactivated by β-propionolactone at a ratio of 1:4000 at 2–8°C. The vaccine was manufactured as a liquid formulation containing 2 µg, 4 µg, or 8 µg of total proteins with aluminium hydroxide adjuvant (0.45 mg/mL) per 0.5 mL in a vial. The control consisted of saline and aluminium hydroxide adjuvant.

In phase 1 and 2, participants in the three groups (3–5 years, 6–12 years, and 13–17 years) received 2 µg, 4 µg, or 8 µg of BBIBP-CorV or control on a three-dose schedule (on days 0, 28, and 56).

For safety assessments, all adverse reactions, including solicited and unsolicited adverse events, from the first dose to 30 days after the full course of vaccinations were collected by the investigator’s active visits and spontaneous reports. The investigators had phone calls or face-to-face interviews within 7 days after each dose, and weekly phone calls 8–30 days after each dose. Laboratory safety values (haematology, serum, and chemistry) were measured before vaccination (baseline) and on day 4 after each vaccination. The adverse events and abnormal changes in laboratory test results were graded according to the scales issued by the China State Food and Drug Administration. Safety data were collected based on guidance issued by the National Medical Products Administration, and monitored by the data safety monitoring board on 8 days after the first vaccination and 30 days after the vaccination schedule had been completed.

Blood samples were collected for serology tests at the scheduled site visits before each vaccination (days 0, 28, and 56), and on day 84. The neutralising antibody responses induced by vaccination were determined by microneutralisation assay with the infectious SARS-CoV-2 virus (strain 19nCoV-CDC-Tan-Strain05, QD01). Serum was diluted 1/4, followed by a series of two-times dilutions to the required concentration, and an equal volume of challenge virus solution was added. After neutralisation in a 37°C incubator for 2 h, a 1·0–2·5 × 10⁵ cells per mL suspension was added to the wells of a 96-well plate (0.1 mL per well) and cultured in a CO₂ incubator at 37°C for 4 days. Titres were expressed as the reciprocal of the highest dilution level protecting 50% cells from virus challenge. Human convalescent serum (HCS) was collected from patients at least 15 days after confirmation of SARS-CoV-2 infection. HCS was included as an internal positive control in every assay. Seroconversion was defined as a four-times increase in antibody titre relative to day 0.

Outcomes
The primary outcome for safety was the occurrence of adverse reactions within 7 days after each vaccination. Any abnormal changes in laboratory test results were measured on day 4 after each vaccination, and adverse reactions within 30 days after whole vaccination procedure across all study groups were analysed as secondary safety endpoints. The secondary outcomes for humoral immunogenicity were measured with infectious SARS-CoV-2 neutralising assay (on days 0, 28, 56, and 84) and expressed as neutralising antibody geometric mean titres (GMTs) and seroconversion.

Statistical analysis
The sample size was not determined based on the statistical power calculation. Both phases were designed at the same time. For a sample size of 84 in 2 µg, 4 µg, and 8 µg of each age subgroup (24 in phase 1 and 60 in phase 2), we had an 80% test power to detect a 15% rate difference in immunogenicity with 10% dropout at a 0.05 significance level using a Z test for two independent proportions in PASS13-NCSS10. This result in a planned sample sizes of 24 participants for each vaccination group and eight for each control group in phase 1, and 60 participants for each vaccination group and 20 for each control group in phase 2 were determined.

The safety analysis was based on the safety set, which consisted of participants who had received at least one vaccination after being randomly assigned, and had any safety evaluation information. Humoral immunogenicity analysis was based on the full analysis set, which consisted of enrolled participants who had randomly received a vaccination with blood collection before and after each inoculation, and the compliance set, which consisted of enrolled participants who had randomly
received a vaccination with blood sample collection before and after each inoculation and showed no trial protocol violation. From the perspective of trial design, vaccination:control ratio was 3:1 inside the dose-escalating group of each age cohort. The analysis was done by comparing the vaccination group with control within the same dose-escalating group.

Data from phases 1 and 2 were pooled for analysis, since the participants in both studies had similar characteristics and underwent same vaccination regimens and the safety and immunogenicity data of two phases should thus be theoretically comparable. No formal statistical analysis was planned for unsolicited adverse events. The occurrence of laboratory abnormalities was tested by χ² test, correction χ² test, or Fisher’s exact test between the test group and the control group in each age cohort, among groups who received different doses. GMTs for neutralising antibody with corresponding 95% CIs are reported. Comparison of antibody titres at timepoints after immunisation was done with the two independent sample t tests (normal and homogeneous variance) or corrected t tests (normal but non-homogeneous variance). For abnormally distributed data, a Wilcoxon rank sum test was used to compare the difference between experimental and control groups of different ages, among groups who received different doses. All data were included in the analyses. All analyses were done using GraphPad Prism (version 8.0.1). All statistical tests were two-sided, and the significance level was p values of 0·05 or less for inferential analyses and multiple comparisons were not adjusted.

Role of the funding source
The funders of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the report. All authors had full access to all the data in the study and had final responsibility for the decision to submit for publication.

Results
Between Aug 14, 2020, and Sept 24, 2020, 445 participants were screened, and 288 eligible participants were randomly assigned to vaccine or control in the phase 1 study. Enrolled participants were evenly distributed over three age cohorts (3–5 years, 6–12 years, and 13–17 years). Each participant received three shots of either vaccine (at 2 μg, 4 μg, or 8 μg) or control at 28-day intervals. All 288 participants received the first vaccination on day 0, and all but four received the second vaccination on day 28 and the third vaccination on day 56. Exceptions included three participants in the 4 μg 3–5 years cohort and one participant in the 4 μg 6–12 years cohort (figure 1). In phase 2, 810 participants were screened and 720 eligible participants were randomly assigned and allocated to vaccine or control. Enrolled participants were evenly distributed over three age groups (3–5 years, 6–12 years, and 13–17 years). Participants in phase 2 underwent identical vaccination procedures to the phase 1 study. All but one of the 720 participants received the first vaccination on day 0, and all but seven received the second vaccination on day 28 and the third vaccination on day 56 (figure 1). Exceptions included one participant in the 2 μg 3–5 years cohort, one participant in the 8 μg 3–5 years cohort, one participant in the 2 μg 6–12 years cohort, one participant in the 8 μg 6–12 years cohort, and three participants in the 4 μg 13–17 years cohort. All withdrawals were requested by participants or their guardian. Detailed demographic characteristics of the participants are listed in tables 1 and 2.

The most common adverse reaction was pain at the injection site, which was reported within 30 days after all three vaccinations by ten (4·0%) of 251 participants in the vaccination groups of the 3–5 years cohort, 23 (9·1%) of 252 participants in the vaccination groups and one (1·2%) of 84 participants in the control group of the 6–12 years cohort, and 20 (7·9%) of 252 participants in the vaccination groups of the 13–17 years cohort (tables 2–4; appendix 2 p 1). Participants in the vaccine groups in the 6–12 years (p=0·014) and 13–17 years (p=0·0078) cohorts reported significantly more pain than participants in the control groups. A dose-dependent increase in overall injection site adverse reactions in the vaccine groups compared with the control group was detectable in the 6–12 years cohort (table 5; appendix 2 p 1). Reported local adverse reactions were all mild (grade 1) and moderate (grade 2) in severity.

The most common systemic reactions reported after each vaccination in all three age cohorts were mild to moderate fever and cough. After the vaccination schedule was completed, fever was reported by 32 (12·7%) of 252 participants in all three dose groups, and by six (7·1%) of 84 participants in the control group of the 3–5 years cohort; 13 (5·2%) of 251 participants in all three dose groups, and one (1·2%) of 84 participants in the control group of the 6–12 years cohort; and 20 (10·3%) of 252 participants in all three dose groups, and eight (9·5%) of 84 participants in the control group of the 13–17 years cohort (table 3–4; appendix 2 p 1). The frequency of fever was lower after the second and third doses compared with the first dose (appendix 2 pp 2–10). The second most common systematic reaction was cough, and no signs of upper respiratory tract infection were detected during follow-up. Cough was reported by 22 (8·7%) of 252 participants in the vaccination groups and nine (10·7%) of 84 participants in the control group of the 3–5 years cohort; eight (3·2%) of 252 participants in the vaccination groups and one (1·2%) of 84 participants in the control group of the 6–12 years cohort; and 26 (10·3%) of 252 participants in all three dose groups, and eight (9·5%) of 84 participants in the control group of the 13–17 years cohort (table 3–4; appendix 2 p 1).
group compared with the control group was detectable independent of dose level in the 13–17 years cohort (table 5; appendix 2 p 1). There was one grade 3 systematic acute allergic reaction reported 4 days after the second vaccination in the 2 μg group of 6–12 years cohort. Laboratory abnormalities were mild to moderate in severity after each vaccination dose. Elevated white blood cell count (reference range $4–10 \times 10^9$ cells per L) occurred in the 3–5 years cohort (17 [23·6% of 72 in the vaccination group and six [25·0%] of 24] in the control group) and the 6–12 years cohort (11 [15·3%] of 72 in the vaccination group and five [20·8%] of 24 in the control group). The 13–17 years cohort reported fewer elevated white blood cell counts (two [2·8%] of 72 in the vaccination group and two [8·3%] of 24 in the control group). An additional haemoglobin abnormality was observed in the 13–17 years cohort (seven [9·7%] of 72 in the vaccination group and one [4·2%] of 24 in the control group). Laboratory abnormalities of grade 3 were all white blood cell count value changes, and were reported in the 3–5 years 2 μg group (two [2·8%] of 72) and 6–12 years 4 μg group (one [1·4%] of 72). Grade 3

(Figure 1 continues on next page)
laboratory abnormalities were transient (ie, resolved within 10 days).

One vaccine-related unsolicited adverse event (grade 3 allergic purpura) was reported after the second dose of 2 μg in the cohort aged 6–12 years. Throughout the course of hospitalisation, this participant was diagnosed as allergic and intolerant to a variety of food allergens. This participant made a complete recovery after a 5-day hospitalisation, but withdrew from the third dose vaccination and is still under follow-up monitoring due to safety concerns.

Neutralising antibody titres against infectious SARS-CoV-2 were assessed 28 days after every vaccination (days 0, 28, 56, and 84). Neutralising antibodies for all participants were tested negative before vaccination as a requirement of the enrolment and remained negative throughout the studies in the control groups.

In the cohort aged 3–5 years, 61 (75%) of 81 participants in the 2 μg group, 75 (90%) of 83 participants in the 4 μg group, and 75 (91%) of 82 participants in the 8 μg group were seroconverted on day 28 (figure 2). In the cohort aged 6–12 years, 80 (95%) of 84 participants in the 2 μg group,

Data are n (%). Any refers to all participants with any grade adverse reactions or reactions. Adverse reactions and reactions were graded according to the scale issued by the China State Food and Drug Administration. Grade 1 is mild, grade 2 is moderate, and grade 3 is severe.
all 84 (100%) participants in the 4 μg group, and all 83 (100%) participants in the 8 μg group were seroconverted on day 28 (figure 2). In the cohort aged 13–17 years, all 83 (100%) participants in the 2 μg group, 82 (99%) of 83 participants in the 4 μg group, and all 82 (100%) participants in the 8 μg group were seroconverted on day 28 (figure 2). Seroconversion rates reached 100% on day 56 in all three dose levels of all three age cohorts.

| Overall adverse reactions after whole vaccination procedure dose

Data are n (%). Any refers to all the participants with any grade adverse reactions or reactions. Adverse reactions and reactions were graded according to the scale issued by the China State Food and Drug Administration. Grade 1 is mild, grade 2 is moderate, and grade 3 is severe.

Table 5: Adverse reactions within 30 days after whole vaccination procedure for group aged 13-17 years
Dose-level dependent immunogenicity was observed on day 56 (28 days after the second vaccination) in all three age cohorts. The 4 μg and 8 μg groups showed significantly higher antibody response compared with the 2 μg group (appendix pp 16, 20, 24).

In the cohort aged 3–5 years, the neutralising antibody of all three dose levels were detectable on day 28, at a GMT of 14·5 (95% CI 11·2–18·7) in the 2 μg group, 20·2 (16·3–25·0) in the 4 μg group, and 21·3 (17·5–26·0) in the 8 μg group. By day 28, there were no significant differences in neutralising antibody GMT among the 2 μg (p=0·50), 4 μg (p=0·80), and 8 μg (p=0·85) groups. By day 56 (28 days after the second vaccination), the neutralising antibody GMT increased to 105·3 (95% CI 95·4–116·2) in the 2 μg group, 180·2 (163·4–198·8) in the 4 μg group, and 170·8 (152·2–189·1) in the 8 μg group. The 2 μg group neutralising antibody GMT was significantly lower than that of the 4 μg (p<0·001) and 8 μg (p<0·001) groups, while no significant difference in neutralising antibody GMT between the 4 μg group and 8 μg group was observed (p=0·71). By day 84 (28 days after the third vaccination), the 2 μg group neutralising antibody GMT was significantly lower than that of the 4 μg (p=0·0018) and 8 μg (p=0·0013) groups, and no significant difference in neutralising antibody GMT was detected between the 4 μg and 8 μg groups (p=0·85; figure 2; appendix 1 pp 14–17).

Unlike the 3–5 years cohort, the neutralising antibody GMT of the 2 μg group in both the 6–12 years (p=0·001) and 13–17 years (p=0·0053) groups significantly differed to that of the 4 μg (p<0·001) and 8 μg (p<0·001) groups within same age cohort on day 28. Neutralising antibody GMTs of the 4 μg and 8 μg groups in the cohorts aged 6–12 years (p=0·80) and 13–17 years (p=0·53) were comparable at day 56 (figure 2; appendix 2 pp 18–24).

All dose levels across all age cohorts showed comparable neutralising antibody GMTs compared with HCS (198·0, 95% CI 250·2–146·7) on day 84, except the 2 μg group in the 6–12 years cohort, which showed significantly lower
neutralising antibody GMT (127·0, 95% CI 144·2–111·8; p=0·02) compared with HCS on day 84.

Discussion
In this phase 1/2 clinical trial of participants younger than 18 years, the three-dose regimen of 2 μg, 4 μg, and 8 μg of BBIBP-CorV inactivated vaccine had an acceptable safety profile, and was able to elicit robust humoral response against SARS-CoV-2.

Local and systemic adverse reactions were mostly mild to moderate in severity. Adverse reactions occurred predominantly after the first dose and showed similar frequency after the first vaccination in participants aged 3–17 years and participants aged 18–59 years or 60 years or older. The most common adverse reactions were pain and fever, which were transient or resolved in few days. There were three grade 3 white blood cell count abnormal changes in the vaccination group, but all were clinically insignificant.

One unsolicited adverse event was reported in the 2 μg group in the cohort aged 6–12 years during phase 2 study. This participant was later diagnosed as being allergic to various food allergens, but considering this adverse event occurred on the second day after the second vaccination dose, we recorded it as an adverse event possibly related to the vaccine. Therefore, in future studies, more attention should be paid to vaccinees with a history of allergy, and more safety data for large-scale clinical or post-marketing application are needed.

The BBIBP-CorV inactivated vaccine was immunogenic and induced robust humoral responses, with the seroconversion ratio of 100% in all vaccination groups. By day 56 (28 days after the second vaccination), the neutralising antibody elicited by BBIBP-CorV ranged from 105·3 to 180·2 in the cohort aged 3–5 years, 84·1 to 168·6 in the cohort aged 6–12 years, and 88·0 to 155·7 in the cohort aged 13–17 years, which were similar to the BBIBP-CorV-elicited antibody level in adult participants (figure 2). We found a lower seroconversion rate and lower neutralising antibody titre on day 28 in the cohort aged 3–5 years than that of other age cohorts. Lower antibody response after the first vaccination was also observed in the cohort aged 60 years and older in our previous study. We reason the lower neutralising antibody responses might be caused by undertraced or atrophy of the immune system of younger children (3–5 years) or older individuals (≥60 years).  

A report of a phase 1/2/3 study of BNT162b2 has shown its safety and 100% efficacy in individuals aged 12–25 years. Another mRNA vaccine candidate, mRNA-1273, is reported to be tolerated and to have efficacy against COVID-19 of 100%, starting 14 days after the second dose, in children aged 12–17 years. Efforts are also being made to further evaluate safety, immunogenicity, and efficacy of mRNA vaccines (NCT04816643, NCT04649151, and NCT04796896) or an inactivated vaccine in s population younger than 12 years. These clinical trials, along with ours, will further address the feasibility of safe and efficacious vaccines in preventing disease in children and adolescents.

There are several limitations of our clinical trial, including: a short duration of follow-up (84 days), safety profile, and need for a longer follow-up period to evaluate antibody persistence; participants had limited racial and ethnic diversity as compared with the general population; cellular immunity elicited by BBIBP-CorV, especially T-cell response, was not evaluated (planned for follow-up studies); an absence of data for cross-protection efficacy of neutralising antibody elicited in the cohort aged 3–17 years against newly emerged variants (eg, B.1.1.720 and B.1.61721); and the neutralising antibody elicited by BBIBP-CorV could inhibit SARS-CoV-2 infection in cell culture, but the protection efficacy in people younger than 18 years is unknown. Although phase 3 studies of two inactivated SARS-CoV-2 vaccine candidates (BBIBP-CorV and CoronaVac) have demonstrated their efficacies in a general population of adults, an efficacy study of BBIBP-CorV in people younger than 18 years is necessary. An immune-bridging phase 3 study is planned for populations aged 3–17 years and 18 years and older using the 4 μg dose, with a two-shot regimen 21 days apart for additional safety data, immunogenicity, and efficacy; the trial will be done in the UAE. Additionally, although we included HCS as internal positive control in every assay, there was still no standardised HCS authorised by WHO with a universal distribution of donor characteristics (eg, disease severity and collection timing).

In conclusion, we found that the inactivated COVID-19 vaccine BBIBP-CorV is tolerable and immunogenic in individuals aged 3–17 years. Humoral responses against SARS-CoV-2 were elicited after the first inoculation of the vaccine and 100% seroconversion was achieved in all participants by day 56. These findings support the evaluation of this vaccine candidate in phase 3 trials with populations aged 3–17 years to further ascertain its safety and protection efficacy against SARS-CoV-2.

Contributors
The study was designed by SLX, YTZ, YKY, and YXW. XMY and WSG provided regulatory oversight. WW provided project management. WZ, ZQX, WYY, and LLH collected study data and oversaw participant visits. Safety data analysis and interpretation were done by JZ, XZS, GXX, YX, and HF. Immunogenicity testing was done by BYH, PPL, MM, YLQ, SHZ, JJC, QQL, WLT, and XJT. Immunogenicity data collected and analysed by YLY, NI, LD, YXZ, and XJZ, and was interpreted by GFG, HW, WBX, GZW, WJT, MX, and WJH. GXX and ZYL wrote the manuscript. Data were accessed and verified by YXW, YLY and WW. All authors contributed to the reviewing and editing of the report and approved the final version.

Declaration of interests
XMY, YTZ, YKY, HW, WW, NI, XJZ, LD, YXZ, JZ, MM, YLQ, SHZ, JJC, QQL, HF, YX, and XJT are employees of Beijing Institute of Biological Products, which developed the vaccine and funded the trial. All other authors declare no competing interests.

Data sharing
We support data sharing of the individual participant data. The individual participant data that underlie the results reported in this Article, after de-identification (ie, text, tables, figures, and appendix 2) will be shared.
Individual participant data will be available beginning 3 months and ending 1 year after publication. Supporting clinical documents, including the study protocol, statistical analysis plan, and the informed consent form, will be available immediately after publication for at least 1 year. Researchers who provide a scientifically sound proposal will be allowed access to the individual participant data. Proposals should be directed to wangyanxia99@163.com or rwsichinicaltrials@163.com. These proposals will be reviewed and approved by the funder, investigator, and collaborators on the basis of scientific merit. To gain access, data requesters will need to sign a data access agreement.
