Abstract

O-GlcNAcylation (addition of N-acetyl-glucosamine on serine or threonine residues) is a post-translational modification that regulates stability, activity or localization of cytosolic and nuclear proteins. O-linked N-acetylglucosamine transferase (OGT) uses UDP-GlcNAc, produced in the hexosamine biosynthetic pathway to O-GlcNaclylate proteins. Removal of O-GlcNAc from proteins is catalyzed by the β-N-Acetylglucosaminidase (OGA). Recent evidences suggest that O-GlcNAcylation may affect the growth of cancer cells. However, the consequences of O-GlcNAcylation on anti-cancer therapy have not been evaluated. In this work, we studied the effects of O-GlcNAcylation on tamoxifen-induced cell death in the breast cancer-derived MCF-7 cells. Treatments that increase O-GlcNAcylation (PUGNAc and/or glucosamine) protected MCF-7 cells from death induced by tamoxifen. In contrast, inhibition of OGT expression by siRNA potentiated the effect of tamoxifen on cell death. Since the PI-3 kinase/Akt pathway is a major regulator of cell survival, we used BRET to evaluate the effect of PUGNAc +glucosamine on PI3K production. We observed that these treatments stimulated PI3K production in MCF-7 cells. This effect was associated with an increase in Akt phosphorylation. However, the PI-3 kinase inhibitor LY294002, which abolished the effect of PUGNAc+glucosamine on Akt phosphorylation, did not impair the protective effects of PUGNAc+glucosamine against tamoxifen-induced cell death. These results suggest that the protective effects of O-GlcNAcylation are independent of the PI-3 kinase/Akt pathway. As tamoxifen sensitivity depends on the estrogen receptor (ERα) expression level, we evaluated the effect of PUGNAc+glucosamine on the expression of this receptor. We observed that O-GlcNAcylation-inducing treatment significantly reduced the expression of ERα mRNA and protein, suggesting a potential mechanism for the decreased tamoxifen sensitivity induced by these treatments. Therefore, our results suggest that inhibition of O-GlcNAcylation may constitute an interesting approach to improve the sensitivity of breast cancer to anti-estrogen therapy.

Introduction

Growth and proliferation of cancer cells tightly depend on their nutritional environment, particularly on glucose availability, which is necessary for increased biosynthesis of cellular components associated with proliferation (e.g. membranes, proteins and nucleic acids) [1]. Nutritional and metabolic conditions are known to influence tumour development. Excess food intake associated with modern lifestyle constitutes an important cancer risk factor [2]. In animals, food restriction has inhibitory effects on the growth of certain tumours [3], whereas in diet-induced obesity models, overfeeding is associated with accelerated development of tumours [4].

Nutritional conditions can modulate tumour development by modifying insulin and IGF-1 concentrations, which affect signalling pathways involved in cell growth, proliferation and apoptosis. However, at the cellular level, glucose can also directly regulate signalling pathways and multiple biological processes through O-GlcNAc glycosylation (O-GlcNAcylation) of cytosolic and nuclear proteins [5]. O-GlcNAcylation is a
reversible post-translational modification, analogous to phosphorylation, which controls protein localisation, stability or activity according to the nutritional environment. It corresponds to the addition of N-Acetylglucosamine (GlcNAc) on serine or threonine residues. This reaction is catalysed by O-GlcNAc transferase (OGT), which uses UDP-GlcNAc as a substrate (Figure 1). UDP-GlcNAc, produced through the hexosamine biosynthetic pathway (HBP), can be considered as a sensor for the nutritional state of the cell, as it integrates glucose, glutamine, fatty acids (acetyl), uridine and ATP metabolism [5–9]. O-GlcNAc is rapidly removed from proteins by O-GlcNAcase (OGA), permitting dynamic regulation of O-GlcNAcylation levels in cells.

A growing amount of studies indicates that O-GlcNAcylation constitutes an important regulator of cancer growth and invasion. A number of transcription factors involved in the control of cell proliferation or cell death can be regulated by O-GlcNAc [10–15]. Moreover, increased protein O-GlcNAcylation has been detected in cells derived from breast, lung, colon, liver and prostate cancers. These modifications, often associated with changes in OGT and/or OGA levels [16–18], favour the growth and/or migration of tumour cells through
different mechanisms, including regulation of transcription factors activity [19,20], E-cadherin [18,21], and MMP metalloproteases [18,20].

Breast cancer is the most common cancer in women. Endocrine therapies have permitted important progress for the treatment of hormone-sensitive breast cancers. However, the development of treatment resistance constitutes an important limitation to these therapies. Thus, tamoxifen, a partial antagonist of the estrogen receptor, has been largely used for the treatment of estrogen receptor positive breast cancers, but resistance to this drug often occurs [22]. The link between nutritional conditions, obesity and breast cancer is well established, particularly in menopausal women [23]. However, few studies have evaluated the consequences of metabolic manipulations on the efficiency of anti-cancer therapy. In this work, we studied the effect of treatments that induce protein O-GlcNAcylation on the sensitivity to tamoxifen, using the human breast cancer derived, estrogen receptor positive MCF-7 cell line.

Methods

Chemicals and antibodies

Glucosamine (GlcN) was from Sigma-Aldrich, O-(2-acetamido-2-deoxy-D-glucopyranosylidene)-amino-N-phenylcarbamate (PUGNAc) from Toronto Research Chemicals Inc., and LY294002 from Cell Signaling Technology. Anti-Akt, anti-Phospho-Akt and anti-phospho-Erk1/2 antibodies were from Cell Signaling Technology, anti-ERα (60C) from Millipore, anti-O-GlcNAc (CTD 110.6) from Covance, anti-GAPDH from Life Technologies, anti-β-actin from Sigma, anti-Erk2 (sc 154) and HRP-conjugated donkey anti-rabbit (sc 2305) from Santa Cruz, and HRP-conjugated goat anti-mouse from Jackson ImmunoResearch laboratories.

Cell culture and transfection

MCF-7 cells were maintained in DMEM supplemented with 10% fetal bovine serum. Transfection of siRNA and cDNAs were performed with Lipofectamine RNAi Max (Life Technologies) and FuGene 6 (Promega), respectively. The negative control siRNA was from Eurogentec (Seraing, Belgium).

Uptiblue assay

Cells were plated in clear 96-well-plates at a density of 2000 cells/well. 24 h after plating, cell population density was evaluated 2h30 after adding 10% Uptiblue reagent, by measuring fluorescence (initial fluorescence) at 595 nm using CytoFluor 9600 (Intracel) and then the final fluorescence was measured. The cell population growth in each well was expressed as the ratio of the final fluorescence over the initial one in the same culture well [24].

Apoptosis analysis

After treatment in 6-well-plates, cells were harvested by trypsin digestion, washed in PBS and labelled with both Annexin-V-FITC and propidium iodide using the Annexin-V FLUOS kit (Roche Diagnostics) according to manufacturers’ instructions. Cells were analyzed by flow cytometry with the FC 500 cytometer (Beckman Coulter).

BRET experiments

Luc-Akt-PH and YFP-Mem cDNAs used for the study of PIP3 production have been previously described [25]. MCF-7 cells were transfected with 0.7 µg Luc-Akt-PH and 0.3 µg pYFP-Mem cDNAs per 10.3 mm dish and transferred to a 96 well plate 24 h before BRET experiments. BRET experiments were performed as described previously [26,27]. Results were expressed in miliBRET units as previously described [28,29].

Luciferase assay

The ESR1-Luc reporter gene (firefly luciferase coding sequence under the control of the P1 promoter of ESR1 gene [30], kindly provided by Dr. M. LE ROMANCER-CHERIFI) was used. Cells were seeded in 12-well-plates and transfected 24 h later with 1 µg of ESR1-Luc plasmid combined with 2 ng of a Renilla luciferase cDNA to normalize for transfection efficiency. After treatment, cells were lysed and luciferase activities were measured with a Centro LB 910 luminometer (Berthold) using the DUAL Luciferase Assay kit (Promega).

Western-blotting

MCF-7 cells were lysed with buffer containing 50 mM Tris–HCl (pH 8), 137 mM NaCl, 10% (v/v) glycerol, 1% (v/v) NP40, 50 mM NaF, 10 mM di-sodium β-glycerophosphate, 1 mM Na3VO4, 1 mM streptozotocin and protease inhibitors (1µg/ml pepstatin, antipain, leupeptin, aprotinin and AEBSF). Proteins were then analysed by SDS-PAGE followed by western-blotting [31].

RNA extraction, Reverse Transcription and qPCR

After treatment, cells cultured in 6-well-plate were lysed directly in Trizol reagent (Life Technologies) and RNA were isolated and reverse transcribed as previously described [32]. Levels of the cDNA of interest were measured by qPCR using LightCycler FastStart DNA Master SYBR Green 1 kit. To ensure absence of genomic DNA contamination, RNA samples were treated in parallel without Reverse Transcriptase and controlled for absence of amplification by qPCR. The sequences of the primers used in these experiments are:

- ESR1: Forward, GCATTCTACAGGCCAAATTACG, Reverse, GTGTTATGCTCTTG ATAATC; p21: Forward, TGTAATGGCCCTGCTGCTCAG; Reverse, TGTACCTGCGCGTTCCGTC; EGR1: Forward, GCACCCTGCGAGAAGGTCT, Reverse, AGTGTTGTGCTGGGTTACT; Cyclophilin A: Forward, GGTGACTTC ACAGCcCATAATG, Reverse, ACAAGTGACCAGCCCCGTAT. Gene expression was normalized using cyclophilin A mRNA level as a reference.
Statistical analysis

Statistical analyses were performed with Prism software (GraphPad) using either a t test or ANOVA followed by post-test as indicated in figure legends.

Results

O-GlcNAcylating-inducing treatments protect MCF-7 cells from 4OH-Tamoxifen-induced cell death

We used the Uptiblue, which monitors the cellular growth within the same well, to evaluate the effect of different treatments on MCF-7 cells [24]. Cells were treated with PUGNAc (inhibitor of OGA) and glucosamine (bypasses the GFTA rate limiting step) in absence or presence of 4-OH-Tamoxifen. Treatment with PUGNAc and glucosamine (GlcN) markedly increase O-GlcNAcylation of proteins in MCF-7 cells, both in the absence and presence of 4-OH-Tamoxifen (Figure S1).

Figure 2A shows that treatment with PUGNAc and/or GlcN had no significant effect on cell growth. 4-OH-Tamoxifen markedly reduced the growth of the cell population after 24 h of culture. Interestingly, the effect of 4-OH-Tamoxifen was partially reversed by the presence of either PUGNAc or GlcN, and completely reversed when adding both agents together. Similar results were observed after 48 h of culture with the different agents (Figure 2B). These results suggest that treatment with PUGNAc and GlcN protects MCF-7 cells form 4-OH-Tamoxifen-induced cell death.

We then studied more specifically the effects of 24 h treatments on apoptosis using FACS analysis, after labelling the cells with Annexin V-FITC and propidium iodide. In absence of Tamoxifen, PUGNAc and GlcN had no significant effect on cell apoptosis. Tamoxifen induced a 2-fold increase in apoptosis, which was prevented by the presence of PUGNAc + GlcN (Figure 2C).

To confirm the involvement of O-GlcNAc modifications in protection from 4OH-Tamoxifen-induced cell death, we used siRNA to study the effect of inhibiting OGT expression on apoptosis. As shown in Figure 3A, the expression of OGT was inhibited in siOGT-transfected cells compared to control (siNeg-transfected) cells, which in turn resulted in a decrease in the level of O-GlcNAcylated proteins. Figure 3B shows that inhibition of OGT expression increased tamoxifen-induced cell death. Altogether, these results indicate that increased O-GlcNAcylation protects MCF-7 cells from tamoxifen-induced apoptosis, whereas inhibition of OGT sensitizes these cells to the effects of tamoxifen.

O-GlcNAcylating-inducing treatments stimulate the PI-3 kinase/Akt pathway in MCF-7 cells

The PI-3 kinase/Akt pathway is known as a major anti-apoptotic pathway in MCF-7 cells. To determine whether O-GlcNAcylating-inducing treatments may affect this pathway, we used our previously developed BRET-based assay to monitor PI3 production in intact living cells [25]. In this assay, cells are co-transfected with cDNA coding for the PH domain of Akt fused to Renilla Luciferase and YFP targeted to the plasma membrane (Figure 4A). Cells were incubated with PUGNAc, GlcN or both for 6 h prior to BRET assay. Whereas treatment with PUGNAc or GlcN alone had only modest effects on PI3 production, a significant increase was observed when both agents were added together (Figure 4B, C). In agreement with this result, we observed that PUGNAc+GlcN treatment for 6 or 24 h resulted in increased Akt phosphorylation in MCF-7 cells (Figure 4D).

Protection of 4-OH-Tamoxifen-induced cell death by O-GlcNAcylating-inducing treatments is independent of PI-3 kinase/Akt pathway

To determine whether PUGNAc+GlcN protective effects against 4-OH-Tamoxifen-induced cell death were mediated by their stimulatory effect on PI-3 kinase/Akt pathway, we evaluated the effects of these treatments in presence of LY294002, a PI-3 kinase inhibitor. We observed that LY2940002, which markedly inhibited Akt phosphorylation in these conditions (Figure S2), did not impair PUGNAc+GlcN rescue from 4-OH-Tamoxifen-induced cell death (Figure 5). This result strongly suggested that the protective effect of O-GlcNAcylating-inducing treatment is not mediated by the PI-3 kinase pathway.

Independence of the PI-3 kinase pathway was confirmed by evaluating the effect of IGF-1. As previously demonstrated [25], IGF-1 markedly stimulated PI3 production in these cells (Figure 6A, B). Although IGF-1 had a much higher effect on PI3 production than PUGNAc+GlcN (Figure 6B), no significant rescue from 4-OH-Tamoxifen-induced cell death was observed (Figure 6C). In contrast, the protective effect of PUGNAc+GlcN against tamoxifen induced cell death was still observed, and was similar in absence and presence of IGF1.

Therefore, although these experiments reveal a novel and highly interesting effect of O-GlcNAcylating-inducing treatments on the PI-3 kinase/Akt pathway, protection against 4-OH-Tamoxifen-induced cell death by these treatments appears to be independent of this pathway.

ERα expression is inhibited by increased O-GlcNAcylation in MCF-7 cells

Tamoxifen effects on breast cancer are largely mediated by its antagonistic action against the estrogen receptor. A number of evidences indicate that the breast cancer cell sensitivity to tamoxifen depends on the expression level of the estrogen receptor ERα [33,34]. Low expression level of ESR1 gene, which codes for ERα, is an important determinant of tamoxifen resistance in ER-positive breast tumors [35]. We hypothesised that treatment with O-GlcNAcylating-inducing agents may reduce 4-OH-Tamoxifen-induced cell death through inhibition of ERα. Therefore, we evaluated the effect of PUGNAc+GlcN on the expression of ERα in MCF-7 cells by RT-qPCR and western-blotting. As shown in Figure 7, 24 h treatment of MCF-7 cells with PUGNAC+GlcN markedly reduced ERα expression at both the mRNA and protein levels. Time-course experiments (Figure 8) indicated that inhibition of ERα expression could already be detected at the mRNA level 6 h after of treatment with PUGNAC+GlcN (Figure 8A), and was readily detected at the protein level after 12 h of treatment (Figure 8B).
Figure 2. O-GlcNAcylation-inducing treatments protect from tamoxifen-induced cell death. MCF-7 cells were cultured in presence of 1% FBS during 24 h (A) or 48 h (B), in the absence or presence PUGNAc (100 µM), Glucosamine (GlcN, 5 mM) and 4-OH-tamoxifen (10 µM). The cell population growth in each well was evaluated using an Uptiblue-based-assay as the ratio of final fluorescence over the initial one (broken line) in the same well. Each determination corresponds to measurements performed in triplicate wells. Results are the mean±SEM of at least 7 independent experiments. Statistical analysis was performed using ANOVA followed by Dunnet’s post-test. *, P< 0.05; **, P< 0.01 when compared to untreated control; NS, not significant. (C) MCF-7 cells were cultured in presence of 1% FBS during 24 h, in the absence or presence of PUGNAc+GlcN and 4-OH-tamoxifen (10 µM) and then analysed by FACS after Annexin V-FITC/Propidium Iodide staining. Statistical analysis was performed using ANOVA followed by Tukey’s post-test *, P< 0.05; **, P< 0.01. Results correspond to the mean±SEM of at least 4 independent experiments.

Figure 4. O-GlcNAc-inducing treatments stimulate the PI-3 kinase/Akt pathway in MCF-7 cells. (A) Principle of the BRET assay to measure PIP$_3$ production in living cells. Activation of PI-3 kinase induces the phosphorylation of phosphatidyl-inositol 2 phosphate (PIP$_2$) into phosphatidyl-inositol 3 phosphate (PIP$_3$) and subsequent recruitment of Akt to the plasma membrane through its pleckstrin homology (PH) domain. To monitor the production of PIP$_3$ induced by receptor activation, cells are co-transfected with cDNAs coding for the PH domain of Akt fused to luciferase (Luc-Akt-PH) and YFP fused to a membrane localization sequence. (B) 48 h after transfection, cells were pre-incubated for 6 h in presence of PUGNAc, GlcN or both. Cells were incubated for 10 min with coelenterazine, then light acquisition at 480 nm and 530 nm started. A typical experiment is shown. (C) PUGNAc and GlcNAc-induced BRET (BRET above basal at the plateau). Results are the means ± S.E.M. of 4 to 8 independent experiments. Statistical analysis was performed using ANOVA followed by Dunnet’s post-test. **, P< 0.01 when compared to untreated control. (D) Effect of O-GlcNAcylation-inducing treatment on Akt phosphorylation. MCF-7 cells were incubated in the absence or presence of PUGNAc + GlcN for 6h or 24 h and lysed. The phosphorylation of Akt was evaluated by western-blot using anti-phospho-S473-Akt antibody.

doi: 10.1371/journal.pone.0069150.g004
To determine whether O-GlcNAcylation-inducing treatments affect ERα expression through a transcriptional mechanism, we transfected MCF-7 cells with a reporter gene constituting of the firefly luciferase coding sequence under the control of *ESR1* promoter. Twelve hours after transfection, cells were treated with PUGNAc+GlcN for 24h, and then lysed for luciferase activity measurements. As shown in Figure 9A, PUGNAc+GlcN treatment markedly reduced the expression of *ESR1* promoter reporter gene. To further confirm the role of protein O-GlcNAcylation in the regulation of *ESR1* promoter, a luciferase reporter gene assay was performed after over-expression of OGT. Transfection with OGT cDNA increased OGT expression and protein O-GlcNAcylation in MCF-7 cells (Figure S3). Figure 9B shows that the *ESR1*-Luc reporter gene expression was significantly reduced when OGT cDNA was co-transfected with the reporter gene. To further confirm the role of protein O-GlcNAcylation in the regulation of *ESR1* promoter, a luciferase reporter gene assay was performed after over-expression of OGT. Transfection with OGT cDNA increased OGT expression and protein O-GlcNAcylation in MCF-7 cells (Figure S3). Figure 9B shows that the *ESR1*-Luc reporter gene expression was significantly reduced when OGT cDNA was co-transfected with the reporter gene. This inhibitory effect was accentuated by glucosamine, which provides UDP-GlcNAc to OGT. We also evaluated the effect of PUGNAc+GlcN on ERα expression in presence of tamoxifen. The inhibitory effect of PUGNAc+GlcN on *ESR1* promoter activity was still observed when ERα expression was significantly reduced when OGT cDNA was co-transfected with the reporter gene. This inhibitory effect was accentuated by glucosamine, which provides UDP-GlcNAc to OGT. We also evaluated the effect of PUGNAc+GlcN on ERα expression in presence of tamoxifen. The inhibitory effect of PUGNAc+GlcN on *ESR1* promoter activity was still observed when cells were cultured in presence of tamoxifen (Figure S4A). At the mRNA level, tamoxifen alone tended to decrease the expression of ERα. As a consequence, in presence of tamoxifen, although PUGNAc+GlcN further decreased ERα mRNA level, the difference between cells treated or not with PUGNAc+GlcN was not significant. However, it should be noted that whereas the decrease in mRNA level induced by tamoxifen alone was not significant when compared to untreated control cells, this effect became significant in presence of PUGNAc+GlcN, indicating that PUGNAc+GlcN favours inhibition of ERα mRNA expression, even in presence of tamoxifen (Figure S4B). At the protein level, tamoxifen increased ERα, in agreement with previous data showing that tamoxifen increase ERα protein expression through a post-transcriptional mechanism [36], presumably by protecting ERα from proteasomal degradation [37,38]. However, despite tamoxifen-induced increase in ERα protein level, PUGNAc+GlcN treatment was still capable of significantly decreasing ERα protein expression (Figure S4B and D). This suggests that in presence of tamoxifen, under PUGNAc+GlcN conditions, less ERα protein is available to transmit tamoxifen effects compared to the minus PUGNAc+GlcN condition.

To determine whether O-GlcNAcylation-inhibited ERα expression was associated with an inhibition of tamoxifen effect on gene expression, we studied the mRNA expression of genes coding for p21 and Egr1 by RT-qPCR. p21 and Egr1 negatively regulate cell proliferation and were previously shown to be activated by tamoxifen in MCF-7 cells [39,40]. We
Figure 6. IGF-1 treatment does not protect MCF-7 cells from 4OH-tamoxifen-induced cell death. (A) MCF-7 cells were co-transfected with cDNAs coding for the PH domain of Akt fused to luciferase (Luc-Akt-PH) and YFP fused to a membrane localization sequence. 48 h after transfection, cells were pre-incubated for 6 h in the absence or presence of PUGNAc+GlcN. Cells were incubated for 10 min with coelenterazine and then stimulated with 100 nM IGF-1. Light acquisition at 480 nm and 530 nm started immediately after IGF-1 addition. A typical experiment is shown. (B) PUGNAc+GlcNAc and IGF-1-induced BRET (BRET above basal at the plateau). Results are the means ± S.E.M. of at least 5 independent experiments. doi: 10.1371/journal.pone.0069150.g006
observed PUGNAc+GlcN reduced the stimulatory effect of tamoxifen on the expression of these genes (Figure 10).

Altogether, these data suggest that O-GlcNAcylation-inducing treatments inhibited ERα expression, and this
Figure 8. Time-course of inhibition of ERα expression by O-GlcNAcylation-inducing treatments. Cells were cultured in absence or presence of PUGNAc+GlcN for 6, 12, 24 and 36 h. (A) RNA was extracted and the expression of ERα mRNA was evaluated by RT-qPCR. Statistical analysis was performed using unpaired t test. *, P< 0.05; **, P< 0.01; ***, P< 0.001. doi: 10.1371/journal.pone.0069150.g010
inhibition was associated with a reduction of tamoxifen effect on key genes involved in regulation of cell proliferation.

Discussion

O-GlcNAcylation has been implicated as an important determinant in cancer cell growth and migration [16–21]. However, its role in the sensitivity to anti-cancer therapy was not investigated in these studies. In the present work, we demonstrate that increasing O-GlcNAcylation results in important protective effects against tamoxifen-induced cell death in the MCF-7 cell line.

In MCF-7 cells, increased activity of the PI-3 kinase/Akt pathway has been previously shown to participate in resistance to various chemotherapeutic agents, including tamoxifen [41]. To evaluate the potential involvement of this pathway in the protective effects of O-GlcNAc-inducing treatments, we used our previously developed BRET-based assay to assess PIP$_3$ level in living cells. We observed that PUGNAc+GlcN treatment significantly increased PIP$_3$ production in MCF-7 cells and was associated with an increase in Akt phosphorylation. Interestingly, recent work also suggested a link between PI-3 kinase activity and OGT expression level in cancer cells [42]. The mechanism by which O-GlcNAc increases PI-3K/Akt pathway activity in MCF-7 cells remains elusive. Whereas O-GlcNAcylation of the p85 subunit [43] of PI-3K has been previously described, its consequences on its activity have not been studied. Moreover, whereas O-GlcNAcylation of Akt has been largely described [5,9,44,45], this modification is rather associated with a decrease in its phosphorylation. PIP$_2$ level at the plasma membrane depends on the balance between PIP$_2$ phosphorylation by PI-3 kinase activity and PIP$_3$ dephosphorylation by the lipid-phosphatase PTEN. Clearly, the effect of O-GlcNAc treatment on PI-3 kinase and PTEN expression and/or activity in MCF-7 cells deserves further investigations.

Whatever the mechanism involved in O-GlcNAc-induced increase in PI-3-kinase/Akt pathway in these cells, it does not appear to play a significant role in the protective effect of O-GlcNAc against tamoxifen-induced cell death. Indeed, pharmacological inhibition of the PI-3 kinase/Akt pathway using LY294002 did not impair the protective effects of PUGNAc+GlcN treatments on 4-OH-tamoxifen induced cell death. Moreover, using IGF1, we demonstrated that activation of PI-3 kinase is not sufficient to rescue MCF-7 cells from tamoxifen effects, whereas PUGNAc+GlcN treatment was still efficient under these conditions. This prompted us to investigate whether O-GlcNAcylaton, rather than acting through a general anti-apoptotic signalling pathway, may affect a protein more specifically involved in tamoxifen action.

Tamoxifen exerts its effects on estrogen-receptor positive cells by binding to ERα. ERα expression is both necessary and sufficient to predict the responsiveness to anti-estrogen in a high proportion of breast tumors, and low expression level is generally associated with a poor prognosis [33–35,46,47].

We observed that O-GlcNAcylation-inducing treatment results in inhibition of ERα expression, suggesting a potential mechanism for decreased tamoxifen effect. Inhibition of ERα mRNA expression could be detected after only 6 h of treatment, and luciferase reporter gene assay indicated that PUGNAc+GlcN treatments inhibit the activity of the ESR1 promoter reporter gene. This suggests that the inhibition of ERα expression occurred at least in part through a transcriptional repression mechanism. This inhibition appeared to be independent of the effect of O-GlcNAc on PI-3 kinase/Akt pathway, because treatment of MCF-7 cells with LY294002 did not impair inhibition of ERα expression by PUGNAc+GlcN treatment (data not shown).

Positive and negative regulation of gene expression by post-translational modification of transcription factors has been largely documented [8,48,49]. Interestingly, Sp1, one of the first transcription factors identified to be modified by O-GlcNAcylation [50], is known to bind to and positively regulate the ESR1 promoter activity [51]. Indeed, Sp1 appears to participate in a transcription complex (comprised of USF1 and ERα itself) that regulates the expression of ESR1. O-GlcNAcylation of Sp1 has been largely associated with decreased transcriptional activity on various promoters, generally through dissociation of its interaction with transcription factors or co-activators [52–58]. Therefore, it would be of interest to determine whether the effect of PUGNAc+GlcN in MCF-7 cells is associated with dissociation of this complex.

Expression of the ERα, a good prognostic factor in breast cancer, is associated with higher levels of p21 proteins. Tamoxifen is known to modulate the expression of genes involved in cell proliferation and cell death. Increased expression of the cell cycle regulator p21$^{\text{WAF1/CIP1}}$ is believed to play a role in cell cycle arrest upon treatment with tamoxifen and other anti-estrogen drugs [39,59]. Moreover, down-regulation of p21$^{\text{WAF1/CIP1}}$ using antisense RNA abrogates anti-estrogen-mediated cell cycle arrest in MCF-7 cells [39]. Similarly, Egr1 is deleted in ER-negative human breast carcinoma, which is suggested to contribute to the poor prognosis of ER-negative versus ER-positive breast carcinomas [60]. Decreased Egr1 expression in human, mouse and rat mammary cells and tissues correlated with tumor formation, and tamoxifen treatment was shown to restore its expression in rat mammary tumors [40]. Moreover, in the ER-positive breast cancer cells MDA-MB-361, tamoxifen-induced increase in Egr1 expression resulted in activation p21$^{\text{WAF1/CIP1}}$ promoter and increased transcription of p21$^{\text{WAF1/CIP1}}$ gene, providing a link between Egr1 transcriptional activity, p21 expression and tamoxifen-induced cell cycle arrest [61]. Our results indicated that O-GlcNAcylation-inducing treatment reduced the stimulatory effect of tamoxifen on Egr1 and p21 expression, providing a potential mechanism for the protective effects of O-GlcNAc on tamoxifen-induced inhibition of cell growth. However, the effect tamoxifen on Egr1 and p21 gene expression is only partially inhibited by O-GlcNAc-inducing treatments. This may in part reflect the fact that O-GlcNAc-induced inhibition of ERα expression is only partial (Figures 7 and 8), and the remaining receptors could be responsible for the residual effect of tamoxifen.

In summary, we have observed that increased O-GlcNAcylation in MCF-7 cells have inhibitory effects on
O-GlcNAc Inhibits Tamoxifen Effects in MCF-7 Cells

Tamoxifen induced cell death. Although O-GlcNAc-inducing treatments stimulate the PI-3 kinase/Akt pathway through an unknown mechanism, protection from tamoxifen-induced cell death appear to be independent of this pathway. Moreover, we observed that increased O-GlcNAcylation reduces the expression of ERα, one of the main determinants of tamoxifen sensitivity. However, several laboratories have shown that tamoxifen can have ERα-independent anti-proliferative and pro-apoptotic effects [62–64]. In the present study, it cannot be ruled out that O-GlcNAcylation may also protect MCF-7 cells from ERα-independent effects of tamoxifen. Therefore, additional work will be required to determine to what extent reduction in ERα expression is responsible for reduced tamoxifen effect upon O-GlcNAcylation-inducing treatment. Overall, although no firm conclusion can be drawn concerning the mechanism(s) by which O-GlcNAcylation protects MCF-7 cells from tamoxifen effects, our results suggest that targeting the O-GlcNAc pathway might be an interesting therapeutic approach for sensitisation of anti-estrogen resistant breast tumors.

Supporting Information

Figure S1. Effect of PUGNac and Glucosamine on O-GlcNAc level in MCF-7 cells treated or not with 4-OH-tamoxifen. MCF-7 cells cultured in absence (Ct) or presence of PUGNac (P), glucosamine (G) or PUGNac+glucosamine (PG), were treated or not with 4-OH-tamoxifen (10 µM). After 24 h of treatment, cells were lysed and protein O-GlcNAcylation level was evaluated by western-blotting. GAPDH expression level was used as a loading control. (TIF)

Figure S2. Effect of LY294002 on Akt phosphorylation in MCF-7 cells. MCF-7 cells treated with 10 or 20 µM LY294002 (LY) or vehicle (DMSO) were cultured during 24 h in absence or presence PUGNac+Glcn and/or tamoxifen. Cells were lysed and Akt phosphorylation level was evaluated by western-blotting using anti-phospho-S473-Akt antibody. As a control for the mechanism(s) by which O-GlcNAcylation protects MCF-7 cells from tamoxifen effects, our results suggest that targeting the O-GlcNAc pathway might be an interesting therapeutic approach for sensitisation of anti-estrogen resistant breast tumors.

Acknowledgements

We are very grateful to Dr. M. LE ROMANCER-CHERIFI (Centre de Recherche en Cancérologie de Lyon, Centre Léon Bérard) for kindly providing the ESR1-reporter gene. We are very grateful to Dr. Sherri S. Smith for language corrections.
