ABSTRACT

Gastric cancer (GC) remains one of the most important malignant diseases with significant geographical, ethnic, and socioeconomic differences in distribution. Sentinel lymph node (SLN) mapping is an accepted way to assess lymphatic spread in several solid tumors; however, the complexity of gastric lymphatic drainage may discourage use of this procedure, and the estimated accuracy rate is, in general, reasonably good. This study aimed at reviewing the current status of SLN mapping and navigation surgery in GC. SLN mapping should be limited to tumors clinically T1 and less than 4 cm in diameter. Combination SLN mapping with radioactive colloid and blue dye is used as the standard. Despite its notable limitations, SLN mapping and SLN navigation surgery present a novelty individualizing the extent of lymphadenectomy.

Keywords: Lymph node mapping, gastric cancer, surgery

INTRODUCTION

Gastric cancer (GC) remains one of the most important malignant diseases with significant geographical, ethnic, and socioeconomic differences in distribution (1). Gastric cancer is the second leading cause of death from malignant diseases worldwide, with especially high mortality rates in East, South, and Central Asia; Central and Eastern Europe; and South America. Gastric cancers are most frequently discovered in advanced stages, except in East Asia, where screening programs have been established. The prognosis of advanced GC remains poor, and curative surgery is regarded as the only option for cure. Early detection of resectable GC is extremely important for good patient outcomes; therefore, technologically sophisticated screening programs are needed. In the near future, however, improving the prognosis of advanced GC is necessary, which includes multimodality treatment using chemotherapy, radiotherapy, and surgery (2).

Sentinel lymph node (SLN) mapping is an accepted way to assess lymphatic spread in several solid tumors (i.e. breast cancer, vulvar cancer and melanoma). In an ideal world, SLN mapping should be as good as systematic lymphadenectomy in the identification of patients with lymph node dissemination, while reducing the morbidity associated with an extensive surgical procedure. In breast cancer and melanoma surgery, SLN biopsy has proven to be a valuable tool in lymph node mapping with a sensitivity of more than 95%. When SLN biopsy is negative, lymphadenectomy can safely be omitted. Hence, SLN biopsy is now routinely practiced in these cancer types (3).

Although the complexity of gastric lymphatic drainage may discourage the use of this procedure, the estimated accuracy rate is, in general, reasonably good (4).
primary location via the lymphatic system (4). Nodal metastases are observed in 3%-5% of the gastric carcinomas which are limited to the mucosa, 11%-25% of which extend to the submucosa, 50% of which reach the muscularis propria (T2), and 83% of which extend to the serosa (T3) (4). After curative radical resection, local recurrence is represented in 87.5% of cases by nodal metastases to local or regional lymph node stations (4).

The Japanese Classification of Gastric Carcinoma (Japanese Gastric Cancer Association, JGCA, 1998) (5) has defined 16 different lymph node stations (n) which drain the stomach (Figure 1). These are subdivided into three levels according to their distance from the tumor, thus entailing three types of lymph node dissection (D) that can be associated to total or partial gastrectomy: D1, in which perigastric lymph nodes from n1 to n6 are removed (N1 level); D2, in which perigastric lymph nodes are removed as well as those located along the main arterial vessels from n7 to n12 (N2 level); D3, in which stations n13 to n16 are removed, as well as those mentioned before (N3 level). During the 1960s, the Japanese authors first introduced D2 lymphadenectomy in patients with potentially curable advanced gastric carcinoma. Short- (6) and long-term (7) results of a comparative randomized controlled trial (RCT) between D1 and D3 (the D3 definition reported in did not include para-aortic lymph nodes) conducted on 221 patients who received curative surgery in a single institution were reported in 2004 and 2006. The authors concluded that D3 dissection improves survival rates, and suggested that it should be performed in specialized centers in order to limit the chance of postoperative complications. A RCT conducted by the East Asia Surgical Oncology Group in 2008 (8) compared the data of 135 patients treated with D2 gastrectomy, with 134 patients receiving D4 gastrectomy (in D4 dissection inter-, pre-, and latero-aortic lymph nodes of abdominal aorta as far as bifurcation are removed). The authors stated that D4 dissection is not the best treatment option for patients with gastric carcinoma, whereas D2 dissection is recommended if performed by experienced surgeons. The Dutch Gastric Cancer Group Trial (9), published in 2004, updated data on the survival of 711 patients previously enrolled in published RCTs. The authors concluded that D2 lymph node dissection can be recommended only if operative morbidity and mortality can be reduced. A further update of these data was published in 2010 (10), with a median follow-up of 15.2 years. The overall 15-year survival was 21% after D1 resection and 29% after D2 resection (P= 0.34). Gastric cancer-related mortality rates resulted significantly higher in D1 than in D2 (41% vs 37%; P= 0.01). The incidence of local recurrence (D1= 22% vs D2= 12%) and distant recurrence (D1= 19% vs D2= 13%) were different, albeit not significantly. Patients who received splenectomy and pancreatectomy had significantly lower overall survival rates in both D2 and D1 groups. On the other hand, patients who received D2 resection without pancreatico-splenectomy had a significantly higher overall 15-year survival compared to patients receiving D1 resection (35% vs 22%, P= 0.006). The authors concluded that D2 resection should be considered the standard procedure to treat resectable gastric carcinoma. The Italian Gastric Cancer Study Group (11) published a multicentric RCT on 267 patients in 2010, comparing the short-term results of D1 and D2 gastrectomy for curable GC. Pancreatocopancreatectomy was not considered a routine part of D2 gastrectomy, and the spleen and pancreas were removed only when indicated by the surgeon. The study did not show significant differences in terms of operative mortality, morbidity and duration of postoperative

hospital stay. The authors concluded that D2 gastrectomy is a safe option to treat gastric carcinoma of Western patients as well, if it is performed in specialized centers (11).

In conclusion, in Western countries the prognostic value of D2 lymphadenectomy is still controversial, while in Eastern countries it is considered a standard procedure, likely to be further extended. Japanese authors do not even conduct RCT comparing D1 and D2 lymphadenectomies on the grounds that they consider D1 dissection unethical. Data indicate that D2 dissection is an adequate and potentially beneficial staging and treatment approach if operative mortality is avoided. Dissections extended to para-aortic lymph nodes do not show significant advantages in terms of survival. Splenectomy and distal pancreatectomy increase operative morbidity and mortality. D2 dissection is considered a difficult procedure and should be performed by experienced surgeons in specialized centers. Authors suggest that a surgeon should perform at least 200 gastrectomies under the supervision of an experienced surgeon before he can perform D2 lymph node dissections with acceptable morbidity and mortality rates (4). In Western countries, due to the lower incidence of gastric carcinoma, a surgeon is very unlikely to achieve such an experience (4).

**Rationale of SLN Mapping and Biopsy**

In GC, lymph node status is one of the most important prognostic factors. The extent of gastrectomy and lymphadenectomy is largely based on the likelihood of lymph node metastases to first- (N1) and second-tier (N2) lymph node stations. The applicability of SLN biopsy in GC has been studied in recent years in an effort to accurately predict metastasis to non-regional lymph nodes. The ultimate goal is to identify patients who truly need lymphadenectomy and to identify patients in whom lymphadenectomy can be omitted. Obviously, patients with suspicious or proven lymph node metastases are not eligible for SLN biopsy, and a routine D2 lymphadenectomy is deployed. Additionally, in patients with advanced tumors (T3 and more), SLN biopsy does not seem appropriate. These patients already have a high probability of having first- or second-tier lymph node metastases. Moreover, in advanced tumors, original lymphatic drainage routes might be obstructed or altered, resulting a lower accuracy of the SLN biopsy (1).

Surgical procedures for gastric cancer have been changing, for instance endoscopic mucosal or sub-mucosal resection, minimally invasive surgery and individualized management have become popular. For lymph node dissection, D2 lymph node dissection has been accepted standard procedure (5, 12). Since the early stage of GC has increased and SLN status is one of the most important prognostic factors, the extent of lymph node dissection is crucial during minimal invasive surgery. For this reason, the method to evaluate lymph node metastasis becomes more important. Behind the lymph node navigation method, complicated lymphatic drainage of the gastrointestinal system, possibility of micro and/or skip metastases are other issues in SLN evaluation.

**Tracers**

Selection of optimal radioactive tracers for SLN mapping is an important issue. Although most studies focus on a single tracer, using a dual-tracer method (dye plus radioactive) would be more accurate in routine practice. Moreover, several controversies have remained such as the injection way or timing and volume of the tracer. Kitagawa et al. have shared their experience and reported that tin colloid particles migrates to SLN within 2 hour and remains about 20 minutes. They have also recommended endoscopic or laparoscopic injection (13) and (14) suggested that technetium-99m tin colloid is recommended as an optimal tracer for SLN mapping for gastric cancer.

Peparini (15) has suggested that advances in imaging technologies could allow a more accurate preoperative detection of SLN than the current dye- or radio-guided methods. Moreover, new dye-guided intraoperative technologies might revolutionize the SLN mapping procedure in gastrointestinal cancers. Indocyanine green (ICG) infrared or fluorescence imaging may identify a higher number of SLN than radio-guided methods because the particle size of the dyes is smaller than that of radioactive colloids. In GC, ICG infrared imaging is a useful tool in the laparoscopic detection of SLN. ICG fluorescence imaging is feasible even by preoperative ICG injection at, for instance, 1 or 3 d before surgery; it is also feasible in laparoscopy-assisted gastrectomy via a small laparotomy (15).

**Injection Route of Tracers**

Submucosal injection of the tracer using an endoscope is a standard procedure in the trial conducted by the Japan Society of Sentinel Node Navigation Surgery (16).

Nevertheless, several researchers have reported that there is no difference in the detection rate, mean number of SLN, and sensitivity of the SLN biopsies between submucosal and subserosal injection (17,18).

**Operative Technique to Retrieve SLN**

Two techniques to retrieve SLN have been reported: the pick-up method and lymphatic basin dissection (LBD). The pick-up method is a very popular method for breast cancer and melanoma, but it is not applicable to GC (19). In the pick-up method, hot node or nodes are dissected, but in LBD, not only hot node also cold nodes are dissected. Kelder et al. have demonstrated that intra-operative accuracy for detecting SLN metastasis is 50% with node picking versus 92.3% with LBD (20).

**Clinical Results**

Radioguided SLN mapping is an accurate diagnostic procedure for detecting lymph node metastasis in patients with clinical T1-2N0 GC. Since the main purpose of introducing this technology
Lymph node mapping in gastric cancer surgery

into GC surgery is to extend the indication of minimally invasive surgery for pathologically node negative cases, there is no advantage to include advanced cases for which modified less-invasive surgical approaches are not applicable. The size of the primary lesion is also an important factor to consider regarding this technique. It is difficult to cover a whole lymphatic drainage route from a larger tumor exceeding 4 cm (21).

Nakajo et al. (22) have suggested that T1N0 patients are possible candidates for SLN scintigraphy. They have reported high micrometastases rate even in patients that do not have suspected lymph nodes during preoperative evaluation. Similarly, Kitagawa et al. (13) have found the detection rate as 95% and the accuracy as 98%. Saikawa et al. (23) have evaluated the accuracy of SLN scintigraphy in 35 T1No GC patients. They have reported a 94.3% detection rate and 97% accuracy. The only patient with false negative result had advanced GC with invasion into the proper muscular layer and vascular vessel invasion, causing destruction of normal lymphatic flow. At another view of aspect, Nakahara et al. (24) have reported the relation of body mass index (BMI) and success of preoperative lymphoscintigraphy, and they have found a significant difference between BMIs of successful and unsuccessful groups. Kitagawa et al. (25) have calculated the detection rate of sentinel node with dual tracer method (Tc-99m Tin Colloid and blue dye) as 97.5% in their large cT1 and cT2 gastric carcinoma group. They have reported 3 out of 4 false negative sentinel lymph node biopsies were pT2 tumors. They suggested that sentinel lymph node biopsy would be more successful in T1 tumors because false negative rate is higher in T2 tumors. Table 1 summarizes the clinical success of the studies.

Meta analyses results suggest that further studies are needed to confirm the best procedure and standard criteria for the clinical application of SLN mapping in GC (26,27).

CONCLUSION

Gastric cancer is now one of the most suitable targets of an individualized less-invasive surgery based on the SLN concept although there are several unresolved issues. In our opinion, SLN mapping and SLN navigation surgery present a novelty individualizing the extent of lymphadenectomy for GC.
