EXACT ENUMERATION OF 1342-AVOIDING PERMUTATIONS
A CLOSE LINK WITH LABELED TREES AND PLANAR MAPS

MIKLÓS BÓNA

Abstract. Solving the first nonmonotonic, longer-than-three instance of a classic enumeration problem, we obtain the generating function $H(x)$ of all 1342-avoiding permutations of length $n$ as well as an exact formula for their number $S_n(1342)$. While achieving this, we bijectively prove that the number of indecomposable 1342-avoiding permutations of length $n$ equals that of labeled plane trees of a certain type on $n$ vertices recently enumerated by Cori, Jacquard and Schaeffer, which is in turn known to be equal to the number of rooted bicubic maps enumerated by Tutte in 1963. Moreover, $H(x)$ turns out to be algebraic, proving the first nonmonotonic, longer-than-three instance of a conjecture of Zeilberger and Noonan. We also prove that $\sqrt[n]{S_n(1342)}$ converges to 8, so in particular, $\lim_{n \to \infty} (S_n(1342)/S_n(1234)) = 0$.

1. Introduction

1.1. Our main results. In this paper we are going to prove an exact formula for the number $S_n(1342)$ of 1342-avoiding permutations of length $n$ showing that

\[ S_n(1342) = \frac{(7n^2 - 3n - 2)}{2} \cdot (-1)^{n-1} + 3 \sum_{i=2}^{n} 2^{i+1} \cdot \frac{(2i - 4)!}{i!(i-2)!} \cdot \binom{n - i + 2}{2} \cdot (-1)^{n-i}, \]

by first proving that the ordinary generating function $H(x)$ for these numbers $S_n(1342)$ has the following simple form:

\[ H(x) = \frac{32x}{-8x^2 + 12x + 1 - (1 - 8x)^{3/2}}. \]

This is the first result we know of which provides an exact formula for the number $S_n(q)$ of permutations of length $n$ avoiding a given pattern $q$ that is longer than three and is not 1234. Results concerning the case of length three can be traced back to two centuries; [4] already makes references to earlier work. The formula for $q = 1234$ is given in [8]. Until recently it has not even been known that $S_n(1342) < c^n$ for some constant $c$. In [1] this upper bound with $c = 9$ was proved. This paper’s result pushes down this $c$ to 8, and proves that it is optimal. (Definitions and more background information can be found in the next subsection).

In our proof, we are going to present a new link between the enumeration of permutations avoiding the pattern 1342 and the that of $\beta(0,1)$-trees, a class of

---

labeled trees recently introduced in [3]. We will show that the number $I_n(1342)$ of indecomposable 1342-avoiding permutations of length $n$ is equal to the number of $\beta(0,1)$-trees on $n$ nodes. The set $D_n^{\beta(0,1)}$ of $\beta(0,1)$-trees on $n$ nodes is known [2] to be equinumerous to the set of rooted bicubic maps on $2(n + 1)$ vertices, and an exact formula for the number $t_n$ of these is provided in [10]. Therefore, $I_n(1342) = |D_n^{\beta(0,1)}| = t_n = 3 \cdot 2^{n-1} \frac{(2n)!}{(n+2)!}$. So combinatorially, the number of all $n$-permutations avoiding 1342 will be shown to be equal to that of plane forests on $n$ vertices in which each component is a $\beta(0,1)$-tree. To our best knowledge, this is the first time when permutations avoiding a given pattern are shown to have such a close connection with some planar maps, though recently 2-stack-sortable permutations have been shown to be equinumerous to nonseparable planar maps [3] [4].

Examining the generating function $H(x)$ we will prove and disprove several conjectures for the pattern 1342. $H(x)$ turns out to be algebraic, proving a conjecture of Zeilberger and Noonan [19] for the first time for a nonmonotonic pattern which is longer than three. We will see that $\sqrt{n} S_n(1342) \rightarrow 8$, which disproves a conjecture of Stanley and implies the surprising fact that $\lim_{n \rightarrow \infty} \left( S_n(1342) / S_n(1234) \right) = 0$.

1.2. Definitions and Background. In what follows permutations of length $n$ will be called $n$-permutations. A permutation is called indecomposable if it cannot be cut in two parts so that everything before the cut is larger than everything after the cut. Let $q = (q_1, q_2, \ldots, q_k)$ be a $k$-permutation and let $p = (p_1, p_2, \ldots, p_n)$ be an $n$-permutation. We say that $p$ avoids $q$ if $1 \leq i_{q_1} < i_{q_2} < \ldots < i_{q_k} \leq n$ such that $p(i_1) < p(i_2) < \ldots < p(i_k)$. For example, $p$ avoids 132 if it cannot be written as $\ldots, a, \ldots, b, \ldots, c, \ldots$ so that $a < c < b$. For another example, a permutation is 1234-avoiding if it doesn’t contain an increasing subsequence of length 4.

It is a natural and easy-looking question to ask how many $n$-permutations avoid a given pattern $q$. Throughout this paper, this number will be denoted by $S_n(q)$.

However, this problem turns out to be very hard. Exact answers have only been known for the easy case of patterns of length 3 [11]. In that case $S_n(q) = C_n$, the $n$-th Catalan number, for any such pattern $q$. If $q$ is longer than three, then the most exact result is due to Regev [10] and says that for all $n$, $S_n(1234 \cdots k)$ asymptotically equals $C_{n(k-1)^2n}$, where $c$ is a constant given by a multiple integral. The major problem of this area is to prove the conjecture of Wilf and Stanley [18] from 1990, stating that for each pattern $q$ there is an absolute constant $\lambda$ so that $S_n(q) < \lambda^n$ holds. This has been proven for the case of length 4 and some longer patterns in [4]. The general case is, however, still open.

Stanley [13] conjectured that $\sqrt[n]{S_n(q)}$ converges to $(k-1)^2$ where $k$ is the length of $q$. The results of this paper will indicate the disproof of this conjecture for the pattern 1342, in fact, our formula for $S_n(1342)$ clearly implies that $\sqrt[n]{S_n(1342)} \rightarrow 8$. This shows in particular that $(S_n(1342)/S_n(1234)) \rightarrow 0$ when $n \rightarrow \infty$ as $\sqrt[n]{S_n(1234)} \rightarrow 9$.
by the above results of Regev [10] and Gessel [8] for monotonic patterns. We would like to point out the surprising nature of this discovery: while $S_n(q) = \binom{2n}{n}/(n+1)$ for any patterns $q$ of length three, for the case of length four there are sequences $S_n(q)$ that are not only different from each other, but their quotient also converges to 0.

We note that while there are 24 permutation patterns of length 4, for many of them the sequences $S_n(q)$ are identical. In fact, there are only three different classes of patterns from this point of view, $[17]$, $[12]$, $1342$, $1234$ and $1324$ are representants of them.

Recently, attention has been paid to the problem of counting the number of permutations of length $n$ containing a given number $r$ (as opposed to 0) of subsequences of a certain type $q$.

The major problem of this field is to describe this function for any given $r$, not just for $r = 0$. In [19] Noonan and Zeilberger conjectured that for any given subsequence $q$ and for any given $r$, the number of $n$-permutations containing exactly $r$ subsequences of type $q$ is a $P$-recursive function of $n$. Present author has proved this conjecture for any $r$ when $q = 132$. Beyond the case of length 3, however, there have been no nonmonotic instances solved prior to this paper, not even for the case of $r = 0$. Even in the case of length 3, exact formulae have only been given for $r = 1$ ([9] for $q = 123$ and [3] for 132). The case of monotonic patterns and $r = 0$ has been handled in [20]. Figure 1 shows the present state of research on permutations avoiding given patterns of length 4, including the contributions of this paper.

| Pattern | Known  | Formula          | P-recursive |
|---------|--------|------------------|-------------|
| 1234    | known | [11]             | known [20]  |
| 1342    | known | this paper       | known this paper |
| 1324    | known | open             | open        |

Figure 1
In the following two paragraphs we give a very brief summary of \( P \)-recursive and algebraic generating functions. The reader familiar with them can skip these paragraphs.

A function \( f : \mathbb{N} \to \mathbb{C} \) is called \( P \)-recursive if there exist polynomials \( P_0, P_1, \ldots, P_k \in \mathbb{Q}[n] \), with \( P_k \neq 0 \) so that
\[
P_k(n)f(n) + P_{k-1}(n)f(n+k-1) + \cdots + P_0(n)f(n) = 0 \tag{1}
\]
for all natural numbers \( n \). Here \( P \)-recursive stands for “polynomially recursive”.

The continuous analogue of this notion is \( d \)-finiteness, which stands for “differentiably finite”. Let \( u(x) \in \mathbb{C}[[x]] \) be a power series. If there exist polynomials \( p_0(x), p_1(x), \ldots p_d(x) \) so that \( p_d \neq 0 \) and
\[
p_d(x)u^{(d)}(x) + p_{d-1}(x)u^{(d-1)}(x) + \cdots + p_1(x)u'(x) + p_0(x)u(x) = 0, \tag{2}
\]
then we say that \( u \) is \( d \)-finite. (Here \( u^{(j)} = \frac{d^j u}{dx^j} \)). It is well-known \([13]\) that a function \( f(n) \) is \( P \)-recursive if and only if its ordinary generating function \( u(x) = F(x) = \sum_{n \geq 0} f(n)x^n \) is \( d \)-finite.

Another, smaller class of formal power series is that of algebraic series. We say that the series \( v(x) \in \mathbb{C}[[x]] \) is algebraic if there exist polynomials \( p_0(n), p_1(n), \ldots p_{d-1}(n) \) so that \( p_{d-1} \neq 0 \) and
\[
v^d(x) + p_{d-1}(x)v^{d-1}(x) + \cdots + p_1(x)v(x) + p_0(x) = 0. \tag{3}
\]
Any algebraic power series is necessarily \( d \)-finite.

As we have mentioned, we are going to prove our results by showing connections between these permutations and rooted bicubic maps. These are planar maps with 2-colorable vertices which in addition all have degree three and a distinguished “root” edge and face. We will make good use of a class of labeled rooted trees called \( \beta(0,1) \)-trees introduced in \([5]\). Their definition is at the beginning of the next section.

2. The correspondence between trees and permutations

**Definition 1.** \([5]\) A rooted plane tree with nonnegative integer labels \( l(v) \) on each of its vertices \( v \) is called a \( \beta(0,1) \)-tree if it satisfies the following conditions:

- if \( v \) is a leaf, then \( l(v) = 0 \),
- if \( v \) is the root and \( v_1, v_2, \ldots, v_k \) are its children, then \( l(v) = \sum_{i=1}^{k} l(v_k) \),
- if \( v \) is an internal node and \( v_1, v_2, \ldots, v_k \) are its children, then \( l(v) \leq 1 + \sum_{i=1}^{k} l(v_k) \).

A branch of a rooted tree is a tree whose top is one of the root’s children. Some rooted trees may have only one branch, which doesn’t necessarily mean they consist of a single path.
We start by treating two special types of $\beta(0, 1)$-trees on $n$ vertices. These cases are fairly simple—they will correspond to 231-avoiding (resp. 132-avoiding) permutations, but they will be our tools in dealing with the general case.

First we set up a bijection $f$ from the set of all 1342-avoiding $n$-permutations starting with the entry 1 and the set of $\beta(0, 1)$-trees on $n$ vertices consisting of one single path. In other words, the former is the set of 231-avoiding permutations of the set $\{2, 3, 4, \ldots, n\}$.

So let $p = (p_1p_2\cdots p_n)$ be an 1342-avoiding $n$-permutation so that $p_1 = 1$. Take an unlabeled tree on $n$ nodes consisting of a single path and give the label $l(i)$ to its $i$th node $(1 \leq i \leq n - 1)$ by the following rule:

$$l(i) = \# \{j \leq i \text{ so that } p_j > p_s \text{ for at least one } s > i \}.$$

Finally, let $l(n) = l(n-1)$. In words, $l(i)$ is the number of entries on the left of $p_i$ (inclusive) which are larger than at least one entry on the right of $p_i$. We note that this way we could define $f$ on the set of all $n$-permutations starting with the entry 1, but in that case, as we will see, $f$ would not be a bijection. (For example, the images of 1342 and 1432 would be identical).

**Example 1.** If $p = 14325$, then the labels of the nodes of $f(p)$ are, from the leaf to the root, 0, 1, 2, 0, 0.

**Lemma 1.** $f$ is a bijection from the set of $D_n^{\beta(0, 1)}$ of all $\beta(0, 1)$-trees on $n$ vertices consisting of one single path to the set of 1342-avoiding $n$-permutations starting with the entry 1.

**Proof:** It is easy to see that $f$ indeed maps into the set of $\beta(0, 1)$-trees: $l(i + 1) \leq l(i) + 1$ for all $i$ because there can be at most one entry counted by $l(i + 1)$ and not counted by $l(i)$, namely the entry $p_{i+1}$. All labels are certainly nonnegative and $l(1) = 0$.

To prove that $f$ is a bijection, it suffices to show that it has an inverse, that is, for any $\beta(0, 1)$-tree $T$ consisting of a single path, we can find the only permutation $p$ such that $f(p) = T$. We claim that given $T$, we can recover the entry $n$ of the preimage $p$. First note that $p$ was 1342-avoiding and started by 1, so any entry on the left of $n$ must have been smaller than any entry on the right of $n$. In particular, the node preceding $n$ must have label 0. Moreover, $n$ is the leftmost entry $p_i$ of $p$ so that $p_j > 0$ for all $j \geq i$ if there is such an entry at all, and $n = p_n$ if there is none. That is, $n$ corresponds to the node which starts the uninterrupted sequence of strictly positive labels which ends in the last node, if there is such a sequence, and corresponds to the last node otherwise. To see this, note that $n$ is the largest of all entries, so in particular it is always larger than at least one entry in any nonempty set of entries.

Once we located where $n$ was in $p$, we can simply delete the node corresponding to it from $T$ and decrement all labels after it by 1. (If this means deleting the last
node, we just change $l(n-1)l(n-2)$ to satisfy the root-condition). We can indeed do this because the node preceding $n$ had label 0, and the node after $n$ had a positive label, by our algorithm to locate $n$. Then we can proceed recursively, by finding the position of the entries $n-1, n-2, \ldots, 1$ in $p$. This clearly defines the inverse of $f$, so we have proved that $f$ is a bijection.

\textbf{Lemma 2.} The number $\beta(0,1)$-trees with all labels equal to zero is $C_{n-1}$.

\textbf{Proof:} These $\beta(0,1)$-trees are in fact unlabeled plane trees. We prove that they are in one-to-one correspondence with the 132-avoiding permutations whose last entry is $n$. Suppose we already know this for all positive integers $k < n$. Let $T$ be a $\beta(0,1)$-tree on $n$ vertices with all labels equal to 0 and root $r$. Let $r$ have $t$ children, which are, from left-to-right, at the top of such unlabeled trees $T_1, T_2, \ldots, T_t$ on $n_1, n_2, \ldots, n_t$ nodes. Then by induction, each of the $T_i$ corresponds to a 132-avoiding $n_i$-permutation ending with $n_i$. Now add $\sum_{j=i+1}^t n_j$ to all entries of the permutation $p_i$ associated with $T_i$, then concatenate all these strings and add $n$ to the end to get the permutation $p$ associated with $T$. This is clearly a bijection as the blocks of the first $n - 1$ elements determine the branches of $T$. □

\textbf{Example 2.} The permutation 341256 corresponds to the $\beta(0,1)$-tree with all labels equal to 0 shown in Figure 2.

![Figure 2](image)

An easy way to read off the corresponding permutation once we have its entries written to the corresponding nodes is the well-known preorder reading: for every node, first write down the entries associated with its children from left to right, then the entry associated with the node itself, and do this recursively for all the children of the node.

Note that such a $\beta(0,1)$-tree has only one branch if and only if the next-to-last element of the indecomposable 132-avoiding $n$-permutation corresponding to it is $n-1$. 
Let’s introduce some more notions before we attack the general case. An entry of a permutation which is smaller than all the entries by which it is preceded called a left-to-right minimum.

**Definition 2.** Two $n-$permutations $x$ and $y$ are said to be in the same class if the left-to-right minima of $x$ are the same as those of $y$ and they are in the same positions.

**Example 3.** 34125 and 35124 are in the same class since their left-to-right minima are 3 and 1, and they are located at the same positions. 3142 and 3412 are not in the same class.

**Proposition 1.** Each nonempty class $C$ of $n$-permutations contains exactly one 132-avoiding permutation.

**Proof:** Take all entries which are not left-to-right minima and fill all slots between the left-to-right minima with them as follows: in each step place the smallest element which has not been placed yet which is larger then the previous left-to-right minimum. The permutation obtained this way will be clearly 132-avoiding, and it will be the only one in this class because any time we deviate from this procedure, we create a 132-pattern.

**Definition 3.** The normalization $N(p)$ of an $n$-permutation $p$ is the only 132-avoiding permutation in the class $C$ containing $p$.

**Example 4.** If $p = 32514$, then $N(p) = 32415$.

**Definition 4.** The normalization $N(T)$ of a $\beta(0,1)$-tree $T$ is the $\beta(0,1)$-tree which is isomorphic to $T$ as a plane tree, with all labels equal to zero.

**Proposition 2.** A permutation $p$ is indecomposable if and only $N(p)$ is indecomposable.

**Proof:** Let $C$ be the class containing $p$, given by the set and position of its left-to-right minima. It is clear that if $p \in C$ is decomposable, then the only way to cut it in two parts (so that everything before the cut is larger than everything after the cut) is to cut it immediately before a left-to-right minimum $a$. Now if there is a left-to-right minimum $a$ so that it is in the $n+1 -$ath position, then all entries which are larger than $a$ must be placed on the left of $a$ and so all such permutations in $C$ are decomposable. If there is no such $a$, then for all left-to-right minima $m$, there will be an entry $b$ so that $m < b$ and $b$ is on the right of $m$ and so permutations in $C$ will not be decomposable.

**Corollary 1.** If $p$ is an indecomposable $n$-permutation, then $N(p)$ always ends with the entry $n$. 
Proof: Note that the only way for a 132-avoiding \( n \)-permutation to be indecomposable is for it to end with \( n \). Then the statement follows from Proposition 2.

Now we are in a position to prove our theorem about the number of indecomposable 1342-avoiding permutations.

\textbf{Theorem 1.} The number of indecomposable \( n \)-permutations which avoid the pattern 1342 is

\[
I_n(1342) = t_n = 3 \cdot 2^{n-1} \cdot \frac{(2n)!}{(n+2)!n!}
\]

Proof: We are going to set up a bijection \( F \) between these permutations and \( D_n^{\beta(0,1)} \). This will be an extension of the bijection \( f \) of lemma 1. As the size of \( D_n^{\beta(0,1)} \) is known to be equal to \( t_n \), this will prove our claim.

Let \( p \) be an indecomposable 1342-avoiding \( n \)-permutation. Take \( N(p) \). By corollary 1 its last element is \( n \). Define \( F(N(p)) \) to be the \( \beta(0,1) \)-tree \( S \) associated to \( N(p) \) by the bijection of lemma 2. Now write the entries of \( p \) to the nodes of \( S \) so that for all \( i \), the \( p_i \) is written to the node where \( N(p)_i \) was written in \( S \). In particular, the left-to-right minima remain unchanged. Figure 3 shows how we associate the entries of the permutation 361542 to the nodes of \( N(T) \), which is the image of \( N(p) = 341256 \).

\begin{figure}[h]
\centering
\includegraphics{figure3}
\caption{Figure 3}
\end{figure}

Now we are going to define the label of each node for this new \( \beta(0,1) \)-tree \( T \) and obtain \( F(p) \) this way. (As an unlabeled tree, \( T \) will be isomorphic to \( S \), but its labels will be different). Denote \( i \) the \( i \)th node of \( T \) in the preorder reading, thus \( p_i \) is the \( i \)th entry of \( p \), (which is therefore associated to node \( i \)), while \( l(i) \) is the label of this node. We say that \( p_i \) \textit{beats} \( p_j \) if there is an element \( p_h \) so that \( p_h, p_i, p_j \) are written in this order and they form a 132-pattern. Moreover, we say that \( p_i \) \textit{reaches} \( p_k \) if there is a subsequence \( p_i, p_{i+a_1}, \cdots p_{i+a_t}, p_k \) of entries so that \( i < i+a_1 < i+a_2 < \cdots < i+a_t < k \) and that any entry in this subsequence beats the next one. For example, in the permutation 361542, the entry 6 beats 5 and 4,
5 beats 4 and 2, and 4 beats 2, while 6 reaches 2 (of course, each entry reaches all those elements it beats, too). Then let
\[ l(i) = \#\{ j \text{ descendants of } i \text{ (including } i \text{ itself) so that there is at least one } k > i \text{ for which } p_j \text{ reaches } p_k \} , \]
and let \( F(p) \) be the \( \beta(0,1) \)-tree defined by these labels. (Recall that a descendant of \( i \) is an element of the tree whose top element is \( i \)). First, it is easy to see that \( F \) indeed maps into the set of \( \beta(0,1) \)-trees: if \( v \) is an internal node and \( v_1, v_2, \ldots, v_k \) are its children, then \( l(v) \leq 1 + \sum_{i=1}^{k} l(v_k) \) because there can be at most one entry counted by \( l(v) \) and not counted by any of its children’s label, namely \( v \) itself. All labels are certainly nonnegative and all leaves, that is, the left-to-right minima, have label 0.

If \( p = 361542 \), then \( F(p) \) is the \( \beta(0,1) \)-tree shown in Figure 4b.

![Figure 4a](image1)

![Figure 4b](image2)

To prove that \( F \) is a bijection, it suffices to show that it has an inverse, that is, for any \( \beta(0,1) \)-tree \( T \in D_n^{\beta(0,1)} \), we can find the only permutation \( p \) so that \( F(p) = T \). We again claim that given \( T \), we can recover the node \( j \) which has the entry \( n \) of the preimage \( p \) associated to it, and so we can recover the position of \( n \) in the preimage.

**Proposition 3.** Suppose \( p_n \neq n \), that is, \( n \) is not associated to the root vertex. Then each ancestor of \( n \), including \( n \) itself, has a positive label. If \( p_n = n \), then \( l(n) = 0 \) and thus there is no vertex with the above property.

**Proof:** If \( p_n = n \), then nothing beats it, thus \( p_n = 0 \). Suppose \( p_n \) is not the root vertex.

To prove our claim it is enough to show that for any node \( i \) which is an an ancestor of \( j \), there is an entry \( p_k \) so that \( p_k \) is an ancestor of \( p_i \) and \( n = p_j \) reaches \( k \). Indeed, this would imply that the entry \( p_j = n \) is counted by the label \( l(i) \) of \( i \). Now let \( a_m = p_1 > a_2 > \cdots a_1 = 1 \) be the left-to-right minima of \( p \) so that \( n \) is located between \( a_r \) and \( a_{r+1} \). Then \( n \) certainly beats all elements located between \( a_r \) and \( a_{r+1} \) as \( a_r \) can play the role of 1 in the 132-pattern. Clearly, \( n \) must beat at least one entry \( y_1 \) on the right of \( a_{r+1} \) as well, otherwise \( p \) would be decomposable by cutting
it right before $a_{r+1}$. If $y_1$ is on the right of $i$, then we are done. If not, then $y_1$ must 
beat at least one entry $y_2$ which is on the other side of $a_{r_1+1}$, where $y$ is located 
between $a_{r_1}$ and $a_{r_1+1}$ for the same reason, and so on. This way we get a subsequence 
y_1, y_2, \cdots$ so that $n$ reaches each of the $y_i$, and this subsequence eventually gets to 
the right of $i$, since in each step we bypass at least one left-to-right minimum. Thus 
the proposition is proved.

\[\]

**Proposition 4.** Suppose $p_n \neq n$. Then $n$ is the leftmost entry of $p$ which has the 
property that each of its ancestors has a positive label.

**Proof:** Suppose $p_k$ and $n$ both have this property and that $p_k$ is on the left of $n$. (If 
there are several candidates for the role of $p_k$, choose the rightmost one). If $p_k$ beats 
an element $y$ on the right of $n$ by participating in the 132-pattern $x p_k y$, then $x p_k n y$ 
is a 1342-pattern, which is a contradiction. So $p_k$ does not beat such an element $y$. 
In other words, all elements after $n$ are smaller than all elements before $p_k$. Still, $p_k$ 
must reach elements on the right of $n$, thus it beats some element $v$ between $p_k$ and $n$. 
This element $v$ in turn beats some element $w$ on the right of $n$ by participating 
in some 132-pattern $t v w$. However, this would imply that $t v n w$ is a 1342-pattern, 
a contradiction, which proves our claim. \qed

Therefore, we can recover the entry $n$ of $p$ from $T$. Then we can proceed as in the 
proof of Lemma 1, that is, just delete $n$, subtract 1 from the labels of its ancestors 
and iterate this procedure to get $p$. If any time during this procedure we find that 
the current root is associated to the maximal entry that hasn’t been associated to 
other vertices yet, and the tree has more than one branch at this moment, then 
deleting the root vertex will split the tree into smaller trees. Then we continue the 
same procedure on each of them. The set of the entries associated to each of these 
smaller trees is uniquely determined because $T$ as an unlabeled tree determines the 
left-to-right minima of $p$. Therefore, we can always recover $p$ in this way from $T$. 
This proves that $F$ is a bijection.

Thus we have set up a bijection between the set of indecomposable 1342-avoiding 
n-permutations and $D_n^{\beta(0,1)}$. We know from [3] that $|D_n^{\beta(0,1)}| = t_n = 3 \cdot 2^{n-1} \cdot \frac{(2n)!}{(n+2)!n!}$ 
and therefore the Theorem is proved. \qed

Note that in particular, $F$ maps 132-avoiding permutations into $\beta(0,1)$-trees with 
all labels equal to 0 and permutations starting with the entry 1 into $\beta(0,1)$-trees 
consisting of a single path.

**Corollary 2.** $S_n(1342)$ equals the number of plane forests on $n$ vertices in which 
each component is a $\beta(0,1)$-tree.
3. Enumerative results

Tutte \cite{Tutte_1960} has obtained the numbers \( t_n \) by first computing a translate of their generating function
\[
F(x) = \sum_{n=1}^{\infty} 3 \cdot 2^{n-1} \cdot \frac{(2n)!}{(n+2)!n!} x^n = \frac{8x^2 + 12x - 1 + (1 - 8x)^{3/2}}{32x}. \tag{4}
\]
By theorem \cite{Tutte_1960}, the coefficients of this generating function are the numbers \( I_n \). Therefore, the generating function of all 1342-avoiding permutations is given by the following theorem.

**Theorem 2.** Let \( s_n = S_n(1342) \) and let \( H(x) = \sum_{n=0}^{\infty} s_n x^n \). Then
\[
H(x) = \sum_{i \geq 0} F_i(x) = \frac{1}{1 - F(x)} = \frac{32x}{-8x^2 + 12x + 1 - (1 - 8x)^{3/2}}. \tag{5}
\]

**Proof:** Any 1342-avoiding permutation has a unique decomposition into indecomposable permutations. This can consist of 1, 2, \cdots blocks, implying that \( s_n = \sum_{i=1}^{n} t_i s_{n-i} \), and the statement follows.

**Theorem 3.** For all \( n \geq 0 \) we have
\[
S_n(1342) = S_n(1342) = \frac{(7n^2 - 3n - 2)}{2} \cdot (-1)^{n-1} + 3 \sum_{i=2}^{n} 2^{i+1} \cdot \frac{(2i-4)!}{i!(i-2)!} \left( \frac{n-i+2}{2} \right) (-1)^{n-i}. \tag{6}
\]

**Proof:** Multiply both the numerator and the denominator of \( H(x) \) by \((-8x^2 + 20x + 1) + (1 - 8x)^{3/2}\). After simplifying we get
\[
H(x) = \frac{(1 - 8x)^{3/2} - 8x^2 + 20x + 1}{2(x + 1)^3}. \tag{7}
\]
As \((1 - 8x)^{3/2} = 1 - 12x + \sum_{n \geq 2} 3 \cdot 2^{n+2} x^n \frac{(2n-4)!}{n!(n-2)!} \), formula (6) implies our claim.

So the first few values of \( S_n(1342) \) are 1, 2, 6, 23, 103, 512, 2740, 15485, 91245, 555662. In particular, one sees easily that the expression on the right hand side of (6) is dominated by the last summand; in fact, the alternation in sign assures that this last summand is larger than the whole right hand side if \( n \geq 8 \). As \( \frac{(2n-4)!}{n!(n-2)!} < \frac{n^{n-2}}{n^{n-2}} \) by Stirling’s formula, we have proved the following exponential upper bound for \( S_n(1342) \).

**Corollary 3.** For all \( n \), we have \( S_n(1342) < 8^n \).

It is straightforward to check that the numbers \( I_n = t_n \) satisfy the following recurrence
\[
t_n = (8n - 4)t_{n-1}/(n + 2). \tag{8}
\]
In particular, $\sqrt{t_n} \to 8$. Using this formula we can disprove a conjecture of Stanley claiming that for all permutation patterns $q$ of length $k$, the sequence $\sqrt{n}S_n(q)$ converges to $(k - 1)^2$.

**Theorem 4.** $\sqrt{s_n} = \sqrt{S_n(1342)} \to 8$ when $n \to \infty$.

**Proof:** This is true as clearly $t_n \leq s_n < 8^n$ by Corollary 3 and we know from (8) that $\sqrt{t_n} \to 8$ if $n \to \infty$. \qed

**Corollary 4.** $\lim_{n \to \infty} (S_n(1342)/S_n(1234)) = 0$.

**Proof:** Follows from $\lim_{n \to \infty} \sqrt{S_n(1234)} = 9$ \cite{8} \cite{11}.

This Corollary certainly implies that $S_n(1342) < S_n(1234)$ if $n$ is large enough. However, using the formulae of Theorem 3 and \cite{8}, we can easily show that this is true for all $n \geq 6$ (This has recently been shown by a long argument in \cite{11}).

**Corollary 5.** For all $n \geq 6$, we have $S_n(1342) < S_n(1234)$.

**Proof:** It is known \cite{8} that

$$S_n(1234) = 2 \cdot \sum_{i=0}^{n} \binom{2i}{i} \cdot \binom{n}{i}^2 \cdot \frac{3k^2 + 2k + 1 - n - 2kn}{(k+1)^2(k+2)(n-k+1)}$$

(9)

One sees easily that the dominant summand is the one with $i = 2n/3$, and that this summand is much larger than the last (and dominant) summand in (3) if $n \geq 9$. The proof then follows by checking the values of $S_n(1342)$ and $S_n(1234)$ for $n \leq 8$. \qed

Formula (5) enables us to prove that the sequence $S_n(1342)$ is $\mathcal{P}$-recursive in $n$, solving an instance of the conjecture of Zeilberger and Noonan mentioned in the Introduction. Indeed, $H(x)$ is certainly algebraic, thus in particular, it is $d$-finite and therefore $S_n(1342)$ is $\mathcal{P}$-recursive as claimed. So we have proved the following theorem.

**Theorem 5.** The sequence $S_n(1342)$ is $\mathcal{P}$-recursive in $n$. Furthermore, its generating function $H(x)$ is algebraic and its only irrationality is $\sqrt{1-8x}$.

ACKNOWLEDGEMENT

I am grateful to my research advisor Richard Stanley and to Robert Cori who indicated me very useful references, as well as to Gilles Schaeffer who sent me the preprint \cite{5}. I am also indebted to Sergey Fomin for his helpful remarks and suggestions.
