MODIFIED HEIDELBERG TECHNIQUE FOR PANCREATIC ANASTOMOSIS

From the Department of Gastrointestinal Surgery, Hepatopancreatobiliary Unit, Federal University of Maranhão (Department of Gastrointestinal Surgery, Hepatopancreatobiliary Unit, Federal University of Maranhão), São Luiz, MA, Brazil; Department of Surgical Oncology, Tata Memorial Centre Hospital, Mumbai, India.

ABSTRACT: Background: Pancreatic fistula is a major cause of morbidity and mortality after pancreaticoduodenectomy. To prevent this complication, many technical procedures have been described. Aim: To present a novel technique based on slight modifications of the original Heidelberg technique, as new pancreatojejunostomy technique for reconstruction of pancreatic stump after pancreaticoduodenectomy and present initial results. Method: The technique was used for patients with soft or hard pancreas and with duct size smaller or larger than 3 mm. The stitches are performed with 5-0 double needle prolene on the posterior and anterior aspect of the pancreatic parenchyma with the jejunal seromuscular layer. A plastic stent, 20 cm long, is inserted into the pancreatic duct and extended into the jejunal lumen. Two previously placed hemostatic sutures on the superior and inferior edges of the remnant pancreatic stump are passed and tied. Results: Seventeen patients underwent pancreatojejunostomy after pancreaticoduodenectomy for different causes. None developed grade B or C pancreatic fistula. Biochemical leak according to the new definition (International Study Group on Pancreatic Surgery) was observed in four patients (23.5%). No mortality was observed. Conclusion: Early results of this technique confirm that it is simple, reliable, easy to perform, and easy to learn. This technique is useful to reduce the incidence of pancreatic fistula after pancreaticoduodenectomy.

RESUMO: Racional: Fístula pancreática é a principal causa de morbidade e mortalidade após duodenopancreatectomia. Muitos procedimentos técnicos têm sido descritos para prevenir este complicação. Objetivo: Apresentar uma nova técnica baseada em pequenas modificações sobre a técnica original de Heidelberg para pancreatojejunostomia na reconstrução do coto pancreático após duodenopancreatectomia e apresentar os resultados iniciais. Método: Esta técnica foi utilizada para pacientes com pancreas de consistência firme ou amolecida e ducto pancreático maior ou menor que 3 mm. Os pontos são realizados com prolene 5-0, duas agulhas nas posições de 2, 4, 6, 8, 10 e 12 h, com espessura total no parênquima pancreático. Uma sutura contínua é realizada com prolene 4-0 de agulha única na parede posterior e anterior do pâncreas com a camada seromuscular do jejuno. Uma sonda de silicone de 20 cm de comprimento é inserida no ducto pancreático em direção ao jejuno. As duas suturas hemostáticas previamente colocadas nas bordas superior e inferior do remanescente pancreático são passadas e amarradas com a camada seromuscular do jejuno. Resultados: Dezessete pacientes foram submetidos a pancreatojejunostomia após duodenopancreatectomia por diferentes causas. Nenhum desenvolveu fistula pancreática graus B ou C. Vazamento bioquímico, de acordo com a nova definição do Grupo Internacional de Estudo em Cirurgia do Pâncreas (ISGPS), foi observado em quatro pacientes (23,5%). Não houve mortalidade. Conclusão: Os resultados iniciais desta técnica confirmam que é simples, confiável, fácil de realizar e de aprender. Ela é útil para reduzir a incidência de fistula pancreática após duodenopancreatectomia.

INTRODUCTION

Pancreatic fistula is a frustrating complication and remains a major cause of morbidity and mortality after pancreaticoduodenectomy. The current literature reports that the incidence of this complication ranges between 3-45%, with a high associated mortality rate. To prevent pancreatic fistula, various technical procedures have been described, including invagination technique, duct-to-mucosa, Blumgart technique, Peng technique, and modifications. The desirable one should be associated with a low rate of pancreatic fistula and ease to perform regardless of the texture of the pancreas and the duct diameter.11,12,13,14

Technical aspects of the pancreatic anastomosis contribute to increasing the anastomotic failure rate, particularly in patients with soft pancreas and small pancreatic duct. Shrikhande and the Heidelberg group published 10 years ago an interesting technique of pancreatic anastomosis after pancreaticoduodenectomy.11,12,16

The objective of this study was to introduce a small modification of the Heidelberg pancreatojejunostomy technique for reconstruction of the pancreatic stump after pancreaticoduodenectomy that can be used in patients with soft or hard pancreas and with duct size smaller or larger than 3 mm.
METHOD

Technique

Transcetion of the pancreas

Two stay sutures (Prolene 4-0, Ethicon®) are placed on both the superior and inferior margins of the pancreatic remnant (hemostatic sutures). The pancreatic parenchyma is then transected with a sharp knife, and hemostasis is performed with electrocautery (Figure 1A). After the resection phase by subtotal stomach-preserving pancreatectoduodenectomy, the technique is completed and the specimen is retrieved. Then, a jejunal single limb is moved to the pancreatic cut end by a trans-mesocolic route and prepared for the anastomosis.

Mobilization of the pancreatic remnant

After the main pancreatic duct is identified, the cut surface of the pancreatic remnant is mobilized for approximately 1.5-2 cm of the length away from the splenic vein to allow the anastomosis. Small vessel branches are dissected and ligated (Figure 1A).

Posterior duct-pancreatic suture

Three sutures are placed on the posterior wall of the pancreatic duct to the posterior pancreatic parenchyma. The stitches are performed with 5-0 double needle prolene (Ethicon®) at the 4 o’clock, 6 o’clock, and 8 o’clock positions. The suture starts into the pancreatic duct traversing the full thickness of the parenchyma, until the posterior wall of the pancreas (from inside to outside). The free margin of the suture is at least 1 cm (Figure 1B).

Anterior duct-pancreatic suture

When all the posterior stitches are placed, three sutures are passed on the anterior wall of the pancreatic duct. The suture starts into the pancreatic duct, traversing the full thickness of the parenchyma, to the anterior wall of the pancreas (from inside to outside), similar to the posterior wall, at the 10 o’clock, 12 o’clock, and 2 o’clock positions. The posterior and anterior duct-pancreatic sutures are not knotted at this point (Figure 1C).

Posterior outer layer

In this step, the anterior and posterior duct-pancreatic sutures are suspended with a Kelly clamp. The pancreatic stump and the anti-mesenteric border of the jejunum are located face to face. Is performed a running suture with 4-0 single needle prolene (Ethicon®) on the posterior aspect the pancreatic parenchyma with the jejunal seromuscular layer, beginning at the lower edge of the pancreas toward the upper edge (Figure 1D).

Posterior inner layer

The jejunum is now opened on the anti-mesenteric side by electrocautery. The length of the enterotomy is approximately 0.5 cm long, near the pancreatic duct. The sutures in the 4 o’clock, 6 o’clock, and 8 o’clock positions (posterior duct-pancreatic suture) are passed from outside to inside in the inferior edge of the jejunum at the same positions (full thickness of the jejenum). The sutures are knotted at this time (Figure 1E).

Stent into the pancreatic duct

A plastic stent, 20 cm long, is inserted into the pancreatic duct and, if necessary, secured with absorbable suture at the opening of the pancreatic duct. Approximately 15 cm of the length of the stent is extended into the jejunal lumen.

Anterior inner layer

The sutures in the 10 o’clock, 12 o’clock, and 2 o’clock positions (anterior duct-pancreatic suture) are passed from inside to outside in the superior edge of the jejunum (full thickness of the jejenum) and are knotted with the plastic stent into the jejunal lumen (Figure 1F).

Anterior outer layer

A running suture is performed with 4-0 single needle prolene (Ethicon®), on the anterior aspect of the pancreatic...

parenchyma with jejunal seromuscular layer, beginning at the upper edge of the pancreas toward the lower edge (Figure 1G).

Stay suture with the jejenum

Finally, the two previously placed hemostatic sutures on the superior and inferior edges of the remnant pancreatic remnant are passed in the jejunal seromuscular layer and tied. These additional interrupted sutures placed between the pancreatic tissue and the jejunum must reinforce the anastomosis.

Hepaticojejunostomy is performed with interrupted absorbable suture and gastrojejunostomy is performed by antecolic route, approximately 50 cm proximal to the hepaticojejunostomy. All patients have two drains placed near the pancreato-jejunal anastomosis during the surgery.

RESULTS

In the period from July 2016 to June 2017, a total of 17 patients underwent pancreatoduodenectomy with this technique. The characteristics of the patients are presented in Table 1. There were 13 women (76.5%), and the median patient age was 54.1 years (20-76). Ductal adenocarcinoma was observed in nine patients (52.9%); soft texture of the pancreas was present in six (35.2%); duct size larger than 3 mm was found in nine (52.9%). Increased amylase in abdominal drainage (biochemical leak) was identified in four patients (23.5%) and resolved spontaneously within a week. Grade B or C fistula was not observed. No mortality occurred in this series.

DISCUSSION

Pancreatic fistula is one of the most severe complications after pancreatoduodenectomy. The incidence is 3-45%, and results in a high rate of related mortality. To avoid this life-threatening complication, several techniques of pancreaticoenteric anastomosis have been described, and the two primary methods are the duct-to-mucosa technique and the invagination technique. The procedures can be performed with the stomach or jejunum. Although some studies suggest that pancreatocolostomy is superior to pancreatojejunostomy, the ISGPS recommends pancreatocolostomy or pancreatojejunostomy for the pancreaticoenteric anastomosis.

Many factors have been associated with failure of the pancreaticoenteric anastomosis, including general factors, pathological factors, and technical factors. The most important risk factors related to pancreatic fistula are the diameter of pancreatic duct of 3 mm or smaller and the soft texture of the pancreas. In these situations, the type of pancreaticoenteric anastomosis is important to reduce pancreatic fistula.

The ideal pancreaticoenteric anastomosis should have the following characteristics: a) good blood supply to the pancreatic stump; b) pancreatic juice flow into the intestinal or gastric lumen; c) suitable for all pancreatic stumps and all pancreatic ducts; d) easy to perform and to easy to learn.

Was described a novel technique for pancreatic anastomosis after pancreatoduodenectomy. The pancreaticoenteric anastomoses were all performed by a team of surgeons who were trained in the performance of the pancreaticoenteric anastomosis by the senior surgeon (OJMT). The novel pancreaticojejunostomy presented in this study differs slightly from the original technique published by Shrikhande et al., and low rates of pancreatic fistula have been observed with the original technique.

According to the ISGPS’s new definition and grading of postoperative pancreatic fistula, grade A pancreatic fistula is now biochemical leak. In the present study with the first unselected, consecutive series, none of patients developed grade B or C pancreatic fistula, and biochemical leak was observed in four patients (23.5%) after this technique.

The series presented in this study demonstrates low rates of pancreatic fistula in comparison with other recent technical modifications in the literature (Table 2).

In the current study, was analyzed the drain amylase, which was elevated in 23.5% of the patients (biochemical leak) according to the new ISGPS definition. Risk factors such as pancreatic duct size of 3 mm or smaller and soft texture of the pancreatic parenchyma were observed in the present series, but the same technique was suitable even for these patients.

In this technique, the six interrupted stitches, anterior and posterior full thicknesses, involve more pancreatic tissue. In addition, the stump is covered with the jejunum, reducing the risk of rupture. The length of the jejunojunostomy is approximately 0.5 cm long, smaller than that described by Shrikhande et al., and is adjustable based on the diameter of the pancreatic duct. In addition, was inserted a plastic stent into the pancreatic duct to achieve better internal drainage from the pancreas to the intestinal lumen. Stents are not used in the original technique, and the diameter depends on the size of the duct. This procedure avoids or reduces pancreatic juice and bile retention in the initial segment of the jejunum when the peristaltic function is not restored. Furthermore, the procedure decreases the incidence of stricture formation around the pancreatic duct and reduces the possibility of inadvertent pancreatic duct occlusion. There is no need to remove the internal drainage stent. At the end of the procedure, after the anastomosis is completed, the stay suture is used to anchor the gland to the jejunum. This modification reduces pressure on the anastomosis suture line.

In the classical “duct-to-mucosa” anastomosis, the sutures involve a small portion of the pancreatic duct and the mucosa of the jejunum, but the pancreatic tissue is not included. The risk to tear and cause anastomotic rupture is relatively high.

TABLE 2 - Results of other technical modifications

| Author          | Fistula | Grade A | Grade B | Grade C | Mortality |
|-----------------|---------|---------|---------|---------|-----------|
| Kim et al.      | 37.1%   | 17.9%   | 15.2%   | 4.0%    | 4.6%      |
| Gröbmyer et al. | 20.3%   | 13.4%   | 3.7%    | 3.2%    | 1.6%      |
| Chen et al.     | 24.5%   | 18.9%   | 5.6%    | 0.0%    | 0.0%      |
In invagination pancreatojejunostomy, part of the pancreatic stump is invaginated into the lumen of the jejunum. The stitches are placed in the pancreatic parenchyma and capsule, but not in the pancreatic duct with the risk of laceration on tying. The pancreatic surface is exposed to the intestinal or gastric lumen, and hemorrhagic complications can occur. Furthermore, this technique is not suitable for patients with a large pancreatic stump.

Our modification of the original technique described by Shrikhande et al. seems to be safe for soft or hard pancreas and any size of pancreatic duct. The small number of patients with this new pancreateoenteric anastomosis is the limitation of this study, and others are necessary to assess the utility of this procedure in decreasing postoperative fistula rates.

**CONCLUSION**

Early results of this technique confirm that it is simple, reliable, easy to perform, and easy to learn. This technique is useful to reduce the incidence of pancreatic fistula after pancreatectomy.
