Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Biosurfactants and anti-inflammatory activity: A potential new approach towards COVID-19
Mohana Devi Subramaniam¹, Dhivya Venkatesan², Mahalaxmi Iyer³, Sarathbabu Subbarayan⁴, Vivekanandhan Govindasami⁵, Ayan Roy⁶, Arul Narayanasamy⁷, Siva Kamalakannan⁸, Abilash Valsala Gopalakrishnan⁹, Raviminickam Thangarasu¹⁰, Nachimuthu Senthil Kumar⁴ and Balachandar Vellingiri²

Abstract
Coronavirus disease 2019 (COVID-19) has grown to be global public health emergency. The biosurfactants (BSs) are surface-active biomolecules with unique properties and wide applications. Several microbes synthesize secondary metabolites with surface–active properties, which have a wide range of anti-inflammatory and anti-viral roles. The monocytes and neutrophils are activated by bacteria, which subsequently result in high secretion of pro-inflammatory cytokines (TNF-α, IL-6, IL-8, IL-12, IL-18 and IL-1β) and toll-like receptors-2 (TLR-2). Following the inflammatory response, BSs induce the production of cationic proteins, reactive oxygen species (ROS) and lysozyme, and thus can be used for therapeutic purposes. This article provides recent advances in the anti-inflammatory and antiviral activities of BSs and discusses the potential use of these compounds against COVID-19, highlighting the need for in-vitro and in-vivo approaches to confirm this hypothesis. This suggestion is necessary because there are still no studies that have focused on the use of BSs against COVID-19.

SARS-CoV-2, Biosurfactants (BSs), Immunomodulatory, Microorganisms, Cytokine storm.

Introduction
Surfactants are molecules with amphipathic properties having hydrophilic and hydrophobic moieties that reduce surface and interfacial tension between liquids or biphasic systems as liquid/gas, liquid/liquid and solid/liquid. Based on the origin, the surfactants have been classified into chemical surfactants and biosurfactants (BSs) [1]. BSs are secondary metabolites obtained from several microorganisms including bacteria, fungi and yeasts; classified based on their chemical composition and their origin from microbes, including Pseudomonas aeruginosa, Bacillus subtilis and Lactobacillus sp. [2]. They are attached either intracellularly or extracellularly during growth [3]. BSs are used in a wide range of applications since it is eco-friendly and biodegradable than synthetic surfactants. In recent years, this has attracted broad interest due to their unique properties like specificity, low toxicity and smooth preparation. These properties have gained attention in broad areas of cleaning and other applications for commercialization [4]. The unique features of BS opted for industrial applications such as petroleum, fertilizers, cosmetics,

Coronavirus disease 2019 (COVID-19), caused by a new strain of coronavirus emerged in December 2019 and became a global pandemic. The COVID-19 has grown to be a global public-health emergency [7,8]. The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a new member of the genus beta coronavirus, which exhibits faster human-to-human transmission leading to a worldwide public health emergency [7,8]. Once infected, the patient mainly relies on the immune system to resist SARS-CoV-2, with the supportive treatment being prescribed if complications occur [9]. Meanwhile, scientists confirmed that the first step in the SARS-CoV-2 pathogenesis is the specific interaction of the virus with angiotensin-converting enzyme 2 (ACE2), a master regulator of the renin–angiotensin system of host cells through its spike protein [10]. Once the virus enters the lungs, the immune system sends a large number of immune cells to kill the virus [11]. Once the cytokine storm is formed, the immune system is exaggerated and kills the healthy cells [12]. Besides, the ability of the virus to evade, the immune system is hugely problematic when considering appropriate treatment and vaccine options. SARS-CoV-2 debilitates the equilibrium maintained by the immune system and triggers the cytokine storm. The significant difficulties found in COVID-19 patients have been linked to the cytokine storm. In-depth research is required to effectively manage the cytokine storm while maintaining the immune system balance. On binding, the spike protein is cleaved into two, and this induces a conformational change facilitating the fusion of the virus and its entry into the cell. Recently, Vellingiri et al. [6] comprehensively discussed about the viral transcription, translation and expression of viral proteins in the cells. BSs in medical application has elevated during the past decade. BS acts as a therapeutic agent due to its anti-viral, anti-bacterial and anti-fungal property in fighting many diseases [13]. Hence, this review focuses on the anti-inflammatory and anti-viral properties of the BSs, and its potential uses against as a strategy to treat or prevent COVID-19 disease.

**Anti-inflammatory potential of biosurfactants**

Phospholipase A$_2$ (PLA$_2$) functions in arachidonic acid (AA) secretion. Various types of PLA$_2$ collectively called as cytosolic phospholipase-A2 (cPLA$_2$). Inflammatory response occurs due to the release of AA that is converted to inflammatory mediators. AA acts as a precursor of eicosanoids secretion, which functions in maintenance of inflammatory process. Mechanistically, structural features of BSs were detected by toll like receptors (TLR-2), and the BSs communicate with the cell membranes and macromolecules and inhibit cPLA$_2$ that initiate anti-inflammatory responses. In an in vitro model, the pro-inflammatory cytokines were secreted by neutrophils when induced with trehalolipids synthesized by *Rhodococcus ruber* [14]. The glycolipids from *R. ruber* were induced in mononuclear cells, and it was revealed to mediate the production of interleukin-12 (IL-12), interleukin-18 (IL-18) and reactive oxygen species (ROS) [15] and stimulated the production of TNF-α, IL-1β and IL-6 [16]. Administration of surfactin in rat and fish models decreased the pro-inflammatory cytokines with an increase in the levels of anti-inflammatory cytokines [17,18]. The BS surfactin from *Bacillus subtilis* was observed to suppress lipopolysaccharide-induced signaling pathways, impaired macrophage function and IL-12 expression, decreased TLR-4 protein expression with an increase in the anti-inflammatory effect [19]. Surfactin from *Staphylococcus aureus* significantly reduced the pro-inflammatory cytokines, obstructed the lipoteichoic acid–induced signaling pathway, increased STAT3 phosphorylation and blocked the expression of heme oxygenase-1 (HO-1). It has been established that surfactin as an anti-inflammatory and neuroprotective agent [20]. Similarly, limited studies were conducted, and they revealed the potential effect of BSs from yeast species with anti-inflammatory activity. Sophorolipids (SLs) from *Candida bombicola* decreased immunoglobulin...
E (IgE) level, mRNA expression of TLR-2, IL-6 and STAT3 and lung inflammation [21,22]. Hence, the study demonstrated that SLs downregulate the IgE coding genes, thereby acting as an anti-inflammatory agent and potential therapeutic compound [21,23]. In an experimental rat model, SLs reduced sepsis-related mortality and observed predicted to display anti-inflammatory effects [24,25]. Similarly, in another rat model study, SLs resulted in an improved survival rate, decreased nitric oxide and modulated inflammatory responses [26]. Natural and synthetic SLs were demonstrated to show a prominent anti-inflammatory activity, spermicidal and anti-HIV activity [27]. The SLs reduce the expression of inflammatory cytokines [25] and these findings indicate that SLs would be a promising therapy for anti-inflammatory or immunomodulation in chronic inflammatory conditions. Mannosylerythritol lipids are secreted by *Pseudomonas antarctica*, which has also inhibited the inflammatory mediators, thereby creating anti-inflammatory action [28]. From these studies, it is clarified that the BSs from bacterial and yeast species showed an anti-inflammatory activity and suggested to be potential therapeutic candidate in treating inflammatory diseases. Also, more studies need to be conducted on the effects of anti-inflammation using these BSs.

**Biosurfactants anti-inflammatory role against COVID-19**

Once the SARS-CoV-2 enters the human host cell through the ACE2 receptors, immediately the immune system deploys a large number of immune cells to respond against the virus especially by recruiting the antigen-presenting cells [29]. It is reported that the COVID-19-positive patients have high levels of cytokine storm, which are also correlated with the viral load in COVID-19 patients [30]. When the cytokine storm is formed, the immune system is exaggerated and kills healthy cells [12]. Moreover, when the levels of IL-6 and lymphocytes are higher, they inadvertently result in increased pulmonary damage [31]. In addition to this, the ability of the virus to evade the immune system is hugely problematic when considering appropriate treatment and vaccine options. The subsequent damage can be caused either by direct infection of SARS-CoV-2 in cells, by hypoxemia due to lung damage or by an indirect injury caused by the immune and cytokine responses [32]. Excessive amounts of cytokines, such as
IL-1β and IL-18, are produced during the cytokine storm and may cause irrevocable damage to various organs. It is well known that the BSs have a major role in defense against pathogenic infection as well as induce anti-inflammation in the human body [33]. The glycolipid and lipopeptide types of BSs have been effectively used towards treating various anti-microbial diseases [34]. One of its types, the surfactin, which is a natural cyclic lipopeptide, has shown to have various biological properties like anti-viral, anti-fungal and anti-cancer, which is initiated by suppressing the signaling of cell survivals, platelet aggregation and reducing the cytokine storm by proposing anti-inflammatory effects [35]. Hence, the use of BS would be a possible way to minimize the impact of cytokine storm caused due to SARS-CoV-2 infection in the COVID-19-affected patients. We propose a hypothetical mechanism of action of BS in reducing the inflammation in the COVID-19 disease. On binding of the SARS-CoV-2’s the S (Spike) protein, it is cleaved into two; this induces a conformational change facilitating the fusion of the virus and its entry into the cell. The NF-κB pathway is a common pathway implicated in many pathologies and is activated by viral N, S, 3a and 7a proteins. NF-κB, on activation, enters the nucleus and catalyses the transcription of pro-IL-1β and procaspase-1. When additional signals like increased Ca²⁺ and ROS are detected, the pro-IL-1β and procaspase 1 are cleaved into IL-1β and caspase 1. This results in the production of cytokines such as (TNF-α, IL-1β, IL-6, IL-2) and causes a cytokine storm that results in necrosis and cell death. In COVID-19 patients, it is observed that there is an inhibition in the production of heme, as it is responsible for the production of biliverdin, ferrous iron and carbon monoxide, which could limit the inflammation and stress caused due to SARS-CoV-2 viral infection [36–38]. If the BS is provided to the COVID-19 patients, then it could suppress the production of NF-κB by stimulating the HO-1 and TH1 macrophage cells [39]. This, in turn, would reduce the production of cytokines such as (TNF-α, IL-1β, IL-6, IL-2), which will reduce the effect of cytokine storm in the COVID-19 patients. This possible mechanism has been depicted in Figure 1. Even it has been reported that as the BSs are known for its

(continued on next page)
emulsification role in drugs or vaccines would be highly successful as they are produced naturally, which contains non-toxic and non-pyrogenic immunological adjuvants when mixed with conventional antigens for treating COVID-19 disease [40]. Hence, these pieces of evidence show that BSs play a huge role as immunosuppressive agents and could be highly used as a combinational drug to relieve inflammatory responses caused due to SARS-CoV-2 infection.

**Biosurfactants anti-viral activity against COVID-19**

Certain BSs inactivates viruses due to physio–chemical reactions [41]. This hypothetical nature occurs only in enveloped viruses. Generally, it is stated that BSs disturb the viral membrane structures and disrupt the outer covering [27]. The hydrophilic nature of the BS occurs due to the presence of acetyl groups that promotes anti-viral activity [42]. Also, the hydrophobic nature with specific number of carbon atoms inactivates the virucidal effects [43]. High inactivation arises when the BS has a fatty acid chain with 15 carbon atoms and one negative charge; in addition, monomethyl esters showed viral inactivation in semliki forest virus [43]. The antiviral activity of BSs has been approved, and patents were obtained on treating various viruses [44–48]. Evidential reports from these studies can be applied in SARS-CoV-2 since it is an enveloped virus; hence, the mechanism of action has been explained as follows.

As the SARS-CoV-2 virus enters the host cell, the amphiphilic nature of BSs interacts with viral cell membrane and enters the bilayered lipid membrane that causes changes in permeability either by ion channel formation or disruption of the membrane system. A complete disintegration of the viral envelope and capsid protein occurs during high concentration of BSs. The disruptions of the lipid envelope and spike protein are encapsulated into micelles and results in viral inactivity. This micelle formation has the capability to function as liposomes that could deliver the drug to the infection site and also protects during hazardous conditions [49]. Hence, the nature of BSs to form as micelles would be an effective drug delivery system in treating SARS-CoV-2 infection. Also, BS does not affect the viral replication but inactivates the viral effects before adsorption or penetration. The mechanism of anti-viral activity by BS against SARS-CoV-2 is shown in Figure 2.

**Recommendations**

The COVID-19 disease, which is spreading vigorously, has become a global threat across the world. Discovery of any medicine or vaccine against this disease will be a kingmaker for the people suffering from this deadly infection. Hence, here we are recommending few products that will be produced using BS as a more potent way to get precautions or treatment from the
SARS-CoV-2 infection. The following are the guidelines:

- The BS has multi-purpose use in various fields such as food, pharmacology, cosmetics, detergents and so on. But its anti-inflammatory property would be a novel solution in targeting COVID-19 disease in multiple ways.
- As always, cleaning our hands will protect us from this virus. The strategy of using BS-encoded handwash or hand sanitizers promises to be a more protective shield against SARS-CoV-2 virus.
- The amphiphilic nature of the BS makes it easier to interact with SARS-CoV-2’s lipid bilayer and would enable the destruction of the viral genome, which would facilitate easy clearance of the virus.
- The propensity of BSs towards drug delivery is high, especially because of its emulsification property.
- Hence, if it is highly advisable that using or producing any drug from BSs along with conventional drugs or vaccines for COVID-19 will be beneficial because of its anti-viral and anti-inflammatory role against the SARS-CoV-2 virus.
- The list of clinical trials and ongoing trials about BSs as drugs against various respiratory disorders as well as for COVID-19 have been depicted in Table 2.
- As it is evident that BSs are eco-friendly and less toxic, it is recommended that its use in house-hold cleaning products or detergents will target and kill the SARS-CoV-2 virus.
- Another way of incorporating the BS in targeting the virus is its use as a medicated chewing gum.
- Incorporation of the BSs from microbes along with Indian medicinal plants promises to be highly instrumental in clearing the viral load efficiently from the human body.

Conclusion and future perspectives

Immunologists are working relentlessly to determine the immunity against SARS-CoV-2 and how long it may last [50]. Tremendous effort has been focused on neutralizing the antibodies, which bind to the viral proteins that directly prevent infection. Studies found that levels of neutralizing antibodies against SARS-CoV-2 remain high for a few weeks after infection but then typically begin to wane. Various therapeutic approaches have been recently discussed for COVID-19 [51].

As always, cleaning our hands will protect us from this virus. The strategy of using BS-encoded handwash or hand sanitizers promises to be a more protective shield against SARS-CoV-2 virus.

- The amphiphilic nature of the BS makes it easier to interact with SARS-CoV-2’s lipid bilayer and would enable the destruction of the viral genome, which would facilitate easy clearance of the virus.
- The propensity of BSs towards drug delivery is high, especially because of its emulsification property.
- Hence, if it is highly advisable that using or producing any drug from BSs along with conventional drugs or vaccines for COVID-19 will be beneficial because of its anti-viral and anti-inflammatory role against the SARS-CoV-2 virus.
- The list of clinical trials and ongoing trials about BSs as drugs against various respiratory disorders as well as for COVID-19 have been depicted in Table 2.
- As it is evident that BSs are eco-friendly and less toxic, it is recommended that its use in house-hold cleaning products or detergents will target and kill the SARS-CoV-2 virus.
- Another way of incorporating the BS in targeting the virus is its use as a medicated chewing gum.
- Incorporation of the BSs from microbes along with Indian medicinal plants promises to be highly instrumental in clearing the viral load efficiently from the human body.

With the recent scenario to combat the pandemic situation, BSs from the microbial source could be anew move to.

This work was supported by the project funded by MHRD-RUSA 2.0 — BEICH; the Science and Engineering Research Board (SERB), Government of India [ECR/2018/000718]; the DBT, New Delhi sponsored Advanced Level State Biotech Hub (BT/04/NE/2009 Dr.29.082014), Mizoram University.

Declaration of competing interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this article.

Acknowledgements

Dr. VB would like to thank Bharathiar University for providing the necessary infrastructure facility and for providing necessary help in carrying out this review process and project funded by MHRD-RUSA 2.0 — BEICH of the manuscript; and Dr. SMD would like to thank the Science and Engineering Research Board (SERB) (ECR2018/000718), Government of India, New Delhi, for providing necessary help in carrying out this review process. Dr. NSK wish to thank the Advanced Level State Biotech Hub (BT/04/NE/2009 Dr.29.08.2014), Mizoram University, Aizawl, sponsored by the Department of Biotechnology (DBT), New Delhi, Government of India, for providing the infrastructural support and facilities.
