DOPPELGÄNGERS: BIJECTIONS OF PLANE PARTITIONS

ZACHARY HAMAKER, REBECCA PATRIAS, OLIVER PECHENIK, AND NATHAN WILLIAMS

Abstract. We say two posets are doppelgängers if they have the same number of $P$-partitions of each height $k$. We give a uniform framework for bijective proofs that posets are doppelgängers by synthesizing $K$-theoretic Schubert calculus techniques of H. Thomas and A. Yong with M. Haiman’s rectification bijection and an observation of R. Proctor. Geometrically, these bijections reflect the rational equivalence of certain subvarieties of minuscule flag manifolds. As a special case, we provide the first bijective proof of a 1983 theorem of R. Proctor—that plane partitions of height $k$ in a rectangle are equinumerous with plane partitions of height $k$ in a shifted trapezoid.

1. Introduction

1.1. Doppelgängers. Fix $P$ a finite partially-ordered set (poset) with order relation $\succeq$. For $\ell \in \mathbb{Z}_{\geq 0}$, a $P$-partition of height $\ell$ is a weakly order-preserving map $T : P \rightarrow \{0, 1, \ldots, \ell\}$. That is, if $p \succ q \in P$, then $T(p) \geq T(q)$. We write $PP^\ell(P)$ for the set of all $P$-partitions of height $\ell$ and—for ease of notation—we refer to $P$-partitions as plane partitions.

For $p \succ q \in P$, we say $p$ covers $q$—written $p \triangleright q$—if there is no $r \in P$ such that $p \succ r \succ q$. We draw the Hasse diagram of $P$ as a graph directed upwards in the page, with vertices indexed by the elements of $P$ and an edge from the vertex for $q$ to the vertex for $p$ when $p \triangleright q$.

Example 1.1. The posets with Hasse diagrams and each have six plane partitions of height 1, as illustrated below. Vertices in the Hasse diagrams are colored white if their image is 0 and gray if their image is 1.

*The number of plane partitions of height $\ell$ in a poset $P$ with $n$ elements is counted by its order polynomial $|PP^\ell(P)|$. As its name suggests, the order polynomial is a polynomial in $\ell$ of degree $n$ [Stu72, Section 13]. One can check that both posets from Example 1.1 have the same order polynomial:

$$|PP^\ell(\circ\circ) - PP^\ell(\circ\circ)| = \frac{1}{12} (\ell + 1)(\ell + 2)^2(\ell + 3).$$

Z.H. was supported by the Institute for Mathematics and its Applications with funds provided by the National Science Foundation.
R.P. was partially supported by NSF Grant DMS-1148634.
O.P. was supported by an Illinois Distinguished Fellowship and an NSF Graduate Research Fellowship.
This example motivates the following definition.

**Definition 1.2.** Let $P, Q$ be two finite posets. We say that $P$ and $Q$ are doppelgängers if they have the same order polynomial.

Here are some trivial examples: any poset is its own doppelgänger, as are any poset and its dual (obtained by reversing the order relation, which flips the Hasse diagram upside down). We can explain the doppelgängers in Example 1.1 with the simple observation that the poset obtained by adjoining a new minimal element to a poset $P$ is a doppelgänger with the poset obtained by adjoining a new maximal element to $P$.

### 1.2. Minuscule Doppelgängers.

We use the combinatorics of the $K$-theoretic Schubert calculus of minuscule flag varieties to bijectively establish certain pairs of posets $(\Lambda_X, \Phi_\Lambda^+)$ as doppelgängers in Theorem 1.3. As summarized in Section 2, our philosophy is that—given a ring with basis indexed by combinatorial objects and a combinatorial rule for computing structure coefficients—multiplicity-free products in that ring may be equivalently stated as bijections. In addition to providing two infinite families of doppelgängers, we also exhibit one non-trivial exceptional pair. The first poset $\Lambda_X$ in each pair is a poset that describes the Schubert cell decomposition of a minuscule flag variety (a minuscule poset, defined in Section 4); the second poset $\Phi_\Lambda^+$ is a poset on the positive roots of another, a priori unrelated, root system (defined in Section 8). To streamline our exposition, we defer the precise definitions and root-theoretic meanings of these posets until Sections 4 and 8, simply defining the posets for now by their Hasse diagrams in Figure 1.

| Label | Poset Name | Hasse Diagram | Hasse Diagram | Poset Name |
|-------|------------|---------------|---------------|------------|
| (B)   | $\Lambda_{Gr(k,n)}$ | ![Hasse Diagram](image1) | $n - 1$ | $\Phi_{B_{k,n}}^+$ |
| (H)   | $\Lambda_{OG(6,12)}$ | ![Hasse Diagram](image2) | $n - 2k + 1$ | $\Phi_{H_3}^+$ |
| (I)   | $\Lambda_{Q^{2n}}$ | ![Hasse Diagram](image3) | $2n - 1$ | $\Phi_{I_2(2n)}^+$ |

**Figure 1.** The names and Hasse diagrams of the six posets considered in Theorem 1.3. The first and last rows are infinite families, while the middle row is a single exceptional example.
Theorem 1.3. As defined in Figure 1, fix
\[(X,Y) \in \{ (\text{Gr}(k,n), B_{k,n}), (\text{OG}(6,12), H_3), (Q^{2n}, I_2(2n)) \} \].

Then, \( \Lambda_X \) and \( \Phi_Y^+ \) are doppelgängers. Moreover, there is an explicit, type-uniform bijection
\[ \text{PP}^{[\ell]}(\Lambda_X) \simeq \text{PP}^{[\ell]}(\Phi_Y^+) \].

Our arguments are usefully interpreted as statements about rational equivalence of certain generalized Schubert and Richardson subvarieties of minuscule flag varieties. That is, each of the bijections of Theorem 1.3 corresponds to the fact that a certain Richardson variety represents the same element of the Chow ring as a certain Schubert variety. Nonetheless, our statements and arguments are purely combinatorial and do not logically depend on these geometric considerations. In particular, the key proofs should be accessible to a reader who knows no geometry—such readers may skip reading Sections 3 to 5, 8 and 9, referring to them only for notation.

Although our bijections are type-uniform, our proofs are only partially so. It is an open problem to identify other interesting examples of doppelgängers, or to classify them in general.

Remark 1.4. The equality
\[ \left| \text{PP}^{[\ell]}(\Lambda_{\text{Gr}(k,n)}) \right| = \left| \text{PP}^{[\ell]}(\Phi_{B_{k,n}}^+) \right| \]
was first proven nonbijectively by R. Proctor in [Pro83] using a branching rule due to R. King from the Lie algebra inclusion \( \mathfrak{sp}_{2n}(\mathbb{C}) \hookrightarrow \mathfrak{sl}_{2n}(\mathbb{C}) \) [Kin75, Lit50]. Indeed, R. Proctor remarks that “the question of a combinatorial correspondence for [Equation (1.1)] seems to be a complete mystery.”

For the case \( \ell = 1 \) of Equation (1.1), J. Stembridge produced a jeu-de-taquin bijection [Ste86], while V. Reiner gave an argument using type \( B \) noncrossing partitions [Rei97]. For \( \ell \leq 2 \), S. Elizalde gave a bijection in the language of pairs of lattice paths [Eliz15]. No bijection was previously known for \( \ell > 2 \), and the restriction of our bijection is not immediately equivalent to any of these known special cases for \( \ell \leq 2 \).

Remark 1.5. The other cases of Theorem 1.3 are easy to establish directly [Wil13, Theorems 3.1.24 and 3.1.27]; in these cases, we provide the first bijections and the first geometric interpretations.

1.3. \( K \)-Theoretic Schubert Calculus. To interpret the examples of Figure 1 as statements in Schubert calculus, the key observation we make is that for
\[(X,Y) \in \{ (\text{Gr}(k,n), B_{k,n}), (\text{OG}(6,12), H_3), (Q^{2n}, I_2(2n)) \} , \]
both the posets \( \Lambda_X \) and \( \Phi_Y^+ \) simultaneously occur as subposets of a larger, ambient, minuscule poset \( \Lambda_Z \). We denote these two embeddings by
\[ \Theta(\Lambda_X) \subseteq \Lambda_Z \quad \text{and} \quad \chi(\Phi_Y^+) \subseteq \Lambda_Z . \]

As we explain in Section 9, the embedding of \( \Lambda_X \) into \( \Lambda_Z \) comes from an embedding of one root system in another, while the duals of \( \Phi_Y^+ \) appear as order ideals in \( \Lambda_Z \) and are posets on the positive roots of yet a third root system. Figure 2 lists the triples \((\Lambda_X, \Lambda_Z, \Phi_Y^+)\) corresponding to the doppelgängers in Figure 1, while specific examples of these poset embeddings are illustrated in Figure 3. In Figure 2,
the symbols $X$ and $Z$ specify a minuscule flag variety (Section 4), while the symbol $Y$ is a bookkeeping device that specifies a Coxeter-Cartan type (Section 8).

| Label | $\Lambda_X$ | $\Lambda_Z$ | rect | $\Phi_Y^+$ |
|-------|-------------|-------------|------|-------------|
| (B)   | $\Lambda_{\text{Gr}(k,n)}$ | $\Lambda_{\text{OG}(n,2n)}$ | $\Phi_{B_{k,n}}^+$ |
| (H)   | $\Lambda_{\text{OG}(6,12)}$ | $\Lambda_{\text{OG}(6,12)}$ | $\Phi_{H_3}^+$ |
| (I)   | $\Lambda_{Q^{2n}}$ | $\Lambda_{Q^{4n-2}}$ | $\Phi_{I_2(2n)}^+$ |

**Figure 2.** Triples $(X,Y,Z)$, where $\Lambda_X$ and $\Phi^+(Y)$ are doppelgängers. The symbols $X$ and $Z$ specify minuscule flag varieties, while $Y$ relates to a Coxeter-Cartan type. As illustrated in Figure 3, both the poset $\Lambda_X$ and the poset $\Phi^+_Y$ embed in the ambient minuscule poset $\Lambda_Z$; a tableau of shape $\Phi^+_Y$ is then obtained from one of shape $\Lambda_X$ by $K$-rectification.

**Figure 3.** Examples of simultaneous embedding of the doppelgänger pairs $\Lambda_X$ and (duals of) $\Phi^+_Y$ in the minuscule posets $\Lambda_Z$. The vertices with thick borders correspond to $\Theta(\Lambda_X)$, while the gray vertices represent $\chi(\Phi^+_Y)$.

These embeddings allow us to prove Theorem 1.3 using a combinatorial model of the structure coefficients of $K$-theoretic Schubert calculus on minuscule varieties. Our Theorem 7.2 and Theorem 7.1 give a much more general bijective framework for proving similar results.

In more detail, the increasing tableaux of shape $\mathcal{P}$ and height $m$—written $\text{IT}^{[m]}(\mathcal{P})$—are the strictly order-preserving maps from $\mathcal{P} \to \{1, 2, \ldots, m\}$. For a ranked poset $\mathcal{P}$ whose maximal chains are all of the same length $\text{ht}(\mathcal{P})$ (and, in particular, for all the posets of Figure 1), there is a simple bijection

$$\text{IT}^{[m]}(\mathcal{P}) \cong \text{PP}^{[\ell]}(\mathcal{P}),$$

where $m = \ell + \text{ht}(\mathcal{P})$ (see Proposition 6.2). The significant advantage that increasing tableaux enjoy over plane partitions is a well-developed theory of $K$-theoretic jeu-de-taquin that is particularly well-behaved on minuscule posets. This theory,
which we review in Sections 5 and 6, was introduced for geometric purposes by H. Thomas and A. Yong in [TY09b] and was further developed by A. Buch, E. Clifford, H. Thomas, M. Samuel, and A. Yong in [CTY14, BS16]. We only need its combinatorial features to prove Theorem 1.3: using the identification of increasing tableaux with plane partitions and the embeddings in Equation (1.2), the bijections of Theorem 1.3 are uniformly written
\[ IT^m(\Lambda_X) \to IT^m(\Phi^+_Y) \]
\[ T \mapsto \chi^{-1}(\text{rect}(\Theta(T))), \]
where \( \text{rect} \) is an operation called \( K \)-rectification defined using \( K \)-theoretic jeu-de-taquin.

Example 1.6. We continue Example 1.1 to give the bijection of Theorem 1.3 in the case
\[ \text{PP}^1(\Lambda_{Gr}(2,4)) \simeq \text{PP}^1(\Phi^+_B(2,4)). \]
After embedding both posets in \( \Lambda_{OG}(4,8) \), the bijection is given by the jeu-de-taquin computation illustrated below (for more details, see Section 6.2). A larger example with additional details is given in Section 1.4, and the boxed fillings in the middle two rows are explained in Remark 1.8.

1.4. Example: Rectangles and Shifted Trapezoids. For the impatient reader, in this section we give a detailed example of the bijection of Theorem 1.3
\[ \text{PP}^4(\Lambda_{Gr}(4,8)) \simeq \text{PP}^4(\Phi^+_B(4,8)). \]
A plane partition in \( \text{PP}^4(\Lambda_{Gr}(4,8)) \) can be drawn as an ordinary plane partition whose 3-dimensional Ferrers diagram fits in a 4\( \times \)4\( \times \)4 box. We encode this plane
partition by labeling the vertices of the Hasse diagram of $\Lambda_{Gr(4,8)}$ with their heights, and add $i$ to the label of each vertex of height $i$ to obtain an increasing tableau of shape $\Lambda_{Gr(4,8)}$ (the rectangle). The embedding of $\Lambda_{Gr(4,8)}$ inside $\Lambda_{OG(8,16)}$ has the effect of adding two empty half-diamonds of vertices—one to the top of the labeled Hasse diagram, and one to the bottom. To conserve space, we have only drawn the lower part of this embedding, since our operations won’t interact with the top half-diamond.

Our bijection sequentially performs $K$-theoretic jeu-de-taquin slides into the lower vacant half-diamond—these slides behave just like their ordinary jeu-de-taquin counterparts, except that when there are ties, “everybody wins” (see Section 6.2.1 for more details). For $i < j$, this rule is determined by the local pictures

Unlike in the classical jeu-de-taquin theory, the order of these slides matters; as illustrated below, we perform slides row by row into the half-diamond, starting with the highest row.
In fact—no matter the starting increasing tableau of shape $\Lambda_{\text{Gr}(4,8)}$—after applying this process, the labeled vertices are always the dual of the shape $\Phi^+_B(4,8)$ (the shifted trapezoid). We obtain the desired bijection by subtracting $i$ from the labels of each vertex of height $i$, and interpreting the resulting labeling as a plane partition in $\mathbb{P}^i(\Phi^+_B(4,8))$.

1.5. Cohomology. It is natural to ask what happens to our theory in the context of ordinary cohomological Schubert calculus. To address this, we define a linear extension of a poset $P$ with $n$ elements to be a strictly order-preserving bijection $T : P \to [n]$, where $[n] := \{1, 2, \ldots, n\}$. That is, if $p > q \in P$ then $T(p) > T(q)$. We call linear extensions of a general poset $P$ standard tableaux, and we write $\text{ST}(P)$ for the set of all linear extensions of $P$.

Just as increasing tableaux govern the structure coefficients of $K$-theoretic Schubert calculus of minuscule varieties, standard tableaux are used to compute the Schubert structure coefficients in the ordinary cohomology ring $\mathbb{P}^i(P)$. We note that every standard tableau is also an increasing tableau, reflecting the fact that the $K$-theoretic Schubert calculus is a richer theory (but see Theorem 5.2).

The order polynomial of $P$ encodes the number of its standard tableaux. As in [Sta72, Proposition 13.1], the leading coefficient of the order polynomial $|\mathbb{P}^i(P)|$ of $P$ is $\frac{n!}{n^n} |\text{ST}(P)|$. Hence, equating leading coefficients, two doppelgängers $P$ and $Q$ must have the same number of standard tableaux. In fact, our bijections in Theorem 1.3 restrict from $K$-theory to ordinary cohomology, giving bijections between the standard tableaux for the doppelgängers of Figure 1.

Theorem 1.7. Fix $(X,Y) \in \{(\text{Gr}(k,n), B_{k,n}), (\text{OG}(6,12), H_3), (\mathbb{Q}^{2n}, I_2(2n))\}$.

Then under the inclusion $\text{ST}(P) \subseteq \text{IT}^{[n]}(P)$, the bijections of Theorem 1.3 restrict to bijections

$$\text{ST}(\Lambda_X) \simeq \text{ST}(\Phi^+_Y).$$

Remark 1.8. In his study of dual equivalence [Hai92], M. Haiman gave an elegant jeu-de-taquin bijection called rectification for the identity

$$|\text{ST}(\Lambda_{\text{Gr}(k,n)})| = |\text{ST}(\Phi^+_B(4,8))|.$$  

Our bijection of Theorem 1.3 simultaneously generalizes M. Haiman’s bijection and provides the sought-after bijective proof of R. Proctor’s result for plane partitions. In Example 1.6, we have boxed the standard tableaux that correspond to the restriction of our bijection to M. Haiman’s result.
2. Philosophy and Outline

The general idea of our approach may be summarized as follows:

Given a ring with a basis indexed by combinatorial objects and a combinatorial rule for structure coefficients, multiplicity-free products in the ring are equivalent to bijections.

In this section, we give a short example of this philosophy by sketching the argument of a parallel result due to R. Stanley [Sta86]. The organization of our paper then mirrors this example.

**Theorem 2.1** (R. Stanley [Sta86, Section 3]). *The number of self-complementary plane partitions inside a \((2a) \times (2b) \times (2c)\) box is equal to the number of pairs of plane partitions, each fitting inside an \(a \times b \times c\) box.*

2.1. A Ring. Recall that the ring of symmetric polynomials in \(n\) variables consists of those polynomials invariant under the natural action of the symmetric group \(S_n\):

\[ \text{Sym}_n := \{ f \in \mathbb{Q}[x_1, \ldots, x_n] : w \cdot f = f \text{ for all } w \in S_n \}, \]

where \(w \cdot x_i = x_{w(i)}\).

We fix some notation. An integer partition is a tuple \(\lambda = (\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n > 0)\) with \(\lambda_i \in \mathbb{Z}_{>0}\). We say that \(\lambda\) has \(n\) parts. The representation theory of the symmetric and general linear groups assigns a poset to \(\lambda\) as follows. The Ferrers shape of \(\lambda\) is drawn in the quarter plane \(Z_{>0} \times Z_{\leq 0}\) as \(k\) left-justified rows of axis-aligned unit squares (boxes) of lengths \(\lambda_i\). We define a partial order on any collection of boxes in the quarter plane by letting a box be less than or equal to any box weakly below it and weakly to its right. When the collection of boxes defines a connected subset of the quarter plane, the Hasse diagram is obtained by vertically reflecting, then rotating the plane by \(45^\circ\) counterclockwise, drawing edges between boxes that share an edge, and replacing all boxes by vertices.

For \(\lambda\) a partition with at most \(n\) parts, let \(\text{SSYT}_n(\lambda)\) be the set of semistandard tableaux of shape \(\lambda\)—fillings of the Ferrers shape of \(\lambda\) with numbers in \([n]\) that weakly increase across rows, and strictly increase down columns (see the top right tableau in Figure 4 for an example). The ring \(\text{Sym}_n\) has a linear basis of Schur polynomials \(\{s_\lambda : \lambda\text{ has at most }n\text{ parts}\}\), where

\[ s_\lambda := \sum_{T \in \text{SSYT}_n(\lambda)} \prod_{i=1}^n x_i^{\text{number of times } i \text{ appears in } T}. \]

2.2. A Multiplicity-Free Product. R. Stanley’s argument hinges on the following multiplicity-free identity in \(\text{Sym}_{b+c}\), expressing the square of a Schur polynomial indexed by the rectangular partition \((a^b) := (a, a, \ldots, a)\) in the Schur basis:

\[ s_{(a^b)}^2 = \sum_{\gamma} s_\gamma, \]

where \(\gamma\) ranges over the set of partitions

\[ \left\{ (a + \delta_1, \ldots, a + \delta_r, a - \delta_r, \ldots, a - \delta_1) : \delta = (\delta_1, \ldots, \delta_r) \subseteq (a^b) \right\}. \]

This expansion may be proven using a variant of the Littlewood-Richardson rule—more generally, products of two Schur polynomials indexed by different rectangular partitions are multiplicity free.
Example 2.2. For $a = b = 2$, we have the $\binom{a+b}{a} = \binom{4}{2} = 6$-term expansion

$$s_2^2 = s_{21}^2 + s_{14} + s_{20}^2 + s_{03} + s_{02}^2 + s_{01}$$

Theorem 2.1 follows from Equation (2.1) as follows. The terms in the product on the left-hand side of Equation (2.1) are indexed by pairs of rectangular semistandard tableaux with entries in $[b + c]$ (top left of Figure 4). By subtracting $i$ from the $i$th row, we produce a pair of plane partitions, each fitting inside an $a \times b \times c$ box, from this pair of semistandard tableaux (bottom left of Figure 4).

We need to do slightly more work to identify the right-hand side of Equation (2.1). For each term from the right-hand side, we again have a semistandard tableau (top right of Figure 4), generally of nonrectangular shape. As before, we subtract $i$ from the $i$th row of the tableau to produce a plane partition. Now observe that the partitions $\lambda$ occurring in the sum on the right-hand side of Equation (2.1) are exactly of the form required so that $\lambda$ and its rotation by $180^\circ$ may be placed together to form a rectangular partition of shape $(2a) \times (2b)$. The proof of Theorem 2.1 is completed by noting that the filling of this rotation is specified by the self-complementarity condition (bottom right of Figure 4).

2.3. A Bijection from a Rule for Structure Coefficients. As sketched at the end of [Sta86, Section 3], Theorem 2.1 can be realized with a simple bijection. Semistandard tableaux (unlike plane partitions) come with a theory of jeu-de-taquin. By a standard combinatorial version of the Littlewood-Richardson rule (see [Ful97, Chapter 5]), placing the initial pair of semistandard tableaux “kitty-corner” from each other and applying jeu-de-taquin until arriving at a north-west-justified (“straight”) shape gives a bijection from the pairs of tableaux representing the left-hand side of Equation (2.1) to the semistandard tableaux representing the terms of the right-hand side.

![Figure 4](image-url)

**Figure 4.** An illustration of the bijective proof of Theorem 2.1 between pairs of plane partitions in a $3 \times 4 \times 3$ box and self-complementary plane partitions in a $6 \times 8 \times 6$ box.

2.4. Outline of the Paper. In summary, our philosophy is that a multiplicity-free identity in a ring with a combinatorial rule for structure coefficients is equivalent to a bijection. In this paper, we apply this philosophy using the objects and tools of
minuscule $K$-theoretic Schubert calculus. To obtain the bijections of Theorem 1.3, we therefore need:

- combinatorial objects (Section 4);
- rings with bases indexed by those objects (Section 5);
- combinatorial rules to compute structure coefficients in those rings (Section 6); which lead to
- bijections (Theorem 7.2), and their equivalent
- multiplicity-free identities (Theorem 7.1); which allow us to
- identify interesting special cases (Sections 8 to 10).

The remainder of the paper is structured as follows. In Section 3, we review required background and fix notation for posets, root systems, reflection groups, and flag varieties. In Section 4, we describe minuscule (co)weights and their associated posets. In Section 5, we recall the basic notions of (cohomological and $K$-theoretic) Schubert calculus, building to the powerful combinatorial toolkit of Section 6.

In Section 7, we state and prove our main theorem (Theorem 7.2), which provides a bijective framework for doppelgängers. We then turn to the task of applying Theorem 7.2 to prove Theorem 1.3. We recall the coincidental types and their root posets in Section 8, and Section 9 is then devoted to embedding the posets in the first two columns of Figure 2 inside ambient minuscule posets. Finally, we specialize Theorem 7.2 in Section 10 to conclude Theorem 1.3.

In Section 11, we outline some related open problems.

3. Background

In this section, we fix notation and review background on posets, root systems, real reflection groups, and flag varieties. We refer the reader to [Hil82, Hum92, Kan01] for more comprehensive treatments; we follow the notation of [Hum92].

3.1. Posets. An order ideal of a poset $P$ is a subset $w \subseteq P$ such that $y \succ x$ and $y \in w$ together imply $x \in w$. We call an order ideal $w$ of $P$ a straight shape, and the difference of two straight shapes $w \subseteq v$ a skew shape $v/w$. Note that $v$ is the special case of a skew shape for $w = \emptyset$. Similarly, an order filter is a subset of $P$ whose complement is an order ideal, and we call an order filter an anti-straight shape. As subposets of $P$, order ideals and filters inherit a partial order. We write $J(P)$ for the set of all order ideals of a poset $P$, noting that $J(P)$ is itself a poset under inclusion of order ideals. Observe that there is a natural correspondence $J(P) \simeq P^{[1]}(P)$ and, more generally,

$$J(P \times \ell) \simeq P^{[\ell]}(P).$$

A lattice $L$ is a poset such that any two $w, u \in L$ have both a least upper bound $w \lor u$ and a greatest lower bound $w \land u$. An element $v$ in a lattice $L$ is *join-irreducible* if $v = w \lor u$ implies $v \in \{w, u\}$. Associated to a lattice $L$ is its subposet $L_{ji}$ of join-irreducibles under the restriction of the partial order on $L$. A lattice $L$ is a *distributive lattice* if the binary operations $\lor$ and $\land$ distribute over each other. The *fundamental theorem of distributive lattices* states that for any finite distributive lattice $L$, $J(L_{ji}) \cong L$ [Bir37].

Remark 3.1. Recall from Section 2.1 that an integer partition defines a Ferrers shape. Similarly, a strict integer partition $\lambda = (\lambda_1 > \lambda_2 > \cdots > \lambda_k > 0)$ defines a *shifted Ferrers shape* by indenting the $i$th row $i$ steps to the right. When working with Ferrers and shifted Ferrers shapes, we often find it convenient to switch to the English convention on tableau orientation. That is, we vertically reflect and then rotate our tableaux $135^\circ$ clockwise so “gravity” now points north-west. We
3.2. Root Systems. Let $V$ be a real Euclidean space of rank $n$ equipped with a nondegenerate symmetric inner product $(\cdot, \cdot)$. Let $\Phi \subset V$ be an irreducible (finite) root system; we do not assume $\Phi$ is crystallographic. Fix a choice of positive roots $\Phi^+$ and of simple roots $\Delta := \{\alpha_1, \alpha_2, \ldots, \alpha_n\}$. When we wish to differentiate types, we will write $\Phi = \Phi(X_n)$ for the root system of type $X_n$ (and similarly for other objects). For a root $\alpha$, let $\alpha^\vee := 2\frac{\alpha}{(\alpha, \alpha)}$ be the corresponding coroot and let $\Phi^\vee = \{\alpha^\vee : \alpha \in \Phi\}$ be the dual root system.

The root system $\Phi$ is crystallographic if $\langle \alpha, \beta^\vee \rangle \in \mathbb{Z}$ for all $\alpha, \beta \in \Phi$. For $\Phi$ crystallographic, we let $Q := \mathbb{Z}\Phi$ be the root lattice, $Q^\vee := \mathbb{Z}\Phi^\vee$ the coroot lattice, and define the weight lattice (whose elements are weights)

$$\Lambda := \{\omega \in V : \langle \omega, \alpha^\vee \rangle \in \mathbb{Z} \text{ for all } \alpha \in \Delta\}$$

and the coweight lattice (whose elements are coweights)

$$\Lambda^\vee := \{\omega \in V : \langle \omega, \alpha \rangle \in \mathbb{Z} \text{ for all } \alpha \in \Delta\}.$$ 

As abelian groups, $\Lambda$ contains $Q$ as a subgroup and the finite number $f := |\Lambda/Q|$ is called the index of connection. For each simple root $\alpha_i \in \Delta$, there is a corresponding fundamental weight $\omega_i \in \Lambda$ defined by $\langle \omega_i, \alpha_j^\vee \rangle = \delta_{ij}$, where $\delta_{ij}$ is the Kronecker delta. The fundamental coweights are defined analogously. A weight $\omega$ is dominant if $\langle \omega, \alpha_i^\vee \rangle \geq 0$ for all $\alpha_i \in \Delta$. Each fundamental weight is dominant, and a weight is dominant exactly if it is a nonnegative linear combination of fundamental weights.

The dominance order is the partial order on $\Lambda$ given by

$$\lambda \prec \omega \text{ if and only if } \omega - \lambda \text{ is a nonnegative sum of simple roots.}$$

The positive root poset is the restriction of dominance order to the positive roots $\Phi^+$. The height of a positive root $\alpha = \sum_{i=1}^n a_i \alpha_i$ is the positive integer $\text{ht}(\alpha) = \sum_{i=1}^n a_i$. Abusing notation, we write $\Phi^+$ for the positive root poset, and we note that $\Phi^+$ has a unique maximal element $\tilde{\alpha}$ called the highest root.

3.3. Reflection Groups.

3.3.1. Classification. For $\alpha \in \Phi^+$, we define the reflection $s_\alpha : V \rightarrow V$ by

$$s_\alpha(v) := v - (v, \alpha)\alpha^\vee$$

for $v \in V$. The (real) reflection group of $\Phi$ is the group $W = \langle s_\alpha : \alpha \in \Phi^+ \rangle \subset O(V)$ generated by these reflections. Using our choice of simple roots $\Delta = \{\alpha_i\}_{i=1}^n$, $W$ is generated by the simple reflections $S = \{s_{\alpha_i} : \alpha_i \in \Delta\}$. We abbreviate $s_i := s_{\alpha_i}$.

The simple reflections give $W$ a distinguished Coxeter presentation

$$W = \langle s_1, s_2, \ldots, s_n : s_i^2 = (s_is_j)^{m_{ij}} = e \rangle,$$

where $e$ is the identity element of $W$ and $m_{ij} = m_{ji}$ are certain positive integers. The pair $(W, S)$ of the finite reflection group and a choice of simple reflections is a finite Coxeter system. The relations $(s_is_j)^2 = e$ are called commutation relations, while higher-order relations $(s_is_j)^{m_{ij}}$ for $m_{ij} > 2$ are called braid relations. The Coxeter presentation of $W$ is encoded by its Coxeter-Dynkin diagram, the edge-labeled complete graph with vertex set $S$, where the edge from $s_i$ to $s_j$ is labeled by $m_{ij}$. By a standard convention, we omit the edges with label 2 (corresponding to commutations of simple reflections) and omit labels equal to 3. We also use a double edge to denote the label 4 and a triple edge for the label 6, with an arrow on each such edge pointing toward the shorter simple root. Figure 5 displays the Coxeter-Dynkin diagrams for the finite irreducible reflection groups (for now, ignore the vertices colored black).
With some low-dimensional redundancy, finite irreducible real reflection groups are classified as the crystallographic types \(A_n, B_n, D_n, E_6, E_7, E_8, F_4,\) and \(G_2\) (which come from crystallographic root systems), and the noncrystallographic types \(H_3, H_4,\) and \(I_2(m)\) (for \(m \neq 1, 2, 3, 4, 6\)). We shall refer to these symbols as \textit{Coxeter-Cartan types}.

Each finite crystallographic real reflection group \(W\) has an affine extension \(\tilde{W} = W \ltimes Q^\vee\) obtained by adding a new “affine” simple reflection \(s_0\) across an affine hyperplane perpendicular to \(\tilde{\alpha}\). That is,

\[
\tilde{W} = \langle s_0, s_1, \ldots, s_n \rangle,
\]

where \(s_0 : V \to V\) is defined by

\[
s_0(v) := v - ((v, \tilde{\alpha}) - 1) \tilde{\alpha}^\vee.
\]

The affine roots correspond to the vertices colored black in Figure 5.

**Figure 5.** In crystallographic type, the roots \(\alpha_i\) marked in gray have a corresponding cominuscule fundamental weight \(\omega_i\); the affine simple root is marked in black. For \(H_3\) and \(I_2(m)\), the roots marked in gray correspond to maximal parabolic quotients \(W^{(i)}\) whose longest element is fully commutative.

3.3.2. \textit{Weak Order.} For \(w \in W\), we write \(\text{len}(w)\) for the \textit{length} of \(w\), i.e. the least \(j\) such that \(w\) can be written as \(w = s_{i_1}s_{i_2}\cdots s_{i_j}\) for some sequence of simple reflections and define

\[
\text{Red}(w) := \{(s_{i_1}, s_{i_2}, \ldots, s_{i_j}) : w = s_{i_1}s_{i_2}\cdots s_{i_j} \text{ and } j = \text{len}(w)\}
\]

for its set of \textit{reduced words}. There is the structure of a graph on \(\text{Red}(w)\) by drawing edges between two reduced words when they differ by a commutation or braid relation; by Matsumoto’s theorem, this graph is connected.
We define the inversion set of \( w \in W \) by
\[
\text{inv}(w) = (-w(\Phi^+)) \cap \Phi^+ = \{ \alpha_{i_1}, s_{i_1}(\alpha_{i_2}), \ldots, s_{i_1}s_{i_2} \cdots s_{i_{j-1}}(\alpha_{i_j}) \},
\]
where \( s_{i_1}s_{i_2} \cdots s_{i_j} \) is any reduced word for \( w \). Clearly, one has \( |w| = \text{len}(w) \) for all \( w \in W \). We will often think of the inversion set of \( w \) as a subposet of the positive root poset.

The Demazure product on \( W \) is defined by setting
\[
s_i \cdot w := \begin{cases} s_i w & \text{if } \text{len}(s_i w) > \text{len}(w) \\ w & \text{otherwise} \end{cases}
\]
and then extending to products of arbitrary elements. (The Demazure product is well-defined and associative—it corresponds to the product in the 0-Hecke algebra, and yields a monoid structure on \( W \).

The weak order is the partial order on \( W \) defined by \( w \leq v \) if and only if \( w \subseteq v \).

The group \( W \) has a unique longest element \( w_0 \), which is maximal in the weak order.

3.3.3. Parabolic Subgroups and Quotients. A parabolic subgroup \( W_J \subset W \) is a group generated by a subset \( J \subset S \) of the simple reflections, with (possibly reducible) subroot system \( \Phi_J \subseteq \Phi \). A maximal parabolic subgroup is one for which \( J = S \setminus \{ s_i \} \)—we shall denote such a subgroup by \( W(\iota) \) and its root system by \( \Phi(\iota) \). The set \( W^J := W/W_J \) is a parabolic quotient; we identify \( W^J \) with its minimal-length coset representatives and write \( W^{(\iota)} := W/W(\iota) \).

Any \( w \in W \) can be written as \( w = w_J w^J \) with \( w_J \in W_J \) and \( w^J \in W^J \). We write \( w_\alpha(J) \) for the unique longest element of \( W_J \). Each parabolic quotient \( W^J \) also has a longest element \( w^J_0 = w_\omega w_\omega(J) \), and \( W^J \) consists of the elements in the closed interval \( [\varepsilon, w^J_0] \) of \( W \). As an interval in the weak order, the parabolic quotient \( W^J \) therefore inherits the partial ordering from \( W \). The map
\[
: W^J \to W^J \\
w \mapsto \hat{w} = w_\omega w_\omega(J)
\]
is an antiautomorphism of the poset \( W^J \).

3.4. Flag Varieties. Let \( G \) be a semisimple complex Lie group. Inside \( G \), fix a Borel subgroup \( B \), an opposite Borel subgroup \( B_- \) and a maximal torus \( T := B \cap B_- \). For example, if \( G = \text{SL}(n) \), we may choose \( B \) to be the subgroup of upper triangular matrices in \( \text{SL}(n) \) and \( B_- \) to be the lower triangular matrices in \( \text{SL}(n) \), whence \( T := B \cap B_- \) would be uniquely determined as the diagonal matrices in \( \text{SL}(n) \).

One recovers the data of Section 3.2 in the following way. The Weyl group of \( G \) is \( W := N(T)/T \), where \( N(T) \) is the normalizer of \( T \) in \( G \). Consider the complex Lie algebra \( \mathfrak{g} \) of \( G \). The Cartan subalgebra \( \mathfrak{t} \) is the Lie algebra of the maximal torus \( T \). The adjoint action of \( \mathfrak{t} \) on \( \mathfrak{g} \) can be simultaneously diagonalized, so \( \mathfrak{g} \) decomposes into a direct sum of weight spaces as
\[
\mathfrak{g} = \bigoplus_{\omega \in \mathfrak{t}^*} \mathfrak{g}_\omega,
\]
where the direct sum is over linear functionals on \( \mathfrak{t} \). In fact, \( \mathfrak{g}_0 = \mathfrak{t} \), and this decomposition can be rewritten as
\[
\mathfrak{g} = \mathfrak{t} \oplus \bigoplus_{\alpha \in \Phi} \mathfrak{g}_\alpha,
\]
where \( \Phi \) is a finite set of nonzero vectors in the dual space \( \mathfrak{t}^* \) and each \( \mathfrak{g}_\alpha \) is a one-dimensional subspace of \( \mathfrak{g} \). It turns out that \( \Phi \) is a crystallographic root system. Let \( \mathfrak{b} \) and \( \mathfrak{b}_- \) be the Lie algebras of the Borel subgroup \( B \) and opposite Borel subgroup
B−, respectively. For each α ∈ Φ, either \( g_α \subseteq b \) or \( g_α \subseteq b − \). We obtain a choice of positive roots \( Φ^+ \) from our choice of Borel subgroup by

\[
Φ^+ = \{ α ∈ Φ : g_α \subseteq b \}.
\]

The decomposition of \( Φ \) into positive and negative roots uniquely determines a set of simple roots \( Δ \).

Moreover, the Lie group \( G \) decomposes as the disjoint union (the Bruhat decomposition)

\[
G = \bigsqcup_{w ∈ W} B−wB.
\]

More generally, for \( P ⊇ B \) a parabolic subgroup of \( G \), we write \( W_P = W/W_P \) for the corresponding parabolic quotient and subgroup of \( W \). Then

\[
G = \bigsqcup_{w ∈ W_P} B−wP
\]

and the generalized flag variety \( G/P \) has the Schubert cell decomposition

\[
G/P = \bigsqcup_{w ∈ W_P} B−wP/P.
\]

With these conventions, the Schubert cell \( B−wP/P \) has codimension \( \text{len}(w) \).

4. Minuscule Weights and Posets

Let \( Φ \) be a crystallographic root system and \( Λ \) its weight lattice. In this section, we recall the definition of a minuscule weight \( ω ∈ Λ \). For each such minuscule weight \( ω \), we then define the minuscule poset associated to \( ω \) as a subset of the poset \( Φ^+ \) of positive roots. After recalling some combinatorics associated to minuscule posets in Sections 5 and 6, we will use these posets to formulate our bijective framework for doppelgängers in Section 7. For full background, we refer the reader to Bourbaki [Bou75, Chapitre VIII, §7.3], H. Hiller’s text [Hil82, Chapter V, §2], and R. Green’s recent book [Gre13]. The combinatorial aspects of minuscule weights that we recall here have been thoroughly studied, exploited, and extended by R. Stanley, R. Proctor, and J. Stembridge [Sta80, Pro84, Ste96, Ste98, Ste01a], among others. For discussion of the geometric aspects, see the book of S. Billey and V. Lakshmibai [BL00].

4.1. Minuscule Weights.

**Definition 4.1.** A nonzero dominant weight \( ω ∈ Λ \) is called minuscule if \( ⟨ω, α^∨⟩ \in \{-1, 0, 1\} \) for all \( α ∈ Φ \).

A minuscule weight for the dual root system \( Φ^∨ \) is called a minuscule coweight; the corresponding weight of the original root system is called cominuscule. The vertices of Dynkin diagrams whose corresponding coweight is minuscule are marked in gray in Figure 5.

**Theorem 4.2.** For \( ω \) a dominant coweight in crystallographic Coxeter-Cartan type, the following are equivalent:

1. \( ω \) is minuscule—\( that \) is, \( ω \neq 0 \) and \( ⟨ω, α⟩ \in \{-1, 0, 1\} \) for all \( α ∈ Φ \);
2. \( ω = ω_i \) is a fundamental coweight, and \( c_i = 1 \) in the expansion \( \tilde{α} = \sum_{j=1}^n c_jα_j \) of the highest root in the simple root basis;
3. \( ω = ω_i \) is a fundamental coweight, and there is an automorphism of the affine Dynkin diagram sending \( α_0 \) to \( α_i \);
4. \( ω \) is a nonzero minimal representative of \( Λ^∨/Q^∨ \) in the dominance order.
4.2. Minuscule Posets. The subgroup of the reflection group \( W \) that stabilizes a fundamental weight \( \omega_i \) is the maximal parabolic subgroup \( W_{(i)} \). Let \( P \) be the corresponding maximal parabolic subgroup of \( G \). The minuscule poset for a minuscule coweight \( \omega_i \) is the order filter in the root poset \( \Phi^+ \) generated by the corresponding simple root \( \alpha_i \):

\[
\Lambda_{G/P} := \left\{ \alpha \in \Phi^+ : \text{if } \alpha = \sum_{j=1}^{n} c_j \alpha_j, \text{ then } c_i \neq 0 \right\} = \Phi^+ \setminus \Phi^+_{(i)}.
\]

By the orbit-stabilizer theorem, the minimal coset representatives \( w \) of the parabolic quotient \( W_{(i)} := W/W_{(i)} \) are in bijection with the weights in the orbit \( \{ w(\omega_i) : w \in W \} \) of \( \omega_i \). We now follow J. Stembridge and R. Proctor to give an explicit combinatorial description of these quotients in the case \( \omega_i \) is a minuscule weight.

Fix \( w \in W \) with \( \text{len}(w) = j \) and let \( w = (s_{k_1}, s_{k_2}, \ldots, s_{k_j}) \) be a reduced word for \( w \). Define a partial order \( \prec_w \) on \([j]\) by the transitive closure of the relations

\[
(4.2) \quad i \prec_w j \text{ if } i < j \text{ and } s_{k_i} s_{k_j} \neq s_{k_j} s_{k_i}.
\]

This partial ordering defines an ordering on \([j]\) called a heap [Vie86, Ste96], and hence gives an ordering of the roots in the inversion set \( w \) of \( w \).

A fully commutative element \( w \in W \) is one whose graph \( \text{Red}(w) \) of reduced words is connected using only commutations (that is, without braid relations). For any two reduced words of a fully commutative \( w \), it is then not difficult to see that the two induced partial orderings on \( w \) are isomorphic. Therefore, when \( w \in W \) is fully commutative, we may unambiguously refer to the heap \( w \) of \( w \).

![Figure 6](image.png)

**Figure 6.** For \( W = W(A_3) \), the minuscule weight \( \omega_2 \) is fixed by the parabolic subgroup \( W_{(2)} \). The corresponding quotient \( W^{(2)} \) has a fully commutative longest element \( w^{(2)}_0 = s_2 s_1 s_3 s_2 \), whose heap is \( w^{(2)}_0 = [2] \times [2] \simeq \Lambda_{G(2,4)} \).

**Theorem 4.3** ([Ste96, Proposition 2.2 and Lemma 3.1]). For \( w \) fully commutative, there is a bijection between standard tableaux of the heap of \( w \) and reduced words for \( w \):

\[
\text{ST}(w) \simeq \text{Red}(w).
\]

This induces an order isomorphism between the distributive lattice of order ideals of the heap and the weak-order interval \([e, w]\):

\[
J(w) \simeq [e, w].
\]

In [Ste96], J. Stembridge classified all maximal parabolic quotients whose longest element \( w_0^{(6)} \) is fully commutative. This classification is summarized in Figure 5.
When \( W \) is a Weyl group, this classification essentially coincides with the classification of minuscule representations of the corresponding Lie algebra.\(^2\) By Theorem 4.3 and J. Stembridge’s classification, when \( \omega_i \) is minuscule the inversion sets of the elements in \( W^{(i)} \) are order ideals in the heap for the longest element \( w^{(i)}_0 \) of \( W^{(i)} \). This heap may now be simply described by Equation (4.1) as the order filter in \( \Phi^+ \) generated by \( \alpha_i \).

This discussion is summarized by the theorem below.

**Theorem 4.4** (R. Proctor [Pro84]). When \( \omega \) is a minuscule coweight, there is an order isomorphism

\[
W^P \simeq J(\Lambda_{G/P})
\]

\( u \mapsto u \),

where \( W^P := \{ w \in W : w(\omega) = \omega \} \) and \( P \) is the corresponding maximal parabolic subgroup of \( G \).

In particular, for \( \omega \) minuscule, the weak order on \( W^P \) is a distributive lattice. When \( \omega \) is a (co)minuscule weight, we shall also use the term (co)minuscule to describe the corresponding flag variety \( G/P \) and poset \( \Lambda_{G/P} \).

### 4.3. Explicit Constructions

We explicitly identify the minuscule posets from Figure 1 by giving reduced words for \( w^{(i)}_0 \). The corresponding posets can then be built as heaps using Equation (4.2).

#### 4.3.1. \((A_{n-1}, k)\): the Grassmannian \( Gr(k, n) \). In type \( A_{n-1} \), any fundamental weight \( \omega_k \) is minuscule. For \( W = W(A_{n-1}) \), the longest element \( w^{(k)}_0 \) of \( W^{(k)} \) has reduced word

\[
w^{(k)}_0 = \prod_{j=1}^{n-k} \prod_{i=k-j+1}^{n-j} s_i.
\]

The poset \( \Lambda_{Gr(k,n)} \) is commonly described as a \([k] \times [n-k] \) rectangle, represented as the partition \((n-k)^k = (n-k, n-k-1, \ldots, n-k)\). Thus, as in Remark 3.1, an order ideal in \( \Lambda_{Gr(k,n)} \) (for any \( k, n \)) may be drawn as a Ferrers shape. The corresponding minuscule variety is a Grassmannian \( Gr(k,n) \), a parameter space for \( k \)-dimensional linear subspaces of \( \mathbb{C}^n \).

#### 4.3.2. \((C_n, 1)\): the Lagrangian Grassmanian \( LG(n, 2n) \). In type \( C_n \), \( \omega_1 \) is a cominuscule weight. For \( W = W(C_n) \), the longest element \( w^{(1)}_2 \) of \( W^{(1)} \) has reduced word

\[
w^{(1)}_2 = \prod_{i=1}^{n} \prod_{j=1}^{n-i+1} s_j,
\]

so that—when drawn as a shifted Ferrers shape as in Remark 3.1—\( \Lambda_{LG(n,2n)} \) is a shifted staircase of order \( n \). We write this as the shifted partition \((n, n-1, \ldots, 1)\). The corresponding cominuscule variety \( LG(n, 2n) \) is a Lagrangian Grassmannian. It can be realized as the subvariety of the type \( A \) Grassmannian \( Gr(n, 2n) \) consisting of those points corresponding to the \( n \)-dimensional linear subspaces of \( \mathbb{C}^{2n} \) that are isotropic with respect to a fixed nondegenerate symplectic form.

---

\(^2\)The Weyl group is not sensitive to the difference between long and short roots, and so confuses types \( B \) and \( C \).
4.3.3. \((D_n, 1)\) and \((D_n, 2)\): the Even Orthogonal Grassmanian \(\text{OG}(n, 2n)\). In type \(D_n\), \(\omega_1\) and \(\omega_2\) are minuscule weights with isomorphic minuscule posets \(\Lambda_{\text{OG}(n, 2n)}\).

For \(W = W(D_n)\), write \(s_{1,2}(j) = \begin{cases} s_1 & \text{if } j \text{ is odd} \\ s_2 & \text{if } j \text{ is even} \end{cases}\). The longest elements of \(W^{(i)}\) for \(i \in \{1, 2\}\) have reduced words

\[
w^{(1)}_s = \prod_{j=1}^{\lfloor n/2 \rfloor} \begin{pmatrix} n \choose j \) s_{1,2}(j) \prod_{k=3}^{n-j+1} s_k \end{pmatrix} \\
w^{(2)}_s = \prod_{j=1}^{\lfloor n/2 \rfloor} \begin{pmatrix} n \choose j + 1 \) s_{1,2}(j + 1) \prod_{k=3}^{n-j+1} s_k \end{pmatrix}
\]

When drawn as a shifted Ferrers shape, the poset \(\Lambda_{\text{OG}(n, 2n)}\) is a shifted staircase of order \(n - 1\). The even orthogonal Grassmanian \(\text{OG}(n, 2n)\) is the minuscule subvariety of \(\text{Gr}(n, 2n)\) parametrizing those \(n\)-dimensional linear subspaces of \(\mathbb{C}^{2n}\) that are isotropic with respect to a fixed nondegenerate symmetric bilinear form.

4.3.4. \((D_n, n)\): the Even Dimensional Quadric \(\mathbb{Q}^{2n-2}\). Again in type \(D_n\), the weight \(\omega_n\) is also minuscule but with poset \(\Lambda_{\mathbb{Q}^{2n-2}}\). The corresponding longest element of \(W^{(n)}\) has reduced word

\[
w^{(n)}_s = \left( \prod_{j=3}^{n} s_j \right)^{-1} (s_1 s_2) \left( \prod_{j=3}^{n} s_j \right).
\]

The poset \(\Lambda_{\mathbb{Q}^{2n-2}}\) can be compactly described as either the iterated distributive lattice of order ideals \(\mathcal{J}^{n-3}(\{2\} \times \{2\})\), or as the ordinal sum of a chain of length \(n - 2\), an antichain of size 2, and a chain of length \(n - 2\):

\[
\Lambda_{\mathbb{Q}^{2n-2}} := [n - 2] \oplus ([1] \cup [1]) \oplus [n - 2].
\]

The corresponding minuscule variety is a quadric hypersurface \(\mathbb{Q}^{2n-2}\).

4.3.5. \((E_6, \omega_1)\) and \((E_6, \omega_6)\): the Cayley plane. In type \(E_6\), \(\omega_1\) and \(\omega_6\) are minuscule weights with isomorphic minuscule posets \(\Lambda_{\mathbb{G}^{2}}\). For \(W = W(E_6)\), the longest elements of \(W^{(i)}\) for \(i \in \{1, 6\}\) have reduced words

\[
w^{(1)}_s = s_1 s_3 s_4 s_5 s_6 s_7 \cdots s_{18} s_{25} s_{32} s_{39} s_{46} s_{53} s_{60};
\]

\[
w^{(6)}_s = s_6 s_5 s_4 s_3 s_2 s_1 s_8 s_7 s_6 s_5 s_4 s_3 s_2 s_1 s_8 s_7 s_6 s_5 s_4 s_3 s_2 s_1.
\]

The corresponding minuscule variety is the Cayley plane \(\mathbb{G} \mathbb{P}^2\), the projective plane over the complexification of the octonions. This space was first constructed by R. Moufang [Mou33]. For further discussion of the Cayley plane, see the thorough exposition of J. Baez [Bae01].

4.3.6. \((E_7, \omega_1)\): the Freudenthal variety \(\mathbb{G}_2(\mathbb{O}^3, \mathbb{O}^6)\). In type \(E_7\), only \(\omega_1\) is a minuscule weight. For \(W = W(E_7)\), a reduced word for the longest element of \(W^{(1)}\) is

\[
w^{(1)}_s = s_1 s_3 s_4 s_5 s_6 s_7 s_8 s_9 s_{10} s_{11} s_{12} s_{13} s_{14} s_{15} s_{16} s_{17} s_{18} s_{19} s_{20} s_{21} s_{22} s_{23} s_{24} s_{25} s_{26} s_{27} s_{28} s_{29} s_{30} s_{31}.
\]

The poset \(\Lambda_{\mathbb{G}_2(\mathbb{O}^3, \mathbb{O}^6)}\) is the second poset from the left in Figure 3. We refer to the corresponding minuscule variety as the Freudenthal variety. This space parametrizes certain copies of \(\mathbb{O}^3\) in \(\mathbb{O}^6\), where \(\mathbb{O}\) denotes the complexification of the octonions; for details, see the work of J. Tits [Tit55, §E.5].
5. Schubert Calculus

We now turn to the algebro-geometric context for minuscule posets. This section sets up the rings necessary to state Theorem 7.1, which establishes an equivalence between products in these rings and certain bijections. The equivalence will follow from the combinatorics of the structure coefficients for the rings, which we review in Section 6.

5.1. Cohomology. Recall from Section 3.4 that for $P$ a parabolic subgroup of $G$, the generalized flag variety $G/P$ has the Bruhat decomposition

$$G/P = \bigsqcup_{w \in W^P} B_- wP/P.$$ 

For $w \in W^P$, the Schubert variety is the closures $X_w := B_- wP/P$, while the opposite Schubert variety is $X^w := B^- wP/P$. Schubert varieties intersect transversally with opposite Schubert varieties, and the intersection $X^w_w := X_w \cap X^w$ is called a Richardson variety. The Schubert classes $\sigma_w$ are the Poincaré duals of the Schubert varieties. Since the Bruhat decomposition is a cell decomposition, the set $\{\sigma_w\}_{w \in W^P}$ is a $\Z$-linear basis of the cohomology ring $H^*(G/P, \Z)$. As such, any cup product $\sigma_w \cdot \sigma_u$ of basis elements can be expressed in the basis:

$$\sigma_w \cdot \sigma_u = \sum_{v \in W^P} c^v_{w,u} \sigma_v.$$ 

In this setting, $H^*(G/P, \Z)$ is isomorphic to the Chow ring $A^*(G/P)$ of subvarieties up to rational equivalence, where the ring product is given by transverse intersection.

The Borel homomorphism from $H^*(\Gr(k, n))$ to the coinvariant ring identifies Schubert classes with Schur functions, and in this case the $c^v_{w,u}$ are known as the Littlewood-Richardson coefficients [Les47]. This setup therefore generalizes the specific example discussed in Section 2.

For $G/P$ minuscule, H. Thomas and A. Yong gave a uniform combinatorial formula for $c^v_{w,u}$ [TY09a]. Their formula generalizes M.-P. Schützenberger’s well-known rule for $G/P = \Gr(k, n)$. Given a standard tableau $T \in ST(v/w)$, there is a rectification map (whose definition we defer until Section 6.2.2, where it will be given in greater generality) that produces a tableau $\text{rect}(T) \in ST(v')$, for some $v' \in W^P$.

Theorem 5.1 ([TY09a]). For $G/P$ minuscule, the coefficient $c^v_{w,u}$ equals the number of standard tableaux $T \in ST(v/w)$ whose rectification is any fixed standard tableau of shape $u$.

5.2. K-Theory. K-theoretic Schubert calculus turns to the Grothendieck ring $K(G/P)$ of algebraic vector bundles over $G/P$ as a richer variant of the ordinary cohomology ring $H^*(G/P)$. The $K$-theory ring $K(G/P)$ has a $\Z$-linear basis given by the classes of the Schubert varieties’ structure sheaves $\{\mathcal{O}_{X_w}\}_{w \in W^P}$. As before, we have an expansion:

$$[\mathcal{O}_{X_w}] \cdot [\mathcal{O}_{X_u}] = \sum_{v \in W^P} C^v_{w,u} [\mathcal{O}_{X_v}],$$

where now

$$(-1)^{|v|-|w|-|u|} C^v_{w,u} \in \Z_{\geq 0}$$

(as shown in greater generality by M. Brion [Bri02]). These $K$-theoretic structure constants generalize their cohomological counterparts—$C^v_{w,u} = c^v_{w,u}$ whenever $|v| = |w| + |u|$, but when $|v| > |w| + |u|$, $c^v_{w,u} = 0$ while $C^v_{w,u}$ can be nonzero.
The first part of Section 6 is devoted the combinatorics required to generalize Theorem 5.1 to a combinatorial model for the $K$-theoretic structure constants $C^w_{v,u}$. But even without such an explicit rule, we can already state a specialized result that allows the determination of the $C^w_{v,u}$ from their cohomological analogues.

When $\sigma_w \cdot \sigma_u$ expands as a multiplicity-free sum of Schubert classes in $H^*(G/P)$, a result of A. Knutson determines the corresponding expansion of $[O_{X_w}] \cdot [O_{X_u}]$ in $K(G/P)$. Recall that the Möbius function of a poset $P$ is the function $\mu_P : P \times P \to \mathbb{Z}$ uniquely characterized by $\mu_P(x,x) = 1$ and the fact that for all $x \prec y \in P$,

(5.2) \[ \sum_{x \preceq z \preceq y} \mu_P(x,z) = 0. \]

Given a poset $P$, we shall adjoin a minimal element 0 and write $\hat{\mu}_P(x) := -\mu_P(0,x)$.

**Theorem 5.2** (A. Knutson [Knu09, Theorem 3]). Suppose

$$\sigma_w \cdot \sigma_u = \sum_{v \in D} \sigma_v$$

is a multiplicity-free product in $H^*(G/P)$, where $D \subseteq W^P$ represents the set of $v \in W^P$ that appear. Write $P := \{y \in W^P : y \geq v, \text{ for some } v \in D\}$. Then the corresponding expansion in $K(G/P)$ is

$$[O_{X_w}] \cdot [O_{X_u}] = \sum_{y \in P} \hat{\mu}_P(y)[O_{X_y}].$$

**Example 5.3.** Continuing **Example 2.2**, for $a = b = 2$, we have

$$
\begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix}^2 = \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} - \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O} \\
\mathcal{O}
\end{bmatrix}.
\end{bmatrix}

In fact, as we will prove in a forthcoming paper, the square of a structure sheaf indexed by a rectangle is always multiplicity-free.

We will be particularly interested in multiplicity-free products in $K(G/P)$. Conveniently, by **Theorem 5.2**, to determine multiplicity-freeness in $K(G/P)$, it suffices to check the corresponding statement in $H^*(G/P)$ and then apply the theorem.

**Remark 5.4.** It is not the case that a multiplicity-free product in cohomology necessarily yields a multiplicity-free product in $K$-theory. For example, in $Gr(3,6)$, we have

$$\sigma_{\mathcal{O}_{2\times2}} \cdot \sigma_{\mathcal{O}_{2\times2}} = \sigma_{\mathcal{O}_{2\times2}} + \sigma_{\mathcal{O}_{2\times2}} + \sigma_{\mathcal{O}_{2\times2}}$$

but

$$
\begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix} \cdot \begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix} = \begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix} + \begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix} - 2 \begin{bmatrix}
\mathcal{O}_{2\times2} \\
\mathcal{O}_{2\times2}
\end{bmatrix}.
\end{bmatrix}
$$

However, if the cohomological product is multiplicity-free with a single term, i.e.,

$$\sigma_w \cdot \sigma_u = \sigma_v,$$
then it is immediate from Theorem 5.2 that the $K$-theoretic product will also have a single term:

$$[O_{X_w}] \cdot [O_{X_u}] = [O_{X_v}].$$

### 6. Combinatorics of Structure Coefficients

In this section we introduce the combinatorial tools developed in the study of $K$-theoretic Schubert calculus by H. Thomas and A. Yong [TY09b], E. Clifford, H. Thomas, and A. Yong [CTY14], and A. Buch and M. Samuel [BS16]. The main result we wish to review is a combinatorial formula for the $K$-theoretic structure coefficients $C_{v,w}^u$ in the style of Theorem 5.1. The role of standard tableaux is now played by increasing tableaux.

#### 6.1. Increasing Tableaux

Following [BS16], we generalize the language of increasing tableaux from the introduction. Fix a finite poset $P$ with order relation $\prec$ and an alphabet $A$ (assume the symbol $\bullet \not\in A$). For a skew shape $v/w$, a tableau of shape $v/w$ on the alphabet $A$ is a map $T : v/w \to A$.

**Definition 6.1.** Let $A$ be a totally-ordered alphabet with order relation $<$. An increasing tableau of shape $v/w$ on the alphabet $A$ is a strictly order-preserving map $T : v/w \to A$, that is if $\alpha \prec \beta$ in $v/w$ then $T(\alpha) < T(\beta)$. We write $IT_A(v/w)$ for the set of all such maps.

For two disjoint alphabets $A, B$ with $T \in IT_B(w)$ ("$B$" for below) and $U \in IT_A(v/w)$ ("$A$" for above), we write $T \sqcup U$ for the increasing tableau in $IT_{B \sqcup A}(v/w)$, where $B \sqcup A$ is totally ordered so that $b < a$ for all $b \in B$ and $a \in A$. We define $IT(v/w) := \bigcup_{m=1}^{\infty} IT^{(m)}(v/w)$ and set $T_{v/w}^{\min}$ to be the componentwise minimal increasing tableau in $IT(v/w)$. We call $T_{v/w}^{\min}$ the minimal increasing tableau of shape $v/w$ (see Figure 9(a) for an example); it will play an important role in the sequel.

In special cases, the notions of increasing tableaux and $P$-partitions are simply related, as was first observed in [DPS17].

**Proposition 6.2** ([DPS17, Theorem 4.1]). For a ranked poset $P$ with all maximal chains of the same length $ht(P)$, there is a bijection between plane partitions of height $p$ and increasing tableaux in the alphabet $[1, \ell + ht(P)]$:

$$PP^{[\ell]}(P) \simeq IT^{(\ell + ht(P))}(P).$$

**Proof.** With our conventions, a bijection from plane partitions to increasing tableaux is evidently given by adding $i$ to the labels of the elements on the $i$th rank. \qed

Since all of the posets in Theorem 1.3 are of the required form, by Proposition 6.2 we may henceforth deal only with increasing tableaux. The significant advantage that increasing tableaux enjoy over $P$-partitions is that increasing tableaux are equipped with a well-developed theory of $K$-theoretic jeu-de-taquin [TY09a, TY09b, CTY14, BS16], a theory we now explore.

#### 6.2. Jeu-de-Taquin and Other Games
6.2.1. **Jeu-de-Taquin.** Given a shape $v/w \subseteq P$, a tableau $T$ of shape $v/w$ on $A$, and $a \in A$, we let

$$T_a := \{ \alpha \in v/w : \alpha \text{ covers or is covered by some } \beta \text{ for which } T(\beta) = a \}.$$ 

For two letters $a, b \in A$, we may "exchange" them in $T$ to obtain a new tableau

$$\text{swap}_{a,b}(T)(\alpha) := \begin{cases} a & \text{if } T(\alpha) = b \text{ and } \alpha \in T_a; \\ b & \text{if } T(\alpha) = a \text{ and } \alpha \in T_b; \\ T(\alpha) & \text{otherwise.} \end{cases}$$

If we remove a set of maximal elements from $w$, we may extend the tableau $T$ on $v/w$ to a tableau $T'$ of shape $v/w'$ by setting $T'(\alpha) := \bullet$ for $\alpha \in w/w'$. Given an increasing tableau $T$ of shape $v/w$ on the totally-ordered alphabet $A$, the *slide* of $T$ into $w/w'$ is given by

$$\text{jdt}_{w/w'}(T) := \left( \prod_{\alpha \in A} \text{swap}_{\alpha,\bullet} \right)(T'),$$

where the product is in the given linear ordering for $A$, and where we restrict the domain of $\text{jdt}_{w/w'}(T)$ to the subset $v'/w' := \{ \alpha \subseteq v/w' : \text{jdt}_{w/w'}(T)(\alpha) \neq \bullet \}$. This procedure is invertible and hence bijective.

**Example 6.3.** The following illustration is an example of a slide for $A = 1 < 2 < 3 < 4 < 5 < 6$ (see Example 1.6 for several other illustrations). Here, we suppress mention of $\text{swap}_{1,\bullet}$ and $\text{swap}_{6,\bullet}$, as they act trivially in this example.

When $T \in ST(v/w)$ and $w/w'$ is a single box, this process recovers the usual notion of *jeu-de-taquin* introduced by M.-P. Schützenberger. Two tableaux $T$ and $T'$ are called *jeu-de-taquin equivalent* if they are related by a sequence of slides and inverse slides.

6.2.2. **Rectification.** Let $T \in IT^{(m)}(w)$ be an increasing tableau and set

$$w_i := \{ \alpha \in w : T(\alpha) \leq m - i \},$$

so that $w_0 = w$ and $w_m = \emptyset$. The $T$-**rectification** of the skew increasing tableau $U \in IT^{A}(v/w)$ is the straight-shaped tableau

$$\text{rect}_T(U) := \left( \prod_{i=0}^{m-1} \text{jdt}_{w_i/w_{i+1}} \right)(U).$$

In other words, the $T$-rectification of $U$ uses $T$ to determine the *rectification order*: which elements of $w$ become $\bullet$s at each stage in the rectification. **Example 6.3** is an example of rectification, as is the sequence of slides in Section 1.4. In the latter example, the rectification order is determined by the minimal tableau of shifted shape $w = (3,2,1)$.

Given $U \in IT^{A}(v/w)$ and $T, T' \in IT^{[m]}(w)$, it is possible that $\text{rect}_T(U) \neq \text{rect}_{T'}(U)$. A *unique rectification target (URT)* is an increasing tableau $R$ of straight shape such that if $\text{rect}_T(U) = R$ for some $T \in IT(w)$, then $\text{rect}_T(U) = R$ for all $T' \in IT(w)$. In such cases where the tableau prescribing rectification order does not matter, we may simply write $\text{rect}(U) = R$. 
Theorem 6.4 ([BS16, Theorem 3.12]). For \( w \) any straight shape in a minuscule poset, the minimal tableau \( T_{w}^{\text{min}} \) is a URT.

For \( G/P \) minuscule and \( w, u \leq v \in W^P \), define
\[
C^v_{w,u} = C^v_{w,u} := \{ T \in \Infusion(v/w) : \text{rect}(T) = T_{u}^{\text{min}} \}
\]
to be the set of increasing tableaux of shape \( v/w \) that rectify to the minimal tableau of shape \( u \). We can now state A. Buch and M. Samuel’s elegant combinatorial rule—building on seminal work of H. Thomas and A. Yong [TY09b] to generalize Theorem 5.1—for the structure coefficients \( C^v_{w,u} \) of Equation (5.1).

Theorem 6.5 ([BS16, Corollary 4.8]). For \( G/P \) minuscule,
\[
(-1)^{|w|-|v|-|u|} C^v_{w,u} = \left| C^u_{w,u} \right|.
\]

6.2.3. The Infusion Involution. Instead of discarding the rectification order \( T \) when performing rectification, we can consider what happens to the pair \( (T, U) \) as we move \( U \) past \( T \). We keep track of the two tableaux using two disjoint alphabets: \([m] \) and \([m] := \{ T \in 2 \times \cdots \times k \} \). For \( U \in \Infusion^{[m]}(v/w) \), we will write \( U \) to denote the increasing tableau in \( \Infusion^{[m]}(v/w) \) obtained by sending \( i \mapsto i \).

Let \( T \in \Infusion^{[i]}(w) \) and \( U \in \Infusion^{[j]}(v/w) \). Informally, we will glue the tableau \( T \) on the alphabet \([7]\) to the bottom of the tableau \( U \) on \([j]\) and then slide one alphabet past the other, so that the total ordering
\[
\{7\} \cup \{j\} = 1 < 2 < \cdots < 7 < 1 < 2 < \cdots < j
\]
becomes
\[
\{j\} \cup \{7\} = 1 < 2 < \cdots < j < 1 < 2 < \cdots < 7.
\]
Formally, the infusion involution of \( (T, U) \in \Infusion^{[i]}(w) \times \Infusion^{[j]}(v/w) \) is the pair of tableaux \( (U', T') \in \Infusion^{[i]}(u) \times \Infusion^{[j]}(v/u) \) defined by
\[
U' \sqcup T' = \left( \prod_{a=1}^{i} \prod_{b=j}^{1} \text{swap}_{a,b} \right) (T \sqcup U).
\]
See Figure 7 for an example.

Theorem 6.6 ([TY09b, Theorem 3.1]). Infusion is an involution. That is, for \( T \in \Infusion(w) \) and \( U \in \Infusion(v/w) \), we have
\[
(\text{infusion} \circ \text{infusion})(T, U) = (T, U).
\]

6.3. Relations and Equivalence. For \( T \) a standard or increasing tableau (in English tableau orientation, as in Figure 4 or Figure 9), let \( \text{read}(T) \) be the column reading word obtained by reading the entries in the columns of \( T \) from left to right and bottom to top; where it will not cause confusion, we will abbreviate this to reading word. We wish to consider the set of words on the alphabet of positive integers, up to Knuth, Coxeter-Knuth, \( K \)-Knuth, or weak \( K \)-Knuth equivalences—whose defining relations are given in Figure 8. We note that our “Knuth equivalence” in Figure 8 acts only on triples of distinct letters; it is therefore weaker than the usual notion from the theory of semistandard tableaux, although it agrees with the usual notion for reading words of standard tableaux.

Remarkably, as summarized in Theorem 6.7, these relations on reading words of tableaux exactly mirror jeu-de-taquin slides on the tableaux themselves. As in Remark 3.1 and Section 4.3, recall that “Ferrers tableau” means a tableau of
Figure 7. The infusion involution. On the left, $U$ is shown with black entries and $T$ shown with red, barred entries. The infusion involution of $(T, U)$ is $(U', T')$, where $U'$ is the straight tableau in black on the right and $T'$ is the skew tableau in red on the right.

Figure 8. (Standard) Knuth-like relations, where $a < b < c$ are distinct positive integers and $u$ is a word of positive integers.

Theorem 6.7 ([BS16, Theorems 6.2 and 7.8]).

Two increasing (skew)\{Ferrers shifted Ferrers\} tableaux $T, T'$ are jeu-de-taquin equivalent if and only if $\text{read}(T)$ and $\text{read}(T')$ are \{K-Knuth weakly K-Knuth\} equivalent.
The following proposition records two facts about $K$-Knuth equivalence for use in Section 10.1.

**Proposition 6.8** ([TY09b, Theorem 6.1] and [BS16, Lemma 5.4 and Corollary 6.8]).

1. The longest strictly increasing subsequences of $K$-Knuth equivalent words have the same length.
2. The length of the first row of an increasing Ferrers tableau $T$ of straight shape is the length of the longest strictly increasing subsequence of $\text{read}(T)$.

The *doubling* $T^D$ of a shifted Ferrers tableau $T$ is the Ferrers tableau obtained by reflecting $T$ across the shifted diagonal—note that the shifted diagonal itself is *not* duplicated [BS16, Section 7.1]. This construction is illustrated in Figure 9.

(a): For $u = (3, 2, 1)$, the minimal increasing tableau $T^\text{min}_u$ and $(T^\text{min}_u)^D$:

$$
\begin{array}{ccc}
1 & 2 & 3 \\
3 & 4 & 5 \\
\end{array} \quad \rightarrow \quad 
\begin{array}{ccc}
1 & 2 & 3 \\
2 & 3 & 4 \\
3 & 4 & 5 \\
\end{array}
$$

(b): A partially filled skew shape $\tilde{U}$ and its doubling $\tilde{U}^D$:

$$
\begin{array}{ccc}
1 & 2 & 3 \\
2 & 3 & 4 \\
\end{array} \quad \rightarrow \quad 
\begin{array}{ccc}
1 & 2 & 3 \\
2 & 3 & 4 \\
1 & 2 & 3 \\
\end{array}
$$

**Figure 9.** Examples of doubling. In (b), we have marked in red the strictly increasing subsequence of length at least $k$ from which we derive a contradiction in Proposition 10.4.

The operation of doubling allows us to relate weak $K$-Knuth equivalence to $K$-Knuth equivalence.

**Proposition 6.9** ([BS16, Proposition 7.1]). Let $T$ and $U$ be shifted Ferrers tableaux. If $\text{read}(T)$ and $\text{read}(U)$ are weakly $K$-Knuth equivalent, then $\text{read}(T^D)$ and $\text{read}(U^D)$ are $K$-Knuth equivalent.

7. A Bijective Framework for Doppelgängers

Our bijective framework for doppelgängers is based on the equivalence of a product in $K(G/P)$ and a bijection between a set and a multiset of increasing tableaux. In this section we introduce this framework; Sections 8 to 10 will then be devoted to specializing Theorem 7.1 to prove Theorem 1.3.

**Theorem 7.1.** Suppose $G/P$ is a minuscule variety and $u \leq v \in W_P$. If

$$(7.1) \quad [\mathcal{O}_{X_u}] \cdot [\mathcal{O}_{X_v}] = \sum_x C^x_{\xi,u} [\mathcal{O}_{X_x}],$$

then $C^x_{\xi,u} = C^x_{\xi,v}$ and, for any $m \in \mathbb{Z}_{>0}$, $\text{rect}_{T^\text{min}}$ gives a bijection

$$|T^{[m]}(v/u)| \simeq \bigcup_{x \subseteq v} \left( C^x_{\xi,u} \times |T^{[m]}(x)| \right).$$
The idea behind the proof of Theorem 7.1 is illustrated in Figure 10.

Proof. We first note that \( C_{\tilde{v}, \tilde{u}} = C_{v, u} \) by the \( S_3 \)-symmetry of \( K \)-theoretic Littlewood-Richardson coefficients for minuscule varieties (cf. [Knu10]).

Consider \( T' \in IT^{[m]}(v/u) \). We have

\[
\text{infusion}(T_{\min}^u, T') = (T, U),
\]

for some \( x \subseteq v \), some \( T \in IT^{[m]}(x) \) and some \( U \in IT^{[m]}(v/x) \). Since \( \text{rect}_T(U) = T_{\min}^u \), we have \( U \in C_{\tilde{v}, \tilde{u}} \). But infusion is an involution by Theorem 6.6, so that \( \text{rect}_{T_{\min}^u} \) is an injection

\[
IT^{[m]}(v/u) \hookrightarrow \bigcup_{x \subseteq v} C_{\tilde{v}, \tilde{u}} \times IT^{[m]}(x).
\]

Conversely, for \( x \subseteq v \), \( U \in C_{\tilde{v}, \tilde{u}} \) and \( T \in IT^{[m]}(x) \), we have

\[
\text{infusion}(T, U) = (T_{\min}^u, T') \in IT(u) \times IT^{[m]}(v/u),
\]

for a unique \( T' \). This shows that \( \text{rect}_{T_{\min}^u} \) is also surjective, and hence bijective. □

In the special case when the product in \( K(G/P) \) is multiplicity-free, so that each \( C_{\tilde{v}, \tilde{u}} \) only has one element, Theorem 7.1 specializes to a bijective statement involving only sets of increasing tableaux. This is illustrated in Example 1.6 and Figure 10.

**Theorem 7.2.** Fix \( m \in \mathbb{Z}_{>0} \) a positive integer and \( u \subseteq v \) order ideals in a minuscule poset. Suppose that the product \( [O_{X_v}] \cdot [O_{X_u}] \) is multiplicity-free or equivalently that \( |C_{\tilde{v}, \tilde{u}}| \leq 1 \) for every \( x \subseteq v \). Then \( \text{rect}_{T_{\min}^u} \) gives a bijection

\[
IT^{[m]}(v/u) \simeq \bigcup_{x \in C_{\tilde{v}, \tilde{u}} \neq 0} IT^{[m]}(x).
\]

Let \( \ell = m - \text{ht}(v/u) \). If all maximal chains of \( v/u \) are of equal length, and the same is true for each \( x \) with \( C_{\tilde{v}, \tilde{u}} \neq 0 \), then there is a bijection

\[
\text{PP}^{[\ell]}(v/u) \simeq \bigcup_{x \in C_{\tilde{v}, \tilde{u}} \neq 0} \text{PP}^{[\ell + \text{ht}(v/u) - \text{ht}(x)]}(x).
\]

Proof. The first statement is immediate from Theorem 7.1, and the second statement follows from the first by Proposition 6.2. □

Specializing further to the case when the product is multiplicity-free with a single term, we obtain the following geometric corollary.
Corollary 7.3. In a minuscule variety $G/P$, if the Richardson variety $X^v$ is rationally equivalent to the opposite Schubert variety $X^x$ (or, equivalently, if both represent the same class in the Chow ring $A^*(G/P)$), then there is a bijection
\[ IT^{[m]}(v/u) \simeq IT^{[m]}(x). \]

Proof. In this case, the product $\sigma_\theta \cdot \sigma_u$ expands in the Schubert basis of $H^*(G/P)$ as the single term $\sigma_x$. Hence, by Remark 5.4, we also have
\[ [O_{X^v}] \cdot [O_{X^u}] = [O_{X^x}]. \]
Now, conclude by Theorem 7.2. \qed

We finally may restrict Theorem 7.2 to the cohomology ring $H^*(G/P)$, which gives bijections of standard tableaux.

Corollary 7.4. Fix $m \in \mathbb{Z}_{>0}$ a positive integer and $u \subseteq v$ order ideals in a minuscule poset. Suppose $|C_{x,u}| \leq 1$ for every $x \subseteq v$. Then $\text{rect}_{\text{min}}$ restricts to a bijection
\[ ST(v/u) \simeq \bigcup_{x \subseteq C_{x,u} \neq 0} ST(x). \]

Proof. The bijection in Theorem 7.2 obviously restricts to the set of standard tableaux. \qed

8. Coincidental Root Posets

In this section, we develop the posets $\Phi^+_Y$ appearing in Theorem 1.3.

Definition 8.1. We call the Coxeter-Cartan types $A_n$, $B_n$, $H_3$, and $I_2(m)$ the coincidental types.

A. Miller observed that these are exactly those types for which the degrees $d_1 < d_2 < \cdots < d_n$ of the Coxeter group $W$ form an arithmetic sequence [Mil15]. The coincidental types have many remarkable properties, and many enumerative questions are “more uniform” when restricted from all Coxeter-Cartan types to just the coincidental types. Such enumerative results include:

- the number of $k$-dimensional faces of the generalized cluster complex [FR05];
- the number of saturated chains of length $k$ in the noncrossing partition lattice [Rea08];
- the number of reduced words for $w_o$ [Sta84, EG87, Hai92, Wil13];
- the number of multitriangulations [CLS14]; and
- the Coxeter-biCatalan numbers [BR15].

8.1. Crystallographic Root Posets. Since the root system of type $B_n$ is crystallographic, its root poset is defined by Equation (3.1). Examples are given in Figure 1; $\Phi^+_B$ is a shifted double staircase when drawn as a shifted Ferrers shape.

More generally, using the conventions of Figure 5, let
\[ b_{k,n} := (s_1 s_2 \cdots s_{n-k})^k \in W(B_{n-k}) \]
for $n \geq 2k$. The poset $\Phi^+_{B_{k,n}}$ is
\[ \Phi^+_{B_{k,n}} := \Phi^+_{B_{n-k}} \cap b_{k,n}, \]
the restriction of $\Phi^+_{B_{n-k}}$ to the roots that are inversions of the Weyl group element $b_{k,n}$. As a special case, since $b_{n,2n} = w_o \in W(B_n)$, we have $\Phi^+_{B_n} = \Phi^+_{B_{n,2n}}$. When drawn as a shifted Ferrers shape, $\Phi^+_{B_{k,n}}$ may be described as the shifted trapezoid, with corresponding strict integer partition $(n-1, n-3, \ldots, n-2k+1)$.
In general, for \( Y \in \{B_{k,n}, H_3, I_2(2n)\} \), we will write
\[
\omega(Y) := \begin{cases} 
\omega_0 \in W(Y) & \text{if } Y \in \{H_3, I_2(m)\} \\
b_{k,n} \in W(B_{n-k}) & \text{if } Y = B_{k,n}
\end{cases}
\]

8.2. Non-Crystallographic Root Posets. It remains to construct “root posets” in the noncrystallographic types \( H_3 \) and \( I_2(m) \) for \( m \neq 2, 3, 4, 6 \). In crystallographic types, it is a remarkable fact (uniformly proven by B. Kostant [Kos59]) that the sizes of the ranks of \( \Phi^+ \) and the degrees \( d_1, d_2, \ldots, d_n \) of \( W \) form conjugate partitions under the identity [Hum92, Theorem 3.20]
\[
|\{\alpha \in \Phi^+ : \text{ht}(\alpha) = i\}| = |\{j : d_j > i\}|
\]

The obvious application of Equation (8.2) does not yield a root poset satisfying this condition in the non-crystallographic types. For example, if \( \phi := \frac{1+\sqrt{5}}{2} \), then in the basis of simple roots,
\[
\Phi^+_{I_2(5)} = \{(1,0),(0,1),(1,\phi),(\phi,1),(\phi,\phi)\}
\]
which would be ordered by Equation (3.1) to have Hasse diagram \( \) so that it has two elements of rank one, two elements of rank two, and one element of rank three. On the other hand, since the degrees of \( I_2(5) \) are 2 and 5, Equation (8.2) predicts two elements of rank one, and one element for each rank greater than one.

On the basis of Equation (8.2) and a few other criteria from Coxeter-Catalan combinatorics, D. Armstrong constructed surrogate root posets in types \( H_3 \) and \( I_2(m) \) with desirable behavior [Arm09]. For more details, see [CS15, Section 3] (which includes a construction of \( \Phi_{H_3}^+ \) using a folding argument).

We will construct these root posets using the fully commutative theory reviewed in Section 4, and refer the reader to the noncrystallographic part of Figure 5 for the labeling conventions of the Coxeter-Dynkin diagram. For convenience, we now work with reflections instead of roots.

8.2.1. \( I_2(m) \). In type \( I_2(m) \), the root poset is a natural generalization of the root posets for the crystallographic dihedral types \( A_1 \times A_1, A_2, B_2, \) and \( G_2 \).

The Coxeter group \( W = W(I_2(m)) \) has two generators, \( s = s_1 \) and \( t = s_2 \). \( W \) has a fully-commutative maximal parabolic quotient \( W^J \), where \( J = \{t\} \). The longest element of \( W^J \) has one reduced word: \( w_0^J = \underbrace{sts\cdots}_{m-1 \text{ letters}} \). The heap for \( w_0^J \) is therefore a chain of length \( m - 1 \), whose vertices are canonically labeled by the reflections coming from the corresponding letter of the word for \( w_0^J \): \( s, sts, ststs, \ldots \).

This leaves only the reflection \( t \) unspecified—but in order for the full poset to satisfy Equation (8.2), we conclude that \( sts \) covers \( t \). See Figure 1 for an example.

8.2.2. \( H_3 \). We note that \( W(I_2(5)) \) is the maximal parabolic subgroup of \( W = W(H_3) \) generated by \( J = \{s_1, s_2\} \). By the previous section, we therefore obtain the root poset of the parabolic subgroup \( W(I_2(5)) \), which ought to be the restriction of the full root poset of \( H_3 \) to that parabolic subgroup. Now the parabolic quotient \( W^J = W(H_3)/W(I_2(5)) \) has a maximal element that is fully commutative (see the classification in Figure 5). This fact allows us to canonically label the heap of \( w_0^J = s_3s_2s_1s_3s_2s_1s_3s_2s_1 \)

by the corresponding reflections. In order to satisfy Equation (8.2), we let \( t < s_3ts_3 \) for all reflections \( t \in W_J \) such that \( s_3ts_3 \neq t \). This poset is illustrated in Figure 11, and has been shown in [CS15] to be the unique poset satisfying a list of six natural conditions.
9. Poset Embeddings

Fix
\[(X,Y,Z) \in \left\{ \left( \text{Gr}(k,n), B_{k,n}, OG(n,2n) \right), \left( \text{OG}(6,12), H_3, G_\omega(O^3,O^6) \right), \left( Q^2_n, I_2(2n), Q^4_n - 2 \right) \right\} \]
a triple from Figure 2. We will refer to such a triple by its label (B), (H), or (I), as in Figure 2. Here again, \(X\) and \(Z\) stand for minuscule varieties, while \(Y\) is a bookkeeping device specifying a Cartan type. Following [TY09a], we formalize Figure 3 by embedding the doppelgänger posets \(\Lambda_X\) and \(\Phi_Y\) into the ambient minuscule poset \(\Lambda_Z\). That is, we explicitly characterize \(v/u := \Theta(\Lambda_X) \subseteq \Lambda_Z\) and \(w := \chi(\Phi_Y) \subseteq \Lambda_Z\).

9.1. \(X\) in \(Z\): Embedding Minuscule Varieties. A minuscule flag variety is specified by a Cartan type and a minuscule weight, as in Figure 5. For \(X\) a minuscule flag variety, let \(\text{Cart}(X)\) be the corresponding Cartan type, write \(W(\text{Cart}(X))\) for the Weyl group \(W(\text{Cart}(X))\), and let \(W^X\) be the corresponding maximal parabolic quotient of \(W(X)\).

\[
\begin{align*}
\Theta_B & : \Delta(A_{n-1}) \leftrightarrow \Delta(D_n) \\
\Theta_H & : \Delta(D_6) \leftrightarrow \Delta(E_7) \\
\Theta_I & : \Delta(D_m) \leftrightarrow \Delta(D_{2m-2})
\end{align*}
\]

Figure 12. Embedding \(\Delta(\text{Cart}(X))\) into \(\Delta(\text{Cart}(Z))\).

Figure 12 illustrates the following embeddings of Dynkin diagrams, specified as an injection of the simple roots of \(\text{Cart}(X)\) into the simple roots of \(\text{Cart}(Z)\):

\[
\begin{align*}
\Theta_B & : \Delta(A_{n-1}) \rightarrow \Delta(D_n) \\
\Theta_H & : \Delta(D_6) \rightarrow \Delta(E_7) \\
\Theta_I & : \Delta(D_m) \rightarrow \Delta(D_{2m-2})
\end{align*}
\]

\[
\begin{align*}
\alpha_i & \mapsto \alpha_{i+1}, \\
\alpha_1 & \mapsto \alpha_2, \alpha_2 & \mapsto \alpha_3, \alpha_3 & \mapsto \alpha_4, \\
\alpha_6 & \mapsto \alpha_7, \alpha_7 & \mapsto \alpha_8, \alpha_8 & \mapsto \alpha_9,
\end{align*}
\]

\[
\begin{align*}
\alpha_i & \mapsto \alpha_{i+1}, \\
\alpha_1 & \mapsto \alpha_2, \alpha_2 & \mapsto \alpha_3, \alpha_3 & \mapsto \alpha_4, \\
\alpha_6 & \mapsto \alpha_7, \alpha_7 & \mapsto \alpha_8, \alpha_8 & \mapsto \alpha_9,
\end{align*}
\]
We drop the subscript on $\Theta$ when the interpretation is clear from context. These embeddings extend by linearity to injections of the full root system

$$\Theta : \Phi(Cart(X)) \hookrightarrow \Phi(Cart(Z))$$

and (under the correspondence between roots and reflections) to injections of the associated Weyl groups

$$\Theta : W(X) \hookrightarrow W(Z).$$

(Our abuse of notation, in calling all of these maps $\Theta$, should cause no confusion in context.)

Following [TY09a], the next proposition states that these embeddings of Dynkin diagrams actually induce embeddings of minuscule flag varieties. Using the Bruhat cell decomposition of Equation (3.2) and results of [TY09a], it suffices to embed the parabolic Weyl group quotients in a sufficiently nice way.

**Proposition 9.1** (After [TY09a]). There is an embedding $\Theta : X \hookrightarrow Z$ of minuscule varieties such that

$$\Theta(W^X) = \{ux : x \in W^X\} \subseteq W^Z,$$

for some $u \in W^Z$.

**Proof.** We first characterize $u \in W^Z$ in each of the three cases.

1. (B) $u$ is the longest element of the parabolic quotient $W(D_k)^{(1)}$, explicitly identified in Section 4.3.3.
2. (H) $u := s_7s_6s_5s_4s_3s_1$; and
3. (I) $u := s_{2m}s_{2m-1} \cdots s_{m+2}$.

One checks case-by-case that if $x \in W^X$, then $ux \in W^Z$ by examining the corresponding heaps. These routine but tedious checks prove the containments in the proposition, which establish the analogues of [TY09a, Corollary 6.7 and Lemma 6.8] in these settings. The equality now follows from [TY09a, Proposition 6.1].

We deduce that there is an embedding of the corresponding minuscule posets.

**Corollary 9.2.** For

$$(X, Z) \in \begin{cases} (\text{Gr}(k, n), \text{OG}(n, 2n)), \\ (\text{OG}(6, 12), \text{G}_w(\Delta^3, \Omega^6)), \\ (Q^{2n}, Q^{4n-2}) \end{cases}$$

from any row of Figure 2, there are poset embeddings $\Theta : \Lambda_X \hookrightarrow \Lambda_Z$.

**Proof.** Let $v := uw_X^Z \in W^Z$, where $w_X^Z$ is the longest element of $W^X$. Since $w_X^Z$ is fully commutative, by Theorem 4.4 and Proposition 9.1, $\Lambda_X$ embeds in $\Lambda_Z$ as the poset $\Lambda/\Lambda$.

**9.2. Y in Z: Embedding Root Posets.** We now embed the root posets of the coincidental types $\Phi^+_Y$ into the ambient minuscule posets $\Lambda_Z$. We find the existence of these embeddings mysterious; unexpectedly, the element $w \in W(Z)$ whose heap $w$ coincides with $\Phi^+_Y$ has the same number of reduced words as $w_0(Y) \in W(Y)$.

**Proposition 9.3.** For

$$(Y, Z) \in \begin{cases} (B_k, n, \text{OG}(n, 2n)), \\ (H_3, \text{G}_w(\Delta^3, \Omega^6)), \\ (I_2(2n), Q^{4n-2}) \end{cases}$$

from any row of Figure 2, there is a poset embedding $\chi : \Phi^+_Y \hookrightarrow \Lambda_Z$, so that $\chi(\Phi^+_Y)$ has straight shape $w$ for some $w \in W(Z)$, and such that

$$\text{Red}(w_0(Y)) \simeq \text{Red}(w),$$

where $w_0(Y)$ is the element defined in Equation (8.1) with inversion set $\Phi^+_Y$. 
Proof. We first characterize the elements \( w \in W(Z) \) in each of the three cases.

\[
\begin{align*}
(B) \quad w &:= \prod_{j=1}^k (s_{1,2}(j) \prod_{i=3}^{n-2+2} s_i), \text{ where } s_{1,2}(j) = \begin{cases} 
 s_1 & \text{if } j \text{ is odd} \\
 s_2 & \text{if } j \text{ is even} 
\end{cases} \\
(H) \quad w &:= s_1 s_3 s_4 s_6 s_8 s_3 s_5 s_6 s_7 s_3 s_8 s_1, \\
(I) \quad w &:= \left( \prod_{j=3}^{2n} s_j \right)^{-1} (s_1 s_2).
\end{align*}
\]

The statement that \( \text{Red}(w_u(Y)) \cong \text{Red}(w) \) follows for (B) by [Kra89, Hai92, BHRY14] using the poset isomorphism between \( \Lambda_{\text{OG}(n,2n)} \) and \( \Lambda_{\text{LG}(n-1,2n-2)} \). For (I) and (H), this is an easy but unenlightening check [Wil13]. \( \square \)

**Remark 1.8.** Note that, in contrast to the coincidental root posets, the graphs underlying the root posets of types \( D_n \) \((n > 5)\), \( E_6 \), \( E_7 \), \( E_8 \), and \( F_4 \) are nonplanar, and hence cannot embed in any minuscule poset.

10. Applications: Doppelgängers

As in Section 9, fix

\[
(X,Y,Z) \in \left\{ (\text{Gr}(k,n), B_{k,n}, \text{OG}(n,2n)), \right. \\
\left. (\text{OG}(6,12), H_3, G_2(\mathbb{Q}^3, \mathbb{Q}^6)), \right. \\
\left. (\mathbb{Q}^{2n}, I_2(2n), \mathbb{Q}^{4n-2}) \right\}
\]

a triple from Figure 2. We continue to refer to such a triple by its label (B), (H), or (I), as in Figure 2. We recall that \( \Theta \) is the specified embedding of the doppelgänger minuscule poset \( \Lambda_X \) in \( \Lambda_Z \), \( \chi \) is the specified embedding of the coincidental root poset \( \Phi_Y^\dagger \), and that we denote the corresponding shapes inside the ambient minuscule poset \( \Lambda_Z \) as

\[
v/u := \Theta(\Lambda_X) \quad \text{and} \quad w := \chi(\Phi_Y^\dagger).
\]

In all three cases, we will deduce Theorem 1.3 from Theorem 7.2 by showing that \( \mathcal{C}_{\nu,u} \) has a unique element and that \( \mathcal{C}_{\nu,u} = \emptyset \) for \( x \neq w \).

**Remark 10.1.** Geometrically, this amounts to showing that \( [\mathcal{O}_{X_x}] \cdot [\mathcal{O}_{X_u}] = [\mathcal{O}_{X_w}] \) in the \( K \)-theory ring \( K(Z) \). Indeed, by Remark 5.4, it would be enough to establish that \( \sigma_v \cdot \sigma_u = \sigma_w \) in \( H^*(Z) \), or equivalently that \( [X_w^v] = [X^w] \in A^*(Z) \). So in fact, for example, Theorem 1.3(B) (providing R. Proctor’s missing bijection) essentially follows from combining the geometric fact of Remark 5.4, the easy combinatorial observation of Theorem 7.2, and M. Haiman’s bijection of standard tableaux from Remark 1.8.

10.1. **(B): Rectangles and Shifted Trapezoids.** Sections 4, 8 and 9 identify the following shapes for \( Y = \Phi^+_{B_{k,n}} \) and \( X = \text{Gr}(k,n) \):

\[
w = (n - 1, n - 3, \ldots, n - 2k + 1) \ast \text{ is a shifted trapezoid, and} \\
v/u = (n - k, n - k, \ldots, n - k) \text{ is a } k \times (n - k) \text{ rectangle. Then} \\
u = (k - 1, k - 2, \ldots, 1) \ast \text{ is a shifted staircase and} \\
v = (n - 1, n - 2, \ldots, n - k) \ast.
\]

Figure 13 illustrates examples of \( v/u \) and \( w \). Write \( a := 2k - 3 \) and let \( U \) be the increasing anti-straight Ferrers tableau of shape \( v/w \) obtained by labeling each southwest-to-northeast diagonal of the staircase \( v/w \) with consecutive increasing integers, where the bottom row is labeled with the odd numbers from 1 to \( a \).

Figure 9(a) and Figure 14 illustrate examples of \( T_{\nu}^{\min} \) and \( U \).

We begin by characterizing a property of the reading word of any tableau that rectifies to \( T_{\nu}^{\min} \).
Lemma 10.2. For $a = 2k - 3$, let $\pi \in S_a$ be the permutation with one-line notation $[2, 4, \ldots, a+1, 1, 3, \ldots, a]$. Then any tableau $\tilde{U}$ that rectifies to $T_{u}^{\min}$ has a reading word $\text{read}(\tilde{U})$ whose Demazure product is $\pi$. In particular, since $\text{len}(\pi) = \binom{k}{2}$, any such $\tilde{U}$ must have at least $\binom{k}{2}$ cells.

Proof. It is easy to see that the reading word $\text{read}(T_{u}^{\min})$ is a reduced word of the permutation $\pi$. Since $\text{read}(T_{u}^{\min})$ is a reduced word, any weakly $K$-Knuth equivalent word is at least as long (see the weak $K$-Knuth relations in Figure 8). Furthermore, since every reduced word for $\pi$ begins with two commuting letters, the words that are weakly $K$-Knuth equivalent to $\text{read}(T_{u}^{\min})$ have Demazure product $\pi$. We conclude the statement using Theorem 6.7 on the interchangeability of $K$-jeu-de-taquin equivalence of tableaux and $K$-Knuth equivalence of their reading words. \qed

We now consider tableaux whose reading word can be $\pi$. Recall that a permutation $\tau \in S_a$ is vexillary if its one-line notation avoids the pattern 2143; $\tau$ is fully commutative if and only if it avoids the pattern 321; and $\tau$ is Grassmannian if it has at most one descent. A Grassmannian permutation is therefore both vexillary and fully commutative. In particular, the $\pi$ of Lemma 10.2 is a Grassmannian permutation.

Lemma 10.3. For $a = 2k - 3$, let $\pi \in S_a$ be the permutation with one-line notation $[2, 4, \ldots, a+1, 1, 3, \ldots, a]$. There is a unique increasing anti-straight Ferrers tableau $T_{\pi}$ with $\text{read}(T_{\pi}) \in \text{Red}(\pi)$.
Proof. We shall prove the statement more generally for any Grassmannian permutation \( \tau \). As suggested to us by V. Reiner, it suffices to prove that there is a unique such (straight) Ferrers tableau, since if \( T'_s \) is the tableau obtained from \( T_r \) by reflecting across the antidiagonal and replacing \( s_i \mapsto s_{n-i} \), then \( \text{read}(T'_s) \) is a reduced word for \( w_s w_o \) (both of the patterns 321 and 2143 are stable under conjugation by \( w_o \)).

Since \( \tau \) is vexillary, it is well known that the reduced words of \( \tau \) form a single Coxeter-Knuth equivalence class. Since \( \tau \) is also fully-commutative, we have that, in the absence of braid moves, this Coxeter-Knuth class reduces to an ordinary Knuth equivalence class. But any (semistandard) Knuth equivalence class contains a unique word that is the reading word of a Ferrers tableau [Ful97, Section 2], from which the lemma follows. \( \square \)

Using the constraints provided by Lemma 10.2 and Lemma 10.3, we now show that \( U \) is the unique tableau whose shape is an order filter of \( v \) and that rectifies to \( T_{u}^{\text{min}} \).

**Proposition 10.4.** \( C_{w,u}^\tau = \{ U \} \) and \( C_{x,u}^\tau = \emptyset \) for \( x \neq w \).

**Proof.** We first show that \( U \in C_{w,u}^\tau \). Since \( \text{read}(T_{u}^{\text{min}}) = \text{read}(U) \) and \( T_{u}^{\text{min}} \) is a URT by Theorem 6.4, \( \text{rect}_T(U) = T_{u}^{\text{min}} \) for any \( T \in \text{IT}(w) \) by [BS16, Theorem 7.8]. By definition, we then conclude \( U \in C_{w,u}^\tau \).

Let \( \tilde{U} \in C_{x,u}^\tau \) for some \( x \). We now argue that \( \tilde{U} \) is necessarily of skew shape \( v/w \). By Propositions 6.8 and 6.9, since the shape of the doubling \( (T_{u}^{\text{min}})^D \) is a \((k-1) \times (k-1)\) square (see Figure 9(a)), the longest strictly increasing subsequence in \( \text{read}(\tilde{U}^O) \) is of length \( k-1 \). We claim that this forces the \( r \)th column of \( \tilde{U} \) (from the right) to have at most \( k-r \) cells: if the \( r \)th column of \( \tilde{U} \) has more than \( k-r \) cells, then the \( r \)th row of \( \tilde{U}^O \), along with the last \( r-1 \) entries in the bottom row of \( \tilde{U} \), form a strictly increasing sequence of length at least \( k \) in \( \text{read}(\tilde{U}^O) \). Since there are at least \( \binom{k}{2} \) entries in \( \tilde{U} \) by Lemma 10.2, the shape of \( \tilde{U} \) is \( v/w \). This construction is illustrated in Figure 9(b).

It remains to show that the fillings of \( \tilde{U} \) and \( U \) are equal. By Lemma 10.2, the Demazure product of \( \text{read}(\tilde{U}) \) is \( \pi \). But since \( \text{read}(\tilde{U}) \) has length \( \binom{k}{2} = \text{len}(\pi) \), \( \text{read}(\tilde{U}) \) is then a reduced word for \( \pi \). Since both \( \text{read}(\tilde{U}) \) and \( \text{read}(U) \) are reduced words for the Grassmannian permutation \( \pi \), and both \( \tilde{U} \) and \( U \) have anti-straight shapes, Lemma 10.3 implies \( \tilde{U} = U \), as desired. \( \square \)

By combining Theorem 7.2 and Proposition 10.4, we conclude Theorem 1.3(B).

10.2. (H). For the triple labeled (H), let the tableau \( U \) and its rectification be as illustrated on the left in Figure 15. It is a straightforward but lengthy calculation to verify that \( C_{w,u}^\tau = \{ U \} \) and that \( C_{x,u}^\tau = \emptyset \) for \( x \neq w \). We performed this calculation via computer, explicitly rectifying all applicable tableaux. This case of Theorem 1.3 now follows from Theorem 7.2.

10.3. (I). For the triple labeled (I), the shape \( v/x \) must be an order filter of size \( \lceil \frac{2n-2}{2} \rceil \) in \( v \). There is a unique such order filter in \( v \)—the shape \( v/w \)—and because \( v/w \) is a chain, it has a unique filling that rectifies to \( T_{u}^{\text{min}} \). By Theorem 7.2, this proves the final case of Theorem 1.3. We refer the reader the the illustration on the right in Figure 15.

10.4. Other Doppelgängers. [TY09a, Figure 9] details the embeddings

\[ \Lambda_{OG(5,10)} \hookrightarrow \Lambda_{CP^2} \hookrightarrow \Lambda_{GL(D^3, O^e)}. \]
The three embeddings so specified give three pairs of additional (but completely trivial) doppelgängers.

On the other hand, it is not the case that every embedding of a minuscule poset inside another gives a pair of doppelgängers. For example, one can check that the embedding of $\Lambda_{Gr(2,6)}$ inside $\Lambda_{OP}^2$ indeed corresponds under Theorem 7.1 to a multiplicity-free product in both ordinary cohomology and $K$-theory; however, these products have three and five terms, respectively.

11. Future Work

In [TY05], H. Thomas and A. Yong characterize all multiplicity-free products of Schubert classes in $Gr(k,n)$ (extending work of J. Stembridge [Ste01b]). It is natural to wish to extend this to all minuscule flag varieties; except for the single remaining infinite family (up to isomorphism), this is a finite check.

Problem 11.1. Classify all multiplicity-free products of cohomological Schubert classes in all minuscule flag varieties.

As pointed out Remark 5.4, multiplicity-free products in cohomology are not necessarily multiplicity-free in $K$-theory. It would be interesting to apply A. Knutson’s Theorem 5.2 to classify the latter products. To our knowledge, this is open even in the Grassmannian case (although additional combinatorial tools are available in that case, e.g. [Sni09]).

Problem 11.2. Classify all multiplicity-free products of $K$-theoretic Schubert classes in all minuscule flag varieties.

Given any multiplicity-free product from Problem 11.1 or Problem 11.2, Theorem 7.2 then gives a combinatorial identity. We have not recorded in this paper all such identities—or even all such identities that lead to a pair of doppelgängers.

More generally, it is possible to derive poset identities (relating the number of standard or increasing fillings) by comparing Richardson varieties. V. Reiner,
K. Shaw, and S. van Willigenburg have partial results in this direction for Grassmannians [RSvW07].

**Problem 11.3.** When do the (cohomological or $K$-theoretic) classes of two Richardson varieties have the same expansion into Schubert classes?

11.1. **Another coincidence.** There is one further poset identity involving the last coincidental type, relating $n$-staircases (the root poset of type $A_n$) and shifted $n$-staircases (the cominuscule poset of type $(C_n, 1)$). Although it does not fit directly into our framework, it seems closely related.

Recall that $\Lambda_{LG(n,2n)}$ is the cominuscule poset of type $(C_n, 1)$ (a shifted staircase of order $n$). The **diagonal** of $\Lambda_{LG(n,2n)}$ is the set of its elements labeled by long roots of $\Phi^+_C$. Let $\overline{ST}(\Lambda_{LG(n,2n)})$ denote the product $[2^{n(n-1)/2}] \times ST(\Lambda_{LG(n,2n)})$ (with elements represented as shifted standard tableaux with any set of off-diagonal entries barred), and let $PP^{[2]}(\Lambda_{LG(n,2n)})$ be the subset of $PP^{[2]}(\Lambda_{LG(n,2n)})$ with only even heights on the diagonal. These definitions are illustrated in Example 11.4.

**Example 11.4.** For $n = 2$ and $p = 1$, $\overline{ST}(\Lambda_{LG(2,4)})$ and $PP^{[2]}(\Lambda_{LG(2,4)})$ (first row), and (the duals of) $ST(\Phi^+_A)$ and $PP^{[1]}(\Phi^+_A)$ (second row) are illustrated below. The color white stands for height zero, gray for height one, and black for height two. The modified fillings for $\Lambda_{LG(n,2n)}$ have no barred element nor the color gray in their leftmost columns.

The following theorem summarizes work in [Pur14] and [She99]. The equinumerosity (AP) was first proved *non-bijectively* by R. Proctor [Pro90].

**Theorem 11.5.** There is an explicit (symplectic jeu-de-taquin) bijection between

(AP) \[ PP^{[2]}(\Lambda_{LG(n,2n)}) \simeq PP^{[1]}(\Phi^+_A), \] (J. Sheats [She99])

and there is also an explicit (jeu-de-taquin) bijection between

(AS) \[ ST(\Lambda_{LG(n,2n)}) \simeq ST(\Phi^+_A). \] (K. Purbhoo [Pur14])

We suspect that these poset identities are related to our theory above. In [Pur14], K. Purbhoo describes an embedding

$$\Theta : LG(n, 2n) \hookrightarrow Gr(n, 2n + 1).$$

As a corollary, one obtains a poset embedding $\Theta : \Lambda_{LG(n,2n)} \hookrightarrow \Lambda_{Gr(n,2n+1)}$. Furthermore, there is an embedding $\chi$ of $\Phi^+_A$ inside $\Lambda_{Gr(n,2n+1)}$ given by the element $w := \prod_{j=1}^n \prod_{i=-n-j+1}^{2n-2j+1} s_i \in W(A_{2n}).$

We can embed an element of $ST(\Phi^+_A)$ on the standard alphabet $[m]$ as a standard tableau of shape $\Lambda_{Gr(n,2n)}$ by reflecting across the diagonal and barring this reflection—extending the standard alphabet to $[m] \cup \{m\}$. K. Purbhoo [Pur14] then gives a bijection

$$\text{fold} : ST(\Phi^+_A) \to ST(\Lambda_{LG(n,2n)}).$$

---

3We thank F. Bergeron for pointing out that [RSvW07] was of the same spirit as the problems we have been considering.
using an operation similar to the infusion involution—but rather than completely slide one alphabet past another, he instead *folds* the two alphabets together, so that the total ordering
\[ [m] \sqcup [m] = 1 < 2 < \cdots < m < \overline{m} < \cdots < \overline{2} < \overline{1} \]
becomes the total ordering
\[ [\overline{m}] \sqcup [m] := 1 < \overline{2} < 2 < \cdots < \overline{m} < m. \]

Writing \( P[m](\Lambda_{LG}(n, 2n)) \) for the set of increasing tableaux of shape \( \Lambda_{LG}(n, 2n) \) on the alphabet \([m]\sqcup[m]\) with any set of off-diagonal entries barred, we have an easy bijection
\[
P[p](\Lambda_{LG}(n, 2n)) \simeq P[p+n](\Phi_{A_n}+). \]
The bijection in Proposition 6.2 similarly gives
\[
P[p](\Phi_{A_n}+) \simeq IT[p+n](\Phi_{A_n}^+), \]
and we can perform the embedding of \( IT^{|m|}(\Phi_{A_n}^+) \) into \( IT^{|m|+|\overline{m}|}(Gr(n, 2n)) \) by reflecting and barring, as in the standard case. It is perhaps surprising that the obvious increasing modification of K. Purbhoo’s folding is *not* a bijection between \( IT^{[2p+n-1]}(\Lambda_{LG}(n, 2n)) \) and \( IT^{[p+n]}(\Phi_{A_n}^+) \)—folding may result in barred letters on the diagonal.

**Problem 11.6.** Prove R. Proctor’s identity (Theorem 11.5, (AP)) using a \( K \)-theoretic jeu-de-taquin extension of K. Purbhoo’s bijection (Theorem 11.5, (AS)).

\[
\Lambda_X \leftrightarrow \Lambda_Z \quad \text{fold} \quad \Phi_{A_n}^+ \quad \text{Gr}(n, 2n) \]

**Figure 16.** The analogues of Figures 2 and 3 for an additional identity. On the right is the poset \( \Lambda_{Gr(3,6)} \); the vertices with thick borders correspond to the embedding \( \Theta(\Lambda_{LG(3,6)}) \), while the gray vertices represent \( \chi(\Phi_{A_3}^+) \).

11.2. **Reduced Words.** This relationship between linear extensions and reduced words has two different combinatorial proofs in types \( A_n \) and \( B_n \), which are related in [HY14, BHRY14]. We refer the reader to [Las95] for additional historical context.

- One proof is via modified RSK insertion algorithms due to P. Edelman and C. Greene in type \( A_n \), and W. Kraskiewicz in type \( B_n \) [EG87, Kra89, Lam95]—these insertions read and insert a reduced word for \( w \circ (A_n) \) or \( w \circ (B_n, k) \) letter by letter to produce a standard tableau of shape \( w \) (a staircase or a shifted trapezoid). The bijection is concluded using Theorem 4.3, which canonically bijects \( ST(w) \) with \( \text{Red}(w) \). The map backwards proceeds via *promotion* on the standard tableau encoding a reduced word of \( w \).
- Another proof is via *Little bumps* and *signed Little bumps* [Lit03, BHRY14]. Thinking of a reduced word as a wiring diagram, these methods take a reduced word for \( w \circ (A_n) \) or \( w \circ (B_n, k) \) and systematically eliminate all braid moves—by introducing additional strands—to obtain a reduced word for \( w \). Little bumps may be viewed as a combinatorialization of transition for
Schubert polynomials (due in type $A_n$ to A. Lascoux and M.-P. Schützenberger) [BH95, Bil98].

The Edelman-Greene promotion bijection between standard tableaux of root poset shape and reduced words for the longest element works in all coincidental types, which suggests the following open problem.

**Problem 11.7.** Uniformly develop a theory of insertion algorithms and Little bumps to explain the relation $\text{Red}(w_\circ(Y)) \simeq \text{Red}(w)$ in the coincidental types.

**Remark 11.8.** The first step towards a theory of Little bumps in types $I_2(m)$ and $H_3$ would be the representation of reduced words using wiring diagrams. Such representations exist, since both $W(I_2(m))$ and $W(H_3) \simeq \text{Alt}_5 \times \mathbb{Z}/2\mathbb{Z}$ have (small) permutation representations coming from their actions on the parabolic subgroups identified in Section 8.2; the usual permutation representations of $W(A_n)$ and $W(B_n)$ may be obtained in a similar manner. In analogy to the situation in type $A$ and $B$, using the embeddings of Section 9.2 we expect that the Little bumps of type $H_3$ to take place in $W(E_7)$, while those of $I_2(m)$ should take place in a Weyl group of type $D$.

**Acknowledgements**

Some of the foundational ideas of this paper were developed when ZH, OP and NW attended the “Dynamical Algebraic Combinatorics” workshop at the American Institute of Mathematics (AIM) in March 2015. The authors would like to thank AIM for hosting this workshop, as well as Jim Propp, Tom Roby, and Jessica Striker for their organizational efforts.

The authors are grateful for helpful and inspiring conversations with Bob Proctor, Vic Reiner, and Hugh Thomas and for careful comments from the anonymous referees that helped to improve exposition.

OP is grateful to Kevin Dilks and Jessica Striker for their collaboration on [DPS17], without which the current paper would not exist, and to Francois Ziegler for help understanding the Freudenthal variety.
