EXACT DIATOMIC FERMI-PASTA-ULAM-TSINGOU SOLITARY WAVES WITH OPTICAL BAND RIPPLES AT INFINITY

TIMOTHY E. FAVER AND J. DOUGLAS WRIGHT

Abstract. We study the existence of solitary waves in a diatomic Fermi-Pasta-Ulam-Tsingou (FPUT) lattice. For monatomic FPUT the traveling wave equations are a regular perturbation of the Korteweg-de Vries (KdV) equation’s but, surprisingly, we find that for the diatomic lattice the traveling wave equations are a singular perturbation of KdV’s. Using a method first developed by Beale to study traveling solutions for capillary-gravity waves we demonstrate that for wave speeds in slight excess of the lattice’s speed of sound there exists nontrivial traveling wave solutions which are the superposition an exponentially localized solitary wave and a periodic wave whose amplitude is extremely small. That is to say, we construct nanopteron solutions. The presence of the periodic wave is an essential part of the analysis and is connected to the fact that linear diatomic lattices have optical band waves with any possible phase speed.

We consider the problem of traveling waves in a diatomic Fermi-Pasta-Ulam-Tsingou (FPUT) lattice. The physical situation is this: suppose that infinitely many particles are arranged on a line. The mass of the $j$th (where $j \in \mathbb{Z}$) particle is

$$m_j = \begin{cases} m_1 & \text{when } j \text{ is odd} \\ m_2 & \text{when } j \text{ is even.} \end{cases}$$

Without loss of generality we assume that $m_1 > m_2 > 0$. The position of the $j$th particle at time $\bar{t}$ is $\bar{y}_j(\bar{t})$. Suppose that each mass is connected to its two nearest neighbors by a spring and furthermore assume that each spring is identical to every other spring in the sense that the force exerted by said spring when stretched by an amount $r$ from its equilibrium length $l_s$ is given by

$$F_s(r) := -k_s r - b_s r^2$$

where $k_s > 0$ and $b_s \neq 0$ are specified constants. Such a system is called a “diatomic lattice” or “dimer.” Newton’s law gives the equations of motion for the system:

$$m_j \frac{d^2 \bar{y}_j}{d\bar{t}^2} = -k_s \bar{s}_{j-1} - b_s \bar{s}_{j-1} + k_s \bar{s}_j + b_s \bar{s}_j^2$$

Key words and phrases. FPU, FPUT, nonlinear hamiltonian lattices, periodic traveling waves, solitary traveling waves, singular perturbations, homogenization, heterogenous granular media, dimers, polymers, nanopetrons.

The authors would like acknowledge the National Science Foundation which has generously supported the work through grants DMS-1105635 and DMS-1511488. A debt of gratitude also goes to Nsoki Mavinga and the Department of Mathematics and Statistics at Swarthmore College who hosted JDW during much of the research which went into this document. Additionally, they would like to thank Aaron Hoffman for a huge number of helpful comments and insights. Finally, they dedicate this article to the memory of Malinda Gilchrist, graduate coordinator of Drexel’s math department, colleague, navigator and friend.
where $\bar{s}_j := y_{j+1} - y_j - l_s$.

In the setting where $m_1 = m_2$ it is well-known that there exist localized traveling wave solutions of (0.1), see the seminal articles of Friesecke & Wattis [FW94] and Friesecke & Pego [FP99]. Here we are interested in extending this result to the diatomic case where $m_1 > m_2$. There has been quite a bit of interest in the propagation of waves through polyatomic FPUT lattices. Such systems represent a paradigm for the evolution of waves through heterogeneous and nonlinear granular media (see [Bri53] and [Kev11] for an overview). There are several existence proofs for traveling spatially periodic waves for polyatomic problems [BP13] [Qin15], a number of semi-rigorous asymptotics for solitary wave solutions in various contexts [JSVG13], as well as both formal and rigorous results which state that polyatomic FPUT with periodic material coefficients is well-approximated by the soliton bearing Korteweg-de Vries (KdV) equation over very long time scales [PFR86] [CBCPS12] [GMWZ14]. While all of this previous work strongly suggests that localized traveling waves for polyatomic FPUT will exist, the question of whether a truly localized traveling wave akin to those developed in [FP99] remains open. In this article we demonstrate that the answer to this question—at least for waves which travel at a speed just a bit larger than the speed of sound—is “sort of.”

As it happens, the existence problem is inescapably singular. This is particularly surprising because the existence proof of small amplitude solitary waves for monatomic FPUT in [FP99] goes through using regular perturbation methods. In that article, the equation for the solitary wave’s profile $\phi$ is shown to be equivalent to $\phi = p_c(\phi^2)$ where $p_c$ is a Fourier multiplier operator and $c$ is the speed of propagation. Making the “long wave scaling” $\phi(x) = \epsilon^2 \Phi(\epsilon x)$ and $c = c_{\text{sound}} + \epsilon^2$ yields $\Phi = P_\epsilon(\Phi^2)$. The hinge on which their result turns is the fact that the operator $P_\epsilon$ converges in the operator norm to $(1 - \partial_x^2)^{-1}$ as $\epsilon \to 0^+$. Which means that the traveling wave equation at $\epsilon = 0$ can be rewritten as $\Phi'' + \Phi + \Phi^2 = 0$. This is the traveling wave equation for KdV and has $\text{sech}^2$ type solutions. Moreover, using classical results from quantum mechanics, they show that the linearization of the equation $\Phi = P_0(\Phi^2)$ at the KdV solitary wave results in an operator which is invertible on even functions. This, with the uniform convergence of $P_\epsilon$, allows them to extend the wave’s existence to $\epsilon > 0$ using a quantitative inverse function theorem.

This process goes awry in the diatomic setting. In this case the dispersion relation for the linearization of (0.1) has two parts. The “acoustic” band, which is more or less just like the dispersion relation for the monatomic problem, and the “optical” band which does not exist in the monatomic problem at all. Roughly speaking, we are able to decompose our problem into a pair of equations, one for the acoustic part and another for the optical part. The analysis for the acoustic part goes forward along lines much like in the monatomic case of [FP99]; it limits to a KdV traveling wave equation. On the other hand, the equation for the optical part is classically singularly perturbed in the sense that the highest derivative of the unknown is multiplied by the small parameter $\epsilon$.

---

1This result is true for much more general (but still spatially homogeneous) forms of the spring force than the one we have here.

2The language “acoustic” and “optical” bands is taken from Brillouin’s foundational text on wave propagation in periodic media [Bri53]. This book contains a detailed discussion of waves in linear diatomic lattices and in particular contains an excellent treatment of the dispersion relation.
The possible outcomes for singularly perturbed problems like this is pretty vast, of course. Many of the approaches for sussing out the consequences are either geometric or dynamical in nature. Our problem is nonlocal and as such it is not obvious to us how to use, say, geometric singular perturbation theory (as in [AGJ90] for instance) or fast-slow averaging (e.g. [BYB10]) to our setting. And so we turn to the functional analytic approach developed by Beale to prove the existence of solitary capillary-gravity waves in his staggering article [Bea91].

Here is what we discover:

**Theorem 1.** Suppose that $m_1 > m_2 > 0$. For wavespeeds $c$ sufficiently close to, but larger than, the speed of sound of the lattice, $c_{\text{sound}} := \sqrt{2k_s/(m_1 + m_2)}$, there exist traveling wave solutions of the diatomic FPUT problem which are the superposition of two pieces. One piece is a nonzero exponentially localized function that is a small perturbation of a $\text{sech}^2$ profile which, in turn, solves a KdV traveling wave equation. This whole localized piece has amplitude roughly proportional to $(c - c_{\text{sound}})$ and has wavelength roughly proportional to $(c - c_{\text{sound}})^{-1/2}$. The other piece is a periodic function, called a “ripple.” The frequency of the ripple is $O(1)$ when compared to $(c - c_{\text{sound}})$. Its amplitude is small beyond all orders of $(c - c_{\text{sound}})$.

As we shall see, the periodic part is fundamentally tied to the optical branch of the dispersion relation. Moreover we expect that the periodic part is exponentially small in $(c - c_{\text{sound}})$. Solutions of this type—a localized piece plus an extremely small oscillatory part—are sometimes called *nanopterons* [Boy90].

It is because the solutions we discover do not converge to zero at spatial infinity that we were cagey about our answer to the existence question earlier; our result raises as many questions as it answers. Chief of these is whether or not the ripple at infinity is genuine or merely a technical byproduct of our proof. After all, we do not provide lower bounds on its size, only upper bounds; perhaps the amplitude is zero! While we do not have the right sort of estimates at this time to answer this question either way we point out that Sun, in [Sun91], showed that the ripple for the capillary-gravity waves studied in [Bea91] was in fact non-zero. And so we conjecture that the same happens here, at least for almost all wave speeds.

This article is structured in the following manner.

- In the next section we nondimensionalize (0.1) and rewrite the resulting system in terms of the relative displacements.
- In Section 2 we make the traveling wave ansatz and get the traveling wave equations. We then diagonalize the resulting system using Fourier methods. It is during the diagonalization that the structure of the branches of the dispersion relation becomes apparent. Then we make a useful “long wave” rescaling. It is during this part that the singular nature of the problem comes into sight.
- In Section 3 we analyze the rescaled system in the limit where $c = c_{\text{sound}}$; we find that the problem in this case reduces to a single KdV traveling wave equation.

---

3 Or, equivalently, a heteroclinic connection between small amplitude periodic orbits.
In Section 4 we construct exact traveling wave solutions which are spatially periodic. These will ultimately be the ripples. A major difference between our results and the extant existence results for periodic traveling waves in polyatomic FPUT ([Qin15], [BP13]) is that we prove estimates on their size and frequency which are uniform in the speed $c$. This is done using a Crandall-Rabinowitz-Zeidler bifurcation analysis [CR71] [Zei86].

In Section 5 we make what we call “Beale’s ansatz.” That is, we assume the solution is the superposition of (a) the KdV solitary wave profile from Section 3, (b) a periodic solution from Section 4 with unknown amplitude and (c) a small, localized remainder. We then derive equations for the remainder and the amplitude of the periodic part. This derivation can be viewed as Liapunov-Schmidt decomposition, albeit a somewhat atypical one.

In Section 6 we state the main estimates we need and then, given those estimates, prove our main results using a modified contraction mapping argument. Specifically we prove Theorem 16 and Corollary 17, which are the technical versions of Theorem 1.

Sections 7, 8 and 9 contain the proof of the main estimates; these are the technical heart of the paper.

Finally Section 10 presents some comments on our results, avenues for further investigation and concluding remarks.

1. Nondimensionalization and the equations for relative displacements.

We can simplify (0.1) somewhat by putting $\bar{y}_j = \bar{x}_j - j l_s$. Then (0.1) is equivalent to

$$m_j \frac{d^2 \bar{x}_j}{dt^2} = -k_s \bar{r}_{j-1} - b_s \bar{r}_{j-1} + k_s \bar{r}_j + b_s \bar{r}_j^2$$

where $\bar{r}_j := \bar{x}_{j+1} - \bar{x}_j$. Note that the system is in equilibrium when $\bar{x}_j = 0$ for all $j$.

Next we nondimensionalize by taking $\bar{x}_j(\bar{t}) = a_1 x_j(a_2 \bar{t})$ where $a_1, a_2$ are nonzero constants. This converts (1.1) to

$$m_j a_2^2 \frac{d^2 x_j}{dt^2} = -k_s r_{j-1} - a_1 b_s r_{j-1} + k_s r_j + a_1 b_s r_j^2$$

where $r_j = x_{j+1} - x_j$.

Note that here $\bar{t} = a_2 \bar{t}$.

Selecting $a_1$ and $a_2$ such that $m_1 a_2^2 = k_s$ and $a_1 b_s = k$ yields

$$\ddot{x}_j = -r_{j-1} - r_{j-1}^2 + r_j + r_j^2 \quad \text{when } j \text{ is odd}$$

$$\frac{1}{w} \ddot{x}_j = -r_{j-1} - r_{j-1}^2 + r_j + r_j^2 \quad \text{when } j \text{ is even}.$$  

In the above,

$$w := \frac{m_1}{m_2} > 1$$

because $m_1 > m_2$.

It is both traditional and technically advantageous to express the equations of motion for lattices in terms of the relative displacements, $r_j$, instead of in the displacements from
equilibrium, $x_j$. We find that
\[
\dddot{r}_j = -(1 + w)(r_j + r_j^2) + w(r_{j+1} + r_{j+1}^2) + (r_{j-1} + r_{j-1}^2) \quad \text{when } j \text{ is odd}
\]
\[
\dddot{r}_j = -(1 + w)(r_j + r_j^2) + (r_{j+1} + r_{j+1}^2) + w(r_{j-1} + r_{j-1}^2) \quad \text{when } j \text{ is even}.
\]

2. Derivation of the traveling wave equations

We are interested in traveling wave solutions and so we make the ansatz
\[
r_j(t) = \begin{cases} 
p_1(j - ct) & \text{when } j \text{ is odd} \\
p_2(j - ct) & \text{when } j \text{ is even}. 
\end{cases}
\]

Here $c \in \mathbb{R}$ is the wave speed and $p_1, p_2 : \mathbb{R} \to \mathbb{R}$. Putting this into (1.3) gives us the following advance-delay-differential system of equations for $p_1$ and $p_2$:
\[
c^2 p_1'' = -(1 + w)(p_1 + p_1^2) + wS_1(p_2 + p_2^2) + S^{-1}(p_2 + p_2^2)
\]
\[
c^2 p_2'' = -(1 + w)(p_2 + p_2^2) + wS_1(p_1 + p_1^2) + S^{-1}(p_1 + p_1^2).
\]

Above, $S^d$ is the “shift by $d$” operator. Specifically:
\[S^d f(\cdot) := f(\cdot + d).\]

If we let
\[L := \begin{bmatrix} 1 + w & -(wS_1 + S^{-1}) \\ -(wS^{-1} + S^1) & 1 + w \end{bmatrix},\]
then we can compress (2.2) to
\[
c^2 \mathbf{p}'' + L(\mathbf{p} + \mathbf{p}^2) = 0.
\]

2.1. Diagonalization of the linear part. We can diagonalize (2.3) using Fourier analysis and the first step is to compute the action of $L$ on complex exponentials. We find that for any vector $\mathbf{v} \in \mathbb{R}^2$ and $k \in \mathbb{R}$ that
\[L[e^{ikx} \mathbf{v}] = [\tilde{L}(k) \mathbf{v}]e^{ikx}\]
where
\[
\tilde{L}(k) := \begin{bmatrix} 1 + w & -\tilde{\beta}(k) \\ -\tilde{\beta}(-k) & 1 + w \end{bmatrix} \quad \text{and} \quad \tilde{\beta}(k) := we^k + e^{-ik}.
\]

A routine calculation shows that the eigenvalues of $\tilde{L}(k)$ are given by
\[
\tilde{\lambda}_\pm(k) := 1 + w \pm \tilde{\varrho}(k) \quad \text{where} \quad \tilde{\varrho}(k) := \sqrt{(1 - w)^2 + 4w \cos^2(k)}.
\]

The following lemma contains many of the properties of $\tilde{\lambda}_\pm(k)$ we will need (the proof is in Section 9).

Lemma 2. The following hold for all $w > 1$.
\[
(i) \quad \tilde{\lambda}_-(0) = 0 \quad \text{and} \quad \tilde{\lambda}_+(0) = 2 + 2w.
\]

4Note the for 2-vectors $\mathbf{x}$ and $\mathbf{y}$ we use the notational convention that $\mathbf{x} \cdot \mathbf{y}$ is component-wise multiplication. Likewise $\mathbf{x}^2$ is component-wise squaring.
There exists $\tau_0 > 0$ such that $\tilde{\lambda}_\pm(z)$ are uniformly bounded complex analytic functions in the closed strip $\Sigma_{\tau_0} := \{ z \in \mathbb{C} : |\Im z| \leq \tau_0 \}$.

(iii) $\tilde{\lambda}_\pm(z)$ are even and $\tilde{\lambda}_\pm(z + \pi) = \tilde{\lambda}_\pm(z)$ for all $z \in \Sigma_{\tau_0}$.

(iv) For all $k \in \mathbb{R}$ we have
\begin{equation}
0 \leq \tilde{\lambda}_- (k) \leq 2 < 2w \leq \tilde{\lambda}_+ (k) \leq 2 + 2w.
\end{equation}

(v) For all $k \in \mathbb{R}$ we have
\begin{equation}
|\tilde{\lambda}_+ (k)| \leq 2 \quad \text{and} \quad |\tilde{\lambda}_- (k)| \leq 2c_w^2 |k|
\end{equation}
where
\begin{equation}
c_w := \sqrt{\frac{1}{2} \lambda''(0)} = \sqrt{\frac{2w}{1+w}} = \text{“the (nondimensionalized) speed of sound.”}
\end{equation}
Additionally $c_w > 1$.

(vi) There exists $c_- \in (0, 1)$ and $l_0 > 0$ such that for all $c \geq c_-$ there exists a unique nonnegative $k_c$ for which
\begin{equation}
c^2 k_c^2 - \tilde{\lambda}_+ (k_c) = 0.
\end{equation}
Moreover
\begin{equation}k_c \in [\sqrt{2w/c}, \sqrt{2 + 2w/c}]
\end{equation}
and
\begin{equation}2c^2 k_c - \tilde{\lambda}_+ (k_c) \geq l_0.
\end{equation}
Lastly, the map $c \mapsto k_c$ is $C^\infty$.

**Remark 1.** The eigenvalues $\tilde{\lambda}_\pm (k)$ are tied to the dispersion relation for (1.3). To be precise, we have plane wave solutions for the linearization of (1.3) at $r = 0$ of the form
\begin{equation}r_j(t) = \begin{cases} v_1 e^{i(kj - \omega t)} & \text{when } j \text{ is odd} \\ v_2 e^{i(kj - \omega t)} & \text{when } j \text{ is even} \end{cases}
\end{equation}
if and only if $\omega$ and $k$ satisfy the dispersion relation
\begin{equation}(\omega^2 - (1 + w))^2 - \tilde{\beta}(k)\tilde{\beta}(-k) = 0
\end{equation}
and $(v_1, v_2)^t$ is an appropriately chosen eigenvector of $\tilde{L}(k)$. (See, for instance, [Bri53].)

The set of such $\omega$ and $k$ which meet (2.10) has two connected components with $\omega \geq 0$. (It is obviously even in $\omega$.) These are
\begin{equation}\omega = \sqrt{\tilde{\lambda}_- (k)}, \quad \text{in which case we say } \omega \text{ is on the “acoustic” branch of (2.10),}
\end{equation}
\begin{equation}\text{and } \omega = \sqrt{\tilde{\lambda}_+ (k)}, \quad \text{in which case we say } \omega \text{ is on the “optical” branch.}
\end{equation}

In the monatomic problem, the dispersion relation has but one branch and is akin to $\omega^2 - \sin^2(k) = 0$, see [FP99]. Plotting $\tilde{\lambda}_-(k)$ and $\sin^2(k)$ will show that the two functions are

---

5 We extend $\tilde{\lambda}_\pm(k)$ and $\tilde{\theta}(k)$ to functions of $z = k + i \tau \in \mathbb{C}$ in a simple way by using the extension of cosine to complex inputs.
qualitatively much alike. The phase speed of the monatomic problem is maximum at \( k = 0 \); this maximum speed is called the speed of sound. The same is true for the phase speed of waves associated to the acoustic branch. Specifically, corollary to the second estimate in (2.6) is the fact that that the phase speed, \( \omega/k \), of plane waves associated to the acoustic branch is no bigger than \( c_w \).

The solitary waves for the monatomic problem have speeds which are strictly supersonic; the reason for this is discussed further below. In any case, the nonlinear waves move faster than the linear waves.\(^6\) But in the dimer problem we consider there are optical branch linear waves with all possible phase speeds, as can be seen by plotting \( \sqrt{\tilde{\lambda}_+ (k)} / k \). The point is this: if we search for a localized acoustic wave that travels with a supersonic speed \( c > c_w \) then there will necessarily be an optical branch linear wave whose phase is exactly \( c \). See Figure 1. Equating the solitary wave’s speed to the optical phase speed yields the relation \( c^2 k^2 - \lambda_+(k) = 0 \). As stated in Lemma 2, there is a unique nonnegative solution of this: \( k = k_c \). In a very rough sense, then, we expect the localized acoustic wave with speed \( c \) to excite a mode in the optical branch with wavenumber \( k_c \). Making this intuition rigorous is, of course, a substantial part of our analysis.

The inequalities in (2.5) imply \( \tilde{\lambda}_-(k) < \tilde{\lambda}_+(k) \) for all \( k \in \mathbb{R} \). Thus \( \tilde{L}(k) \) is diagonalizable for all \( k \). Towards this end, we compute that the eigenvectors of \( \tilde{L}(k) \) are scalar multiples of

\[
\begin{bmatrix}
\beta(k) \\
\bar{g}(k)
\end{bmatrix}
\text{ (for } \tilde{\lambda}_-(k) \text{)} \quad \text{and} \quad
\begin{bmatrix}
\bar{\beta}(k) \\
-\bar{g}(k)
\end{bmatrix}
\text{ (for } \tilde{\lambda}_+(k) \text{)}.
\]

\(^6\)This fact is crucial to the proof of the stability of the solitary waves in [FP02] [FP04a] [FP04b] and [HW13].
Then we have
\[
\tilde{\gamma}(k) := e^{-ik} + e^{ik} \tilde{\beta}(k) / \beta(k)
\]
and put
\[
\tilde{J}_2(k) := \begin{bmatrix} \tilde{\gamma}(k)\tilde{\beta}(k) & \tilde{\gamma}(k)\tilde{\beta}(k) \\ \tilde{\gamma}(k)\tilde{\beta}(k) & -\tilde{\gamma}(k)\tilde{\beta}(k) \end{bmatrix}.
\]
Its inverse is
\[
\tilde{J}_1(k) := \tilde{J}_2^{-1}(k) = \begin{bmatrix} (2\tilde{\gamma}(k)\tilde{\beta}(k))^{-1} & (2\tilde{\gamma}(k)\tilde{\beta}(k))^{-1} \\ (2\tilde{\gamma}(k)\tilde{\beta}(k))^{-1} & -(2\tilde{\gamma}(k)\tilde{\beta}(k))^{-1} \end{bmatrix}.
\]
Then we have
\[
\tilde{J}_1(k)\tilde{L}(k)\tilde{J}_2(k) = \tilde{\Lambda}(k) := \begin{bmatrix} \tilde{\lambda}_-(k) & 0 \\ 0 & \tilde{\lambda}_+(k) \end{bmatrix}.
\]

The reason we choose to normalize the eigenvectors with \(\tilde{\gamma}\) is obviously non-obvious. Here is what is special about \(\tilde{\gamma}\):
\[
(2.11) \quad \tilde{\gamma}(-k)\tilde{\beta}(-k) = \tilde{\gamma}(k)\tilde{\beta}(k).
\]
This property—easily checked—will imply a certain symmetry below, specifically in the proof of Lemma 4.

A short computation indicates that neither \(\tilde{\gamma}\) nor \(\tilde{\beta}\) vanish when \(k \in \mathbb{R}\). In fact, we have:

**Corollary 3.** If \(w > 1\) then there exists \(\tau_1 \in (0, \tau_0]\) such that \(\tilde{\gamma}(z), \tilde{\gamma}^{-1}(z), \tilde{\beta}(z)\) and \(\tilde{\beta}^{-1}(z)\) are uniformly bounded analytic functions for \(z \in \Sigma_{\tau_1}\). Moreover \(\tilde{J}_1(z)\) and \(\tilde{J}_2(z)\) are uniformly bounded matrix valued analytic functions for \(z \in \Sigma_{\tau_1}\).

We do not provide a proof, as it is more or less immediate from the definitions and Lemma 2. Note also that
\[
(2.12) \quad \tilde{J}_1(0) = \frac{1}{4(1+w)} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \quad \text{and} \quad \tilde{J}_2(0) = 2(1+w) \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}.
\]

Since \(\tilde{J}_1\) and \(\tilde{J}_2\) diagonalize \(\tilde{L}\), we can use Fourier multiplier operators to diagonalize \(L\). We use following normalizations and notations for the Fourier transform and its inverse:
\[
\hat{f}(k) := \mathfrak{F}[f](k) := \frac{1}{2\pi} \int_{\mathbb{R}} f(x)e^{-ikx}dx \quad \text{and} \quad \mathfrak{F}^{-1}[g](x) := \int_{\mathbb{R}} g(k)e^{ikx}dk.
\]
Likewise, we use the following normalizations and notations for the Fourier series of a \(2P\)-periodic function:
\[
\hat{f}(k) := \frac{1}{2P} \int_{-P}^{P} f(x)e^{-ik\pi x/P}dx \quad \text{and} \quad f(x) = \sum_{k \in \mathbb{Z}} \hat{f}(k)e^{ik\pi x/P}.
\]
We have used the same “hat” notation for the Fourier transform and the coefficients of the Fourier series; context will always make it clear which we mean.
Definition 1. Suppose that we have $\tilde{\mu} : \mathbb{R} \to \mathbb{C}$. The “Fourier multiplier with symbol $\tilde{\mu}$” is defined as follows.

(i) If $f : \mathbb{R} \to \mathbb{C}$ has a well-defined Fourier transform then

$$\mu f(x) := \int_{\mathbb{R}} e^{ikx} \tilde{\mu}(k) \hat{f}(k) dk.$$  

(ii) If $f : \mathbb{R} \to \mathbb{C}$ is $2P$-periodic then

$$\mu f(x) := \sum_{k \in \mathbb{Z}} e^{ik\pi x/P} \tilde{\mu}(k\pi/P) \hat{f}(k).$$  

(iii) If $f = f_1 + f_2$ where $f_1 : \mathbb{R} \to \mathbb{C}$ has a well-defined Fourier transform and $f_2 : \mathbb{R} \to \mathbb{C}$ is $2P$-periodic then we have $\mu f = \mu f_1 + \mu f_2$ where $\mu f_1$ is computed with (2.13) and $\mu f_2$ is computed with (2.14).

Remark 2. An alternate way to express (2.14) goes as follows. Since $f(x)$ is $2P$-periodic we know $f(x) = \phi(\omega x)$ for some $2\pi$-periodic function $\phi(y)$ and $\omega = \pi/P$. In this case $\mu f(x) = (\mu^\omega \phi)(\omega x)$ where $\mu^\omega$ is a Fourier multiplier with symbol $\tilde{\mu}^\omega(k) = \tilde{\mu}(\omega k)$. The nice thing here is that

$$\mu^\omega \phi(y) = \sum_{k \in \mathbb{Z}} e^{iky} \tilde{\mu}^\omega(k) \hat{\phi}(k),$$

a slightly less complicated formula than (2.14). Note also that if we put a $2P$-periodic function into the Fourier transform integral $\mathcal{F}$ then we can interpret the output as a distribution. Specifically, it will be a superposition of delta-functions situated on $(\pi/P)\mathbb{Z} \subset \mathbb{R}$. In this case we can apply the formula (2.13). The outcome of this coincides exactly with (2.14). In this way we can see that the formula in Part (iii) is the “correct” way to apply Fourier multipliers to sums of decaying and periodic functions.

So let $\lambda_{\pm}, \rho, \beta, \gamma, \Lambda$ and $J_n$ be the Fourier multiplier operators with symbols $\tilde{\lambda}_{\pm}, \tilde{\rho}, \tilde{\beta}, \tilde{\gamma}, \tilde{\Lambda}$ and $\tilde{J}_n$, respectively. Put $p := J_2 h$. If $p$ solves (2.3) then we find that $h$ solves

$$c^2 h'' + \Lambda h + \Lambda B(h, h) = 0$$

with

$$B(h, \dot{h}) := \left( \begin{array}{c} b_1(h, \dot{h}) \\ b_2(h, \dot{h}) \end{array} \right) := J_1(J_2 h, J_2 \dot{h}).$$

Written out component-wise this is

$$c^2 h_1'' + \lambda_- h_1 + \lambda_- b_1(h, h) = 0 \quad \text{and} \quad c^2 h_2'' + \lambda_+ h_2 + \lambda_+ b_2(h, h) = 0.$$

Remark 3. Since $\lambda_-$ is associated to the acoustic branch of the dispersion relation and $\lambda_+$ to the optical branch, we informally think of $h_1$ as the “acoustic part” of the solution and $h_2$ as the “optical part.” What we shall see down the line is that the dominant part of $h_1$ is a $\text{sech}^2$ traveling wave, whereas the periodic solutions will be largest in $h_2$.  

2.2. The Friesecke-Pego cancelation. Applying $\mathfrak{F}$ to the first equation in (2.16) gives

$$\left(-c^2k^2 + \tilde{\lambda}_-(k)\right) \hat{h}_1 + \tilde{\lambda}_-(k)b_1(h, h) = 0.$$  

Since $\tilde{\lambda}_-(0) = 0$ and is even, it is roughly quadratic in $k$ near the origin. Obviously so is $k^2$. Which indicates that we can cancel a $k^2$ out of the above if we chose. We do not do precisely this, but instead employ a similar approach inspired by the proof of the existence of low energy solitary waves for monotomic FPU in [FP99].

We know that $\tilde{\lambda}_-(0) = 0$. We also know from (2.6) that $|\tilde{\lambda}_-'(k)| \leq 2c_w^2|k|$. And so the FTOC$^7$ implies:

$$c^2k^2 - \tilde{\lambda}_-(k) > 0 \quad \text{for all } k \neq 0 \text{ provided } c^2 \geq c_w^2.$$  

This allows us to divide through in (2.17), not by $k^2$, but rather by $-c^2k^2 + \tilde{\lambda}_-(k)$.

So put

$$\tilde{\varpi}_c(k) := -\frac{\tilde{\lambda}_-(k)}{c^2k^2 - \tilde{\lambda}_-(k)}.$$  

This function has a removable singularity at $k = 0$ when $c^2 \geq c_w^2$ and no other singularities for $k \in \mathbb{R}$. Then (2.17) is equivalent to $\hat{h}_1 + \tilde{\varpi}_c(k)b_1(h, h) = 0$.

Let $\varpi_c f$ be the Fourier multiplier operator with symbol $\tilde{\varpi}_c$. The above reasoning shows we can rewrite (2.16) as

$$h_1 + \varpi_c b_1(h, h) = 0 \quad \text{and} \quad c^2h_2'' + \lambda_+h_2 + \lambda_+b_2(h, h) = 0$$

or alternately as:

$$\mathcal{H}_c(h) := \begin{bmatrix} 1 & 0 \\ 0 & c^2\partial_x^2 + \lambda_+ \end{bmatrix} h + \begin{bmatrix} \varpi_c & 0 \\ 0 & \lambda_+ \end{bmatrix} B(h, h) = 0.$$  

Remark 4. We will henceforth require $c^2 > c_w^2$ so that our map $\varpi_c$ is well-defined; this is the technical reason why we look for (and why the authors of [FP99] looked for) nonlinear waves which are supersonic. Unraveling the scalings that lead to (1.3) from (0.1) shows that the traveling wave solutions under investigation here will, in the physical coordinates, travel with a speed faster than $c_{\text{sound}} := \sqrt{k_{s} / \bar{m}}$, where $\bar{m}$ is the average of the two masses.

We have the following nice symmetry result for $\mathcal{H}_c$.

Lemma 4. If $h_1$ is even and $h_2$ is odd, the first and second components of $\mathcal{H}_c(h)$ are, respectively, even and odd.

Proof. For a function $f(y)$ let $Rf(y) = f(-y)$. If $f$ is even then $f = Rf$. If $f$ is odd then $f = -Rf$. If $\mu$ is a Fourier multiplier with symbol $\tilde{\mu}$ then

$$R(\mu f)(x) = (R\mu)Rf(x).$$

By $R\mu$ we mean the Fourier multiplier with symbol $R\tilde{\mu}(k) = \tilde{\mu}(-k)$.

$^7$The Fundamental Theorem of Calculus, of course
If the symbol $\mu$ is even then this implies $R(\mu f) = \mu(Rf)$. This in turn implies that such a $\mu$ will map even functions to even functions and odd functions to odd functions. Thus $\lambda_\pm$, $\partial_x^2$ and $\varpi_\pm$ all “preserve parity.”

Informally, we say $h \in E \times O$ if $h_1$ is even and $h_2$ is odd. The preceding comments imply that we will have our result if we can show that $\tilde{B}(h, h)$ maps $E \times O$ to itself since the remaining parts of $\mathcal{H}_c$ will not flip an $E$ to an $O$ or vice versa. Note that $h \in E \times O$ if and only if $Rh = I_1h$ where $I_1 = \text{diag}(1, -1)$. Thus our goal is to show that if $Rh = I_1h$ then $RB(h, h) = I_1B(h, h)$.

So suppose that $Rh = I_1h$. Using (2.20) we have $RB(h, h) = (RJ_1)R[(J_2h)^2]$. It is easy to see that $R(fg) = RfRg$ and so the above gives $RB(h, h) = (RJ_1)[(R(J_2h))^2]$. Then we use (2.20) again to get $RB(h, h) = (RJ_1)[((RJ_2)(Rh))^2]$. Since $Rh = I_1h$ we have $RB(h, h) = (RJ_1)[((RJ_2)(I_1h))^2]$. Then associativity gives:

$$RB(h, h) = (RJ_1)[((RJ_2I_1h)^2].$$

The multiplier for $RJ_2$ is, using (2.20),

$$R\tilde{J}_2(k) = \tilde{J}_2(-k) = \begin{bmatrix} \tilde{\gamma}(-k)\tilde{\beta}(-k) & \tilde{\gamma}(-k)\tilde{\beta}(-k) \\ \tilde{\gamma}(-k)\tilde{\beta}(-k) & -\tilde{\gamma}(-k)\tilde{\beta}(-k) \end{bmatrix}. $$

Now we use the special property of $\tilde{\gamma}$ in (2.11) to convert this to:

$$R\tilde{J}_2(k) = \begin{bmatrix} \tilde{\gamma}(k)\tilde{\beta}(k) & \tilde{\gamma}(k)\tilde{\beta}(k) \\ \tilde{\gamma}(k)\tilde{\beta}(k) & -\tilde{\gamma}(k)\tilde{\beta}(k) \end{bmatrix}. $$

If we let $I_2 := \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ then the above relation implies, after a short calculation, that $R\tilde{J}_2 = I_2\tilde{J}_2 I_1$. Since $\tilde{J}_1 = \tilde{J}_2^{-1}$, $I_1^{-1} = I_1$ and $I_2^{-1} = I_2$, this gives. $R\tilde{J}_1 = I_1\tilde{J}_1 I_2$.

Using these relations in (2.21) gives us $RB(h, h) = I_1J_1I_2[(I_2J_2I_2^2)h^2]$. Since $I_2^2$ is the identity this is $RB(h, h) = I_1J_1I_2[(I_2J_2h)^2]$. Also, it is easy to check that $(I_2f)^2 = I_2(f^2)$. Thus we have $RB(h, h) = I_1J_1I_2[(J_2h)^2]$. Since $I_2^2$ is the identity this is $RB(h, h) = I_1J_1[(J_2h)^2] = I_1B(h, h)$. This was our goal and so we are done.

In light of this result, we restrict our attention henceforth to looking for solutions which are even in the first component and odd in the second.

2.3. Long wave scaling. Now make the long wave scaling (inspired by the classical multiscale derivation of the Korteweg-de Vries equation from monotonic FPU in [Kru74])

$$h_1(x) := \epsilon^2\theta_1(\epsilon x), \quad h_2 := \epsilon^2\theta_2(\epsilon x) \quad \text{and} \quad \epsilon^2 = c_w^2 + \epsilon^2$$

where $0 < \epsilon \ll 1$.

**Remark 5.** Note that if $\mu$ is a Fourier multiplier operator with symbol $\tilde{\mu}(k)$ and if $f(x) = \phi(\omega x)$ then $\mu f(x) = (\mu^\omega \phi)(\epsilon x)$ where $\mu^\omega$ is a Fourier multiplier with symbol $\tilde{\mu}^\omega(k) := \tilde{\mu}(\omega k)$.

After the scaling, (2.19) becomes

$$\theta_1 + \varpi^2 b_1(\theta, \theta) = 0 \quad \text{and} \quad \epsilon^2(c_w^2 + \epsilon^2)\theta_2^\epsilon + \lambda_+ \theta_2 + \epsilon^2 \lambda_+ b_2(\theta, \theta) = 0$$
with \( \theta := \begin{pmatrix} \theta_1 \\ \theta_2 \end{pmatrix} \),

\[
\tilde{\varpi}^\epsilon(K) := \epsilon^2 \sqrt{c_w^2 + \epsilon^2}(\epsilon K) = \frac{\epsilon^2 \tilde{\lambda}_-(\epsilon K)}{(c_w^2 + \epsilon^2)\epsilon^2 K^2 - \tilde{\lambda}_-(\epsilon K)},
\]

(2.23)

\[
\tilde{\lambda}_\pm^\epsilon(K) := \tilde{\lambda}_\pm(\epsilon K),
\]

(2.24)

\[
\tilde{J}_j^\epsilon(K) := \tilde{J}_j(\epsilon K)
\]

and

(2.26)

\[
B^\epsilon(\theta^\epsilon, \dot{\theta}^\epsilon) := \begin{pmatrix} b_1^\epsilon(\theta^\epsilon, \dot{\theta}^\epsilon) \\ b_2^\epsilon(\theta^\epsilon, \dot{\theta}^\epsilon) \end{pmatrix} := J_1^\epsilon \left[ J_2^\epsilon \theta^\epsilon \right].
\]

Of course \( \varpi^\epsilon, \lambda_\pm^\epsilon \) and \( J_n^\epsilon \) are Fourier multiplier operators with the symbols taken in the obvious way. Note that since we assume the \( \epsilon \in (0, 1) \), the scaling implies, via Lemma 2 and Corollary 3, that \( \lambda_\pm^\epsilon(Z) \) and \( \tilde{J}_n^\epsilon(Z) \) are analytic for \( |\Re(Z)| \leq \tau_1 \leq \tau_1/\epsilon \).

**Remark 6.** The equation for \( \theta_2 \) (which is the part associated to the optical branch) is classically singular when \( \epsilon \sim 0 \) because of the term

\[ \epsilon^2 (c_w^2 + \epsilon^2)\theta_2''. \]

Had we not performed the Friesecke-Pego cancelation earlier, the \( \theta_1 \) equation would have a similarly singular term. But the cancelation desingularizes that equation as we shall demonstrate below. Of course this why they made that cancelation in their work \([FP99]\) and why we do so here. But because \( \tilde{\lambda}_+(0) \neq 0 \) there is no chance to make a similar cancelation in the second component.

We can write (2.22) as:

\[
\Theta^\epsilon(\theta) := \begin{pmatrix} 1 & 0 \\ 0 & \epsilon^2 (c_w^2 + \epsilon^2)\partial_X^2 + \lambda_\pm^\epsilon \end{pmatrix} \theta + \begin{pmatrix} \varpi^\epsilon & 0 \\ 0 & \epsilon^2 \lambda_\pm^\epsilon \end{pmatrix} B^\epsilon(\theta, \dot{\theta}) = 0.
\]

(2.27)

The long wave scaling does not effect the symmetry mapping properties that \( \mathcal{H}_\epsilon \) had. To wit:

**Lemma 5.** If \( \theta_1 \) is even and \( \theta_2 \) is odd, the first and second components of \( \Theta^\epsilon(h) \) are, respectively, even and odd.

3. The Formal Long Wave Limit

In this section we naively set \( \epsilon = 0 \) in (2.22). This is mostly routine. For instance, given the definitions in (2.24) and (2.25), we set \( \lambda_+^0(K) := \tilde{\lambda}_+(0) \) and \( \tilde{J}_j^0(K) := \tilde{J}_j(0) \). So we define, (using (2.12)):

\[ \lambda_+^0 := 2 + 2w, \quad J_1^0 := \frac{1}{4(1 + w)} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad \text{and} \quad J_2^0 := 2(1 + w) \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}. \]
This in turn leads to the definition
\[ B^0(\theta, \dot{\theta}) := \left( \begin{array}{c} b_1^0(\theta, \dot{\theta}) \\ b_2^0(\theta, \dot{\theta}) \end{array} \right) := J_1^0 \left[ J_2^0 \theta J_2^0 \dot{\theta} \right] = 2(1 + w) \left( \frac{\theta_1 \dot{\theta}_1 + \theta_2 \dot{\theta}_2}{\theta_1 \dot{\theta}_2 + \theta_2 \dot{\theta}_1} \right). \]

Blindly setting \( \epsilon = 0 \) in \( \tilde{\omega}(K) \) will not work; a “0/0” situation occurs. Computing the Maclaurin expansion of \( \tilde{\lambda}_+(k) \) gives
\[ \tilde{\lambda}_-(k) = c_w^2 k^2 - \alpha_w k^4 + \cdots \]
where
\[ \alpha_w := \frac{c_w^2}{3} \frac{1 - w + w^2}{(1 + w)^2} > 0. \]
Thus we have
\[ \tilde{\omega}^\epsilon(K) = -\frac{\epsilon^2 \tilde{\lambda}_-(\epsilon K)}{(c_w^2 + \epsilon^2)\epsilon^2 K^2} = -\frac{\epsilon^2 c_w^2 K^2 + \mathcal{O}_f(\epsilon^6)}{(c_w^2 + \epsilon^2)\epsilon^2 K^2 - \epsilon^2 c_w^2 K^2 + \alpha_w \epsilon^4 K^2 + \mathcal{O}_f(\epsilon^6)} \]
By “\( \mathcal{O}_f(\epsilon^n) \)” we mean terms which are formally of order \( \epsilon^n \).

After some cancelations this becomes
\[ \tilde{\omega}^\epsilon(K) = -\frac{\epsilon^4 c_w^2 K^2 + \mathcal{O}_f(\epsilon^6)}{\epsilon^4 K^2 + \alpha_w \epsilon^4 K^2 + \mathcal{O}_f(\epsilon^6)} = -\frac{c_w^2 K^2 + \mathcal{O}_f(\epsilon^2)}{K^2 + \alpha_w K^4 + \mathcal{O}_f(\epsilon^2)}. \]
Now we set \( \epsilon = 0 \) to get
\[
\tilde{\omega}^0(K) := -\frac{c_w^2}{1 + \alpha_w K^2} \quad \text{and} \quad \omega^0 := -c_w^2 \left( 1 - \alpha_w \partial_X^2 \right)^{-1}.
\]

**Remark 7.** We will give precise estimates on the operator norms of \( \omega^\epsilon - \omega^0 \), \( \lambda^\epsilon - \lambda^0 \) and so on in Section 7.

With all of this, if we put \( \epsilon = 0 \) in (2.22) we arrive at:
\[ \theta_1 - \frac{4w}{1 - \alpha_w \partial_X^2} \left[ \theta_1^2 + \theta_2^2 \right] = 0 \quad \text{and} \quad (2 + 2w)\theta_2 = 0. \]
To solve this we take \( \theta_2 = 0 \) and \( \theta_1 \) a solution of
\[ \theta_1 - \frac{4w}{1 - \alpha_w \partial_X^2} \left[ \theta_1^2 \right] = 0. \]
Applying \( 1 - \alpha_w \partial_X^2 \) to the above results in
\[
\alpha_w \theta_1'' - \theta_1 + 4w \theta_1^2 = 0.
\]
This is a rescaling of the nonlinear differential equation whose solutions give the profile for the KdV solitary waves. It has an explicit solution given by
\[
\theta_1(X) = \sigma(X) := \sigma_0 \text{sech}^2(2q_0 X) \quad \text{where} \quad \sigma_0 := \frac{3}{8w} \quad \text{and} \quad q_0 := \frac{1}{2\sqrt{\alpha_w}}.
\]
Note that if we put \( \sigma := (\sigma, 0)^t \) then we have shown:
\[
\sigma + \omega^0 b_1^0(\sigma, \sigma) = 0.
\]
Remark 8. Observe that in the limit \( \epsilon \to 0^+ \) the part of the solution associated to optical branch, \( \theta_2 \), plays no role. All the action is happening for the acoustic part \( \theta_1 \).

Remark 9. In [GMWZ14] the authors use homogenization theory to show that solutions of (1.3) with initial data of the form 

\[
\begin{align*}
    r(j,0) &= \epsilon^2 R(\epsilon j) \\
    \dot{x}(j,0) &= \epsilon^2 V(\epsilon j)
\end{align*}
\]

are well-approximated over long times by a pair of solutions of KdV. Specifically they show that

\[
    r(j,t) = \epsilon^2 U + \mathcal{O}(\epsilon^3) \quad \text{for all } |t| \leq C\epsilon^{-3}
\]

where \( U \) solve the KdV equations

\[
\pm \partial_T U + \alpha_w \partial_X^3 U + 4w \partial_X(U^2) = 0.
\]

Making a traveling wave ansatz for these of the form 

\[
    U(X,T) = \theta(X \mp T)
\]

results in (3.2); the coefficients match exactly. Which is to say the results here are consistent with those in [GMWZ14].

4. Periodic solutions

In this section we prove the existence of spatially periodic solutions of (2.22). To this end, we first compute the linearization of that equation about \( \theta(X) = 0 \) to get

\[
    \theta_1 = 0 \quad \text{and} \quad \epsilon^2(c_w^2 + \epsilon^2)\theta_2' + \lambda_+ \theta_2 = 0.
\]

We are looking for solutions where \( \theta_2 \) is odd and periodic. Thus we can take \( \theta_2(X) = \sin(K\epsilon X) \) for some \( K \epsilon \in \mathbb{R} \). Inserting this into the second equation above, and recalling that \( \lambda_+ \) is a Fourier multiplier operator with symbol \( \tilde{\lambda}_+(\epsilon K) \), gives

\[
    \epsilon^2(c_w^2 + \epsilon^2)K^2 \epsilon - \tilde{\lambda}_+(\epsilon K) = 0.
\]

If we put \( c = c_\epsilon := \sqrt{c_w^2 + \epsilon^2} \) and

\[
    K_\epsilon := k_{c_\epsilon}/\epsilon,
\]

this last equation is exactly (2.7). Which is to say, by virtue of Part (vi) of Lemma 2, that \( K_\epsilon \) is its unique nonnegative solution.

Thus we have odd periodic solutions of the the linearization of (2.22) of the form

\[
    \theta(X) = \nu_\epsilon(X) := \sin(K_\epsilon X)j.
\]

We can extend the existence of periodic solutions for the linear problem to the full nonlinear problem (2.22) by means of the technique of “bifurcation from a simple eigenvalue,” developed by Crandall & Rabinowitz in [CR71] and Zeidler in [Zei95]. Here is what we find:

Theorem 6. For all \( w > 1 \) there exist \( \epsilon_0 > 0 \), \( a_0 > 0 \) and \( 0 < C_1 < C_2 \) such the following holds for all for \( \epsilon \in (0,\epsilon_0) \). There exist maps

\[
\begin{align*}
    K_\epsilon^a : [-a_0,a_0] &\longrightarrow \mathbb{R} \\
    \psi_{\epsilon,1}^a : [-a_0,a_0] &\longrightarrow C_\per^\infty \cap \{\text{even functions}\} \\
    \psi_{\epsilon,2}^a : [-a_0,a_0] &\longrightarrow C_\per^\infty \cap \{\text{odd functions}\}
\end{align*}
\]

with the following properties.
(i) **Putting**

\[ \theta(X) = a \varphi^0(X) := a \begin{pmatrix} 0 \\ \sin(K^a X) \end{pmatrix} + a \begin{pmatrix} \psi^a_{e,1}(K^a X) \\ \psi^a_{e,1} \end{pmatrix} =: a \nu(K^a X) + \psi^a(K^a X) \]

solves \((2.22)\) for all \(|a| \leq a_0\).

(ii) \(K^a = K\) where \(K\) is the unique positive solution of

\[
\tilde{\xi} \sqrt{c^2 + \epsilon^2}(\epsilon K) := -\epsilon^2(c_w^2 + \epsilon^2)K^2 + \tilde{\lambda}_+ (\epsilon K) = 0.
\]

Moreover \(K = O(1/\epsilon)\) in the sense that

\[ C_1/\epsilon < K < C_2/\epsilon \quad \text{for all} \quad \epsilon \in (0, \epsilon_0). \]

(iii) \(\psi^0_{e,1} = \psi^0_{e,2} = 0\).

(iv) \(\int_{-\pi}^{\pi} \psi^a_{e,2}(y) \sin(y) \, dy = 0\) for all \(|a| \leq a_0\).

(v) For all \(r \geq 0\), there exists \(C_r > 0\) such that for all \(|a|, |\dot{a}| \leq a_0\) we have

\[
|\epsilon K^a| + \|\psi^a\|_{C_{\text{per}} \times C_{\text{per}}} \leq C_r
\]

and

\[
|K^a - K^0| + \|\psi^a - \psi^0\|_{C_{\text{per}} \times C_{\text{per}}} \leq C_r |a - \dot{a}|
\]

The remainder of Section 4 is dedicated to the proof of this theorem.

4.1. **Frequency freezing.** We begin by making the additional scaling

\[
\phi(Y) := \phi(\omega X) \quad \text{with} \quad \phi := \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}, \quad \omega \in \mathbb{R},
\]

where \(\phi(Y)\) is \(2\pi\)-periodic. By Remark 5, our system \((2.27)\) becomes

\[
\Phi^a(\phi, \omega) := \begin{pmatrix} 1 & 0 \\ 0 & \epsilon^2 \omega^2(c_w^2 + \epsilon^2)Y + \lambda^a_\omega \end{pmatrix} \phi + \begin{pmatrix} \overline{\nu}^a \omega & 0 \\ 0 & \epsilon^2 \lambda^a_\omega \end{pmatrix} B^a(\phi, \phi) = 0.
\]

where \(\overline{\nu}^a \omega\) is the multiplier with symbol

\[
\overline{\nu}^a \omega(K) := \overline{\nu}^a(\omega K),
\]

and the multipliers \(\lambda^a_\omega\) and \(B^a\) conform to their prior definitions.

Since \(B^a\) is quadratic in \(\phi\), it is easy to see that

\[
D_\phi \Phi^a(0, \omega) = \begin{pmatrix} 1 & 0 \\ 0 & \epsilon^2 \omega^2(c_w^2 + \epsilon^2) \end{pmatrix}
\]

When \(\omega = K\), one may show that zero is a simple eigenvalue of \(D_\phi \Phi^a(0, K)\) when the operator is restricted to a suitable function space; this is essentially just the calculation carried out at the start of this section. Consequently, the classical bifurcation results in \([\text{CR71}]\) and \([\text{Zei95}]\) can be used to show that there exists a nontrivial family of solutions to \(\Phi^a(\phi, \omega) = 0\) branching out of \((0, K^a)\). Unfortunately, those classical results do not provide, in an easy way, estimates on the solution which are uniform in \(\epsilon\). And so, while our strategy is modeled on the proofs of the results in \([\text{CR71}]\) and \([\text{Zei95}]\), we carry out the proof from
Conversion to a fixed-point problem. Let $$\mathcal{Y} = (H^2_{\text{per}} \cap \{\text{even functions}\}) \times (H^2_{\text{per}} \cap \{\text{odd functions}\})$$, where $$H^r_{\text{per}}$$ is the Sobolev space of 2π-periodic functions $$\phi$$ such that

$$\|\phi\|_{H^r_{\text{per}}} := \left(\sum_{k \in \mathbb{Z}} (1 + k^2)^r |\hat{\phi}(k)|^2\right)^{1/2} < \infty.$$ 

With $$\nu(Y) := \sin(Y)j$$, we have the direct sum decomposition $$\mathcal{Y} = N \oplus Z$$, where $$Z \subseteq \mathcal{Y}$$ is the orthogonal complement of $$N := \text{span}(\{\nu\})$$ in the standard $$H^2_{\text{per}} \times H^2_{\text{per}}$$ inner product, i.e.,

$$\langle \phi, \psi \rangle_{H^2_{\text{per}} \times H^2_{\text{per}}} := \langle \phi_1, \psi_1 \rangle_{H^2_{\text{per}}} + \langle \phi_2, \psi_2 \rangle_{H^2_{\text{per}}} \quad \text{with} \quad \langle \phi, \psi \rangle_{H^2_{\text{per}}} := \sum_{k \in \mathbb{Z}} (1 + k^2)^2 \hat{\phi}(k) \overline{\hat{\psi}(k)}.$$ 

We may then write any $$\phi \in \mathcal{Y}$$ as

$$\phi = a\nu + a\psi \quad \text{for some} \quad a \in \mathbb{R}, \; \psi \in Z.$$ 

Observe that if $$\psi \in Z$$, then $$\widehat{\psi}(\pm 1) \cdot j = 0$$. Set

$$\mathcal{X} = Z \times \mathbb{R}.$$ 

Since the trivial solution $$\phi = 0$$ already solves (4.6) for any choice of $$\omega$$, we will assume $$a \neq 0$$. After factoring and dividing by $$a$$, the problem

$$\Phi_\epsilon(\phi, K_\epsilon + t) = \Phi_\epsilon(a\nu + a\psi, K_\epsilon + t) = 0$$ 

becomes

$$\psi_1 + a\omega\epsilon(K_\epsilon + t)b_1^{\epsilon(K_\epsilon + t)}(\nu + \psi, \nu + \psi) = 0$$ 

and

$$\epsilon^2(K_\epsilon + t)^2(c^2_\epsilon + \epsilon^2)\partial^2_X + \lambda^{\epsilon(K_\epsilon + t)}_+(\sin(Y) + \psi_2) + a\epsilon^2\lambda^{\epsilon(K_\epsilon + t)}_+b_2^{\epsilon(K_\epsilon + t)}(\nu + \psi, \nu + \psi) = 0.$$ 

Let $$\Pi_1$$ be the Fourier multiplier with symbol

$$\tilde{\Pi}_1 := \begin{cases} 1, & |k| = 1 \\ 0, & |k| \neq 1 \end{cases}$$

and set $$\Pi_2 = 1 - \Pi_1$$. Then (4.9) and (4.10) are equivalent to

$$\psi_1 + a\omega\epsilon(K_\epsilon + t)b_1^{\epsilon(K_\epsilon + t)}(\nu + \psi, \nu + \psi) = 0,$$

$$\epsilon^2(K_\epsilon + t)^2(c^2_\epsilon + \epsilon^2)\partial^2_X + \lambda^{\epsilon(K_\epsilon + t)}_+(\sin(Y) + a\Pi_1\lambda^{\epsilon(K_\epsilon + t)}_+b_2^{\epsilon(K_\epsilon + t)}(\nu + \psi, \nu + \psi) = 0,$$

and

$$\epsilon^2(K_\epsilon + t)^2(c^2_\epsilon + \epsilon^2)\partial^2_X + \lambda^{\epsilon(K_\epsilon + t)}_+\psi_2 + a\epsilon^2\Pi_2\lambda^{\epsilon(K_\epsilon + t)}_+b_2^{\epsilon(K_\epsilon + t)}(\nu + \psi, \nu + \psi) = 0.$$ 

Condition (4.11) immediately gives a fixed-point equation for $$\psi_1$$, and we see that (4.12) holds if and only if the Fourier transform of its left side evaluated at $$k = \pm 1$$ is zero. Because
\( b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi) \) is odd by (the proof of) Lemma 4 we need only consider this Fourier transform at \( k = 1 \). With
\[
\tilde{\xi} \sqrt{\epsilon_{w}^{2} + \epsilon^{2}}(k) = -(\epsilon_{w}^{2} + \epsilon^{2})(ek)^{2} + \tilde{\lambda}_{+}(ek)
\]
as in (4.2) and \( c_{\epsilon} := \sqrt{\epsilon_{w}^{2} + \epsilon^{2}} \), set
\[
\epsilon, t = \tilde{\xi}_{c_{\epsilon}}(\epsilon(K_{c} + t)k)
\]
so that (4.12) is equivalent to
\[
\frac{1}{2\epsilon} \tilde{\xi}_{c_{\epsilon}}(1) + a\epsilon \tilde{\xi}_{c_{\epsilon}}(\epsilon(K_{c} + t)) \left[ \Pi_{1} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi) \right] (1) = 0.
\]
Taylor’s theorem tells us that
\[
\tilde{\xi}_{c_{\epsilon}}(1) = \tilde{\xi}_{c_{\epsilon}}(\epsilon K_{c} + \epsilon t) = \tilde{\xi}_{c_{\epsilon}}(\epsilon K_{c})(\epsilon t) + R_{c}(\epsilon t)(\epsilon t)^{2},
\]
and Part (vi) of Lemma 2 provides a number \( |\epsilon| \leq \epsilon_{0} \) such that
\[
|\tilde{\xi}_{c_{\epsilon}}(\epsilon K_{c})| \geq l_{0}
\]
for all \( \epsilon \) sufficiently close to zero. So, we may rewrite (4.15) as
\[
t = -\frac{\epsilon}{\xi_{c_{\epsilon}}(\epsilon K_{c})} R_{c}(\epsilon t) t^{2} - \frac{2i\epsilon a}{\xi_{c_{\epsilon}}(\epsilon K_{c})} \tilde{\xi}_{c_{\epsilon}}(\epsilon K_{c}) \left[ \Pi_{1} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi) \right] (1)
\]
Finally, we will show that \( \tilde{\xi}_{c_{\epsilon}}(k) \neq 0 \) for \( k \neq \pm 1 \), which means that the multiplier \( (\tilde{\xi}_{c_{\epsilon}})^{-1} \) with symbol \( (\tilde{\xi}_{c_{\epsilon}})^{-1} \) is well-defined on the range of \( \Pi_{2} \) for suitably small \( \epsilon \) and \( t \). Then (4.13) becomes
\[
\psi_{2} = -a\epsilon^{2} (\xi_{c_{\epsilon}})^{-1} \Pi_{2} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi).
\]
We have arrived at our ultimate fixed-point problem. Set \( \Psi_{\epsilon} := (\Psi_{\epsilon,1}, \Psi_{\epsilon,2}, \Psi_{\epsilon,3}) \) with
\[
\Psi_{\epsilon,1}(\psi, t, a) := -a\epsilon^{2}(\xi_{c_{\epsilon}})^{-1} \Pi_{2} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi)
\]
\[
\Psi_{\epsilon,2}(\psi, t, a) := -a\epsilon^{2}(\xi_{c_{\epsilon}})^{-1} \Pi_{2} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi)
\]
\[
\Psi_{\epsilon,3}(\psi, t, a) := -\frac{\epsilon}{\xi_{c_{\epsilon}}(\epsilon K_{c})} R_{c}(\epsilon t) t^{2} - \frac{2i\epsilon a}{\xi_{c_{\epsilon}}(\epsilon K_{c})} \tilde{\xi}_{c_{\epsilon}}(\epsilon K_{c}) \left[ \Pi_{1} \lambda_{+}^{(K_{c}+t)} b_{2}^{(K_{c}+t)}(\nu + \psi, \nu + \psi) \right] (1)
\]
We will solve this problem by applying the following lemma, whose proof is given in Section 4.4, to the map \( \Psi_{\epsilon} \) for \( \epsilon \) sufficiently small.

**Lemma 7.** Let \( X \) be a Banach space and let \( B(r) = \{ x \in X : \| x \| \leq r \} \). For \( 0 < \epsilon < \epsilon_{0} \) let \( F_{\epsilon} : X \times \mathbb{R} \rightarrow X \) be maps with the property that for some \( C_{1}, a_{1}, r_{1} > 0 \), if \( x, y \in B(r_{1}) \) and \( |a| \leq a_{1} \), then
\[
\sup_{0 < \epsilon < \epsilon_{0}} \| F_{\epsilon}(x, a) \| \leq C_{1} (|a| + |a| \|x\| + \|x\|^{2})
\]
Then there exist \( a_0 \in (0, a_1], r_0 \in (0, r_1] \) such that for each \( 0 < \epsilon < \epsilon_0 \) and \( |a| \leq a_0 \), there is a unique \( x_\epsilon^a \in \mathcal{B}(r_0) \) such that \( F_\epsilon(x_\epsilon^a, a) = x_\epsilon^a \).

Suppose as well that the maps \( F_\epsilon(\cdot, a) \) are Lipschitz on \( \mathcal{B}(r_0) \) uniformly in \( a \) and \( \epsilon \), i.e., there is \( L_1 > 0 \) such that

\[
(4.20) \quad \sup_{0 < \epsilon < \epsilon_0} \sup_{0 < |x| < r_0} \| F_\epsilon(x, a) - F_\epsilon(x, \hat{a}) \| \leq L_1 |a - \hat{a}|
\]

for all \( |a|, |\hat{a}| \leq a_0 \). Then the mappings \([-a_0, a_0] \to \mathcal{X}: a \mapsto x_\epsilon^a \) are also uniformly Lipschitz; that is, there is \( L_0 > 0 \) such that

\[
(4.21) \quad \sup_{0 < \epsilon < \epsilon_0} \| x_\epsilon^a - x_\epsilon^\hat{a} \| \leq L_0 |a - \hat{a}|
\]

for all \( |a|, |\hat{a}| \leq a_1 \).

4.3. Application of Lemma 7 We begin with a general observation about Fourier multipliers. The proof of this lemma follows from direct calculations with the norm

\[
\| \psi \|_{H_{\text{per}}}^2 = \sum_{k \in \mathbb{Z}} (1 + k^2)^r |\hat{\psi}(k)|^2,
\]

and so we omit it. Throughout this section, we denote by \( B(\mathcal{U}, \mathcal{V}) \) the space of bounded linear operators between normed spaces \( \mathcal{U} \) and \( \mathcal{V} \) and set \( B(\mathcal{U}) := B(\mathcal{U}, \mathcal{U}) \).

Lemma 8. Let \( \mu \) be a Fourier multiplier with symbol \( \tilde{\mu} \in L^\infty(\mathbb{R}) \) and let \( \omega \in \mathbb{R} \). As in Remark 5, let \( \mu^\omega \) be the Fourier multiplier with symbol \( \mu^\omega(k) = \tilde{\mu}(\omega k) \). Then

(i) \( \sup_{r, \omega \in \mathbb{R}} \| \mu^\omega \|_{B(H_{\text{per}}^r)} \leq \| \tilde{\mu} \|_{L^\infty(\mathbb{R})} \).

(ii) If \( \tilde{\mu} \) is Lipschitz, i.e., there is \( \text{Lip}(\tilde{\mu}) > 0 \) such that \( |\tilde{\mu}(k) - \tilde{\mu}(\hat{k})| \leq \text{Lip}(\tilde{\mu}) |k - \hat{k}| \), then

\[
\| (\mu^\omega - \mu^{\hat{\omega}}) \psi \|_{H_{\text{per}}^r} \leq \text{Lip}(\tilde{\mu}) |\omega - \hat{\omega}| \| \psi \|_{H_{\text{per}}^{r+1}}
\]

for all \( \omega, \hat{\omega}, r \in \mathbb{R} \) and \( \psi \in H_{\text{per}}^{r+1} \).

(iii) If there exist \( C, p > 0 \) such that

\[
|\tilde{\mu}(k)| \leq \frac{C}{(1 + k^2)^p}
\]

for all \( k \in \mathbb{R} \), then \( \| \mu \|_{B(H_{\text{per}}^r, H_{\text{per}}^{r+2p})} \leq C \).

Remark 10. Informally, Part (ii) of Lemma 8 means that taking a Lipschitz estimate for the map \( \omega \mapsto \mu^\omega \) costs us a derivative.

The following two lemmas on the Fourier multipliers \( \varpi^{\epsilon,K,r} \) and \( (\xi^{\epsilon,t})^{-1} \Pi_2 \) are the keys to our application of Lemma 7 to the maps \( \Psi_t \). They follow directly from the corresponding results for the symbols \( \tilde{\varpi}^{\epsilon,K,r} \) and \( (\tilde{\xi}^{\epsilon,t})^{-1} \), which are stated below as Lemmas 11 and 12 and proved in Section 9.2.
Lemma 9. (i) There exist $\epsilon_{11}, C_{\bar{\omega}_{\text{max}}}, 0$ such that
\[
\sup_{0 < \epsilon < \epsilon_{11}} \sup_{|t| \leq 1, r \in \mathbb{R}} \| \bar{\omega} \epsilon, K_{\epsilon, t} + t \|_{B(H_{\text{per}}, H_{\text{per}}^{r + 2})} \leq C_{\bar{\omega}_{\text{max}}}.
\]

(ii) There exists $C_{\bar{\omega}_{\text{Lip}}}, 0$ such that if $|t|, |\dot{t}| \leq 1$, then
\[
\sup_{0 < \epsilon < \epsilon_{11}} \sup_{r \in \mathbb{R}} \left\| \bar{\omega} \epsilon, K_{\epsilon, t} + t - \bar{\omega} \epsilon, K_{\epsilon, t} + \dot{t} \right\|_{B(H_{\text{per}}, H_{\text{per}}^{r + 2})} \leq C_{\bar{\omega}_{\text{Lip}}} |t - \dot{t}|.
\]

Lemma 10. (i) There exist $\epsilon_{12}, C_{\xi_{\text{max}}}, 0$ such that
\[
\sup_{0 < \epsilon < \epsilon_{12}} \sup_{|t| \leq 1, r \in \mathbb{R}} \| \epsilon^2 (\xi_{\epsilon, t})^{-1} \Pi_2 \|_{B(H_{\text{per}}, H_{\text{per}}^{r + 2})} \leq C_{\xi_{\text{max}}}.
\]

(ii) There exists $C_{\xi_{\text{Lip}}}, 0$ such that
\[
\sup_{0 < \epsilon < \epsilon_{12}} \sup_{r \in \mathbb{R}} \left\| \epsilon^2 (\xi_{\epsilon, t})^{-1} \Pi_2 - \epsilon^2 (\xi_{\epsilon, t})^{-1} \Pi_2 \right\|_{B(H_{\text{per}})} \leq C_{\xi_{\text{Lip}}} |t - \dot{t}|
\]

for all $|t|, |\dot{t}| \leq 1$.

Lemma 11. There exists $\epsilon_{11}, 0$ such that the following hold.
(i) There is $C_{\bar{\omega}_{\text{max}}}, 0$ such that
\[
(4.22) \sup_{0 < \epsilon < \epsilon_{11}} \sup_{k \in \mathbb{Z}} |\bar{\omega} \epsilon, K_{\epsilon, t}(k)| \leq \frac{C_{\bar{\omega}_{\text{max}}}}{1 + k^2}.
\]

(ii) There is $C_{\bar{\omega}_{\text{Lip}}}, 0$ such that
\[
(4.23) \sup_{0 < \epsilon < \epsilon_{11}} \sup_{k \in \mathbb{Z}} |\bar{\omega} \epsilon, K_{\epsilon, t}(k) - \bar{\omega} \epsilon, K_{\epsilon, t}(k)| \leq C_{\bar{\omega}_{\text{Lip}}} |t - \dot{t}|
\]

for all $|t|, |\dot{t}| \leq 1$.

Lemma 12. There exists $\epsilon_{12}, 0$ such that the following hold.
(i) There is $C_{\bar{\xi}_{\text{max}}}, 0$ such that
\[
(4.24) \sup_{0 < \epsilon < \epsilon_{12}} \sup_{k \in \mathbb{Z} \setminus \{-1, 1\}} \left| \frac{1}{\bar{\xi}_{\epsilon, t}(k)} \right| \leq \frac{C_{\bar{\xi}_{\text{max}}}}{1 + k^2}.
\]

(ii) There is $C_{\bar{\xi}_{\text{Lip}}}, 0$ such that
\[
(4.25) \sup_{0 < \epsilon < \epsilon_{12}} \sup_{k \in \mathbb{Z} \setminus \{-1, 1\}} \left| \frac{1}{\bar{\xi}_{\epsilon, t}(k)} - \frac{1}{\bar{\xi}_{\epsilon, t}(k)} \right| \leq C_{\bar{\xi}_{\text{Lip}}} |t - \dot{t}|.
\]

Last, Taylor’s theorem provides the following useful decomposition of $\tilde{\xi}_{\epsilon, t}$, which we prove in Section 9.2.
Lemma 13. For $0 < \epsilon < \epsilon_{12}$ and $\tau \in \mathbb{R}$, we have

$$\tilde{\xi}_c(\epsilon K_\epsilon + \tau) = \tilde{\xi}^i_c(\epsilon K_\epsilon)\tau + R_\epsilon(\tau)\tau^2,$$

where the functions $R_\epsilon$ have the following property: there exist $C_{R_{\text{max}}}, C_{R_{\text{Lip}}} > 0$ such that when $0 < \epsilon < \epsilon_{12}$,

$$\sup_{0 < \epsilon < \epsilon_{12}} |R_\epsilon(\tau)| \leq C_{R_{\text{max}}} \quad \text{and} \quad \sup_{0 < \epsilon < \epsilon_{12}} |R_\epsilon(\tau) - R_\epsilon(\hat{\tau})| \leq C_{R_{\text{Lip}}} |\tau - \hat{\tau}|$$

for all $\tau, \hat{\tau} \in \mathbb{R}$.

We are now ready to apply Lemma 7 to our map $\Psi_\epsilon$.

Proposition 14. Let $\epsilon_0 = \min\{\epsilon_{11}, \epsilon_{12}\}$. The maps $\Psi_\epsilon, 0 < \epsilon < \epsilon_0$, satisfy the conditions (4.18), (4.19), and (4.20) of Lemma 7 on the space $\mathcal{X}$ defined in (4.8) when $a_0 = r_0 = 1$.

Proof. We begin with some additional notation. Set $\mathcal{H}^r := \mathcal{H}_{\text{per}}^r \times \mathcal{H}_{\text{per}}^r, \|\psi\|_r := \|\psi\|_{\mathcal{H}^r}$, and

$$T_0^r(t) := \left[ \begin{array}{cc} c^{\epsilon, K_\epsilon + t} & 0 \\ 0 & e^2(\xi^t)^{-1}\Pi_2 \end{array} \right], \quad T_1^r(t) := \left[ \begin{array}{cc} 1 & 0 \\ 0 & \lambda^{(K_\epsilon + t)} \end{array} \right], \quad T_2^r(t) := J_2^{(K_\epsilon + t)}.$$

Lemmas 9 and 10 combine to produce constants $C_0, C_1, C_2 > 0$ such that the following estimates hold:

$$\sup_{0 < \epsilon < \epsilon_0, \epsilon \perp \epsilon_1, |t| \leq 1} \|T_0^r(t)\|_{\mathcal{B}^{(\mathcal{H}^r, \mathcal{H}^{r+2})}} \leq C_0$$

(4.29)

$$\sup_{0 < \epsilon < \epsilon_0, \epsilon \perp \epsilon_1, |t| \leq 1} \|T_1^r(t)\|_{\mathcal{B}^{(\mathcal{H}^r)}} \leq C_1, \quad i = 1, 2$$

(4.30)

$$\sup_{0 < \epsilon < \epsilon_0, \epsilon \perp \epsilon_1, |t| \leq 1} \|T_0^r(t) - T_0^r(\hat{t})\|_{\mathcal{B}^{(\mathcal{H}^r)}} \leq C_0 |t - \hat{t}|, \quad |t|, |\hat{t}| \leq 1$$

(4.31)

$$\sup_{0 < \epsilon < \epsilon_0, \epsilon \perp \epsilon_1, |t| \leq 1} \|T_1^r(t) - T_1^r(\hat{t})\|_{\mathcal{B}^{(\mathcal{H}^r, \mathcal{H}^{r-1})}} \leq C_1 |t - \hat{t}|, \quad |t|, |\hat{t}| \leq 1, \ i = 1, 2.$$

(4.32)

Define

$$G_\epsilon(\psi, t) = T_1^r(t)(T_2^r(t)(\nu + \psi))^2$$

(4.33)

$$F_\epsilon(\psi, t) = T_0^r(t)G_\epsilon(\psi, t).$$

The estimates (4.30) along with the Sobolev embedding estimate

$$\|\phi \psi\|_r \leq C_{sob, r}\|\phi\|_r\|\psi\|_r, \ \phi, \psi \in \mathcal{H}^r, \ r \geq 1,$$

give $M_{12, r} > 0$ such that

$$\sup_{0 < \epsilon < \epsilon_0, \epsilon \perp \epsilon_1, |t| \leq 1} \|G_\epsilon(\psi, t)\|_r \leq M_{12, r}(\|\psi\|_r^2 + \|\psi\|_r + 1).$$

(4.36)
We then use (4.29) to find
\[
\sup_{0 < \epsilon < \epsilon_0} \| F_\epsilon(\psi, t) \|_r \leq \sup_{0 < \epsilon < \epsilon_0} \| T^\epsilon_0(t) \|_{B(H^{-2}, H^r)} \| G_\epsilon(\psi, t) \|_{r-2} \leq C_0 M_{12} (\| \psi \|_{r-2}^2 + \| \psi \|_{r-2} + 1).
\]

Set \( M_{012} = C_0 M_{12} \). Since
\[
(4.37) \quad \begin{pmatrix} \Psi_{\epsilon,1}(\psi, t, a) \\ \Psi_{\epsilon,2}(\psi, t, a) \end{pmatrix} = -a F_\epsilon(\psi, t),
\]
we find
\[
(4.38) \quad \sup_{0 < \epsilon < \epsilon_0} \left\| \begin{pmatrix} \Psi_{\epsilon,1}(\psi, t, a) \\ \Psi_{\epsilon,2}(\psi, t, a) \end{pmatrix} \right\|_r \leq M_{012} |a| (\| \psi \|_{r-2}^2 + \| \psi \|_{r-2} + 1).
\]

We will return to the estimate (4.38) when we prove the bounds (4.3) for our fixed points. For now, we take \( r = 2 \) to obtain a constant \( M_2 > 0 \) such that
\[
\sup_{0 < \epsilon < \epsilon_0} \left\| \begin{pmatrix} \Psi_{\epsilon,1}(\psi, t, a) \\ \Psi_{\epsilon,2}(\psi, t, a) \end{pmatrix} \right\|_2 \leq M_2 |a|.
\]

This implies the first estimate (4.18) of Lemma 7 for the components \( \Psi_{\epsilon,1} \) and \( \Psi_{\epsilon,2} \).

To prove the second estimate (4.19) of Lemma 7, we first rewrite
\[
(4.39) \quad F_\epsilon(\psi, t) - F_\epsilon(\dot{\psi}, \dot{t}) = T^\epsilon_0(t) (G_\epsilon(\psi, t) - G_\epsilon(\dot{\psi}, \dot{t})) + (T^\epsilon_0(t) - T^\epsilon_0(\dot{t})) G_\epsilon(\dot{\psi}, \dot{t})
\]
and then find
\[
G_\epsilon(\psi, t) - G_\epsilon(\dot{\psi}, \dot{t}) = T'_1(t) (T_2^\epsilon(t) (\nu + \psi) + T_2^\epsilon(\dot{t}) (\nu + \dot{\psi})) \cdot [T_2^\epsilon(t) - T_2^\epsilon(\dot{t})] (\nu + \dot{\psi})
\]
\[
+ T'_1(t) T_2^\epsilon(t) (\nu + \psi) + T'_2(\dot{t}) (\nu + \dot{\psi}) \cdot [T_2^\epsilon(t) (\psi - \dot{\psi})
\]
\[
+ (T'_1(t) - T'_2(\dot{t})) (T_2^\epsilon(t) (\nu + \dot{\psi}))^2.
\]

We estimate the third term above; estimates for the first two terms follow by similar techniques. We have
\[
\| (T'_1(t) - T'_2(\dot{t})) (T_2^\epsilon(t) (\nu + \dot{\psi}))^2 \|_{r-2} \leq C_1 |t - \dot{t}| (T_2^\epsilon(t) (\nu + \dot{\psi}))^2 \|_{r-1} \text{ by (4.32)}
\]
\[
\leq C_1 C_{\text{sob}, r-1} |T_2^\epsilon(\dot{t}) (\nu + \dot{\psi})|^2 \|_{r-1} \text{ by (4.35)}
\]
\[
\leq C_1 C_{\text{sob}, r-1} C_2^2 \| \nu + \dot{\psi} \|^2_{r-1} \text{ by (4.30)}
\]
\[
\leq C_1 C_{\text{sob}, r-1} C_2^2 (\| \dot{\psi} \|^2_{r-1} + 2 \| \nu \|_{r-1} \| \dot{\psi} \|_{r-1} + \| \nu \|^2_{r-1})
\]
\[
\leq C_1 C_{\text{sob}, r-1} C_2^2 \max \{2 \| \nu \|_{r-1}, 1\} (\| \dot{\psi} \|^2_{r-1} + \| \dot{\psi} \|_{r-1} + 1).
\]
After comparable work on the other two terms, we ultimately arrive at a constant $L_{12,r} > 0$ such that
\begin{equation}
(4.40) \quad \sup_{0 < \epsilon < \epsilon_0} \| G_\epsilon(\psi, t) - G_\epsilon(\hat{\psi}, \hat{t}) \|_{r-2} \leq L_{12,r}(\| \hat{\psi} \|^2 + \| \psi \|^r + \| \hat{\psi} \|^r + 1)(\| \psi - \hat{\psi} \|_{r-1} + |t - \hat{t}|).
\end{equation}

We will need this estimate below when we work on $\Psi_{\epsilon,3}$. For now, we return to (4.39) and find
\begin{equation}
\| F_\epsilon(\psi, t) - F_\epsilon(\hat{\psi}, \hat{t}) \|_r \leq \| T_0^r(t) \|_{B(H^r, H^r)} \| G_\epsilon(\psi, t) - G_\epsilon(\hat{\psi}, \hat{t}) \|_{r-2} + \| T_0^r(t) - T_0^r(\hat{t}) \|_{B(H^r)} \| G_\epsilon(\hat{\psi}, \hat{t}) \|_r.
\end{equation}

Combining (4.31), (4.36), and (4.40) produces $L_{012,r} > 0$ such that
\begin{equation}
(4.41) \quad \sup_{0 < \epsilon < \epsilon_0} \| F_\epsilon(\psi, t) - F_\epsilon(\hat{\psi}, \hat{t}) \|_r \leq L_{012,r}(\| \psi \|^2 + \| \hat{\psi} \|^2 + \| \psi \|^r + \| \hat{\psi} \|^r)(\| \psi - \hat{\psi} \|_{r-1} + |t - \hat{t}|).
\end{equation}

Taking $r = 2$ and assuming $\| \psi \|_2, \| \hat{\psi} \|_2 \leq 1$, we find $L_2 > 0$ such that
\begin{equation}
\sup_{0 < \epsilon < \epsilon_0} \| F_\epsilon(\psi, t) - F_\epsilon(\hat{\psi}, \hat{t}) \|_2 \leq L_2(\| \psi - \hat{\psi} \|_2 + |t - \hat{t}|).
\end{equation}

This together with (4.37) proves the second estimate (4.19) of Lemma 7 for $\Psi_{\epsilon,1}$ and $\Psi_{\epsilon,2}$.

Now we proceed to study $\Psi_{\epsilon,3}$. Set
\begin{equation}
T_4(t) = \begin{bmatrix} 0 & 0 \\ 0 & \Pi_1 \end{bmatrix}
\end{equation}
and keep $T_1$ and $T_2$ as in (4.28). Here, however, we will only care about the case $r = 2$. Using the general bound
\begin{equation}
(4.42) \quad |\hat{\mathcal{F}}[f](k)| \leq \| f \|_{L_\infty} \leq C_{\text{sob,2}} \| f \|_{H^2_\text{per}},
\end{equation}
we find
\begin{equation}
|\Psi_{\epsilon,3}(\psi, t, a)| \leq \frac{\epsilon_0 C_{R_{\max}}}{l_0} t^2 + \frac{2C_{\text{sob,2}} \epsilon_0 |a|}{l_0} \| \Pi_1 \|_{H^2_\text{per}} \| \nu + \psi + \psi + \nu \|_{H^2_\text{per}}
\end{equation}
\begin{equation}
\leq \frac{\epsilon_0 C_{R_{\max}}}{l_0} t^2 + \frac{2C_{\text{sob,2}} \epsilon_0 |a|}{l_0} \| T_4 G_\epsilon(\psi, t) \|_2
\end{equation}
\begin{equation}
\leq \frac{\epsilon_0 C_{R_{\max}}}{l_0} t^2 + \frac{2C_{\text{sob,2}} \epsilon_0 |a|}{l_0} \| T_4 \|_{B(H^r)} \| M_{12} \|_{B(H^r)} |a|
\end{equation}
(\| \psi \|^2 + \| \psi \|^2 + 1) \text{ by (4.36}).

Thorough rearrangement of this last line, as well as the assumption $\| \psi \|_2, |a| \leq 1$, produces a constant $M_3 > 0$ such that
\begin{equation}
\sup_{0 < \epsilon < \epsilon_0} |\Psi_{\epsilon,3}(\psi, t, a)| \leq L_3(\| a \| + \| \psi \|^2 + |t|^2), \| \Psi \|_2, |t|, |a| \leq 1
\end{equation}
and this is sufficient to obtain the estimate (4.18) of Lemma 7 for $\Psi_{\epsilon,3}$.

The proof of estimate (4.19) for $\Psi_{\epsilon,3}$ is similar to the work above; we omit the details but mention that it uses the Fourier transform estimate (4.42), the uniform bounds on the functions $R_e$ from Lemma 13, and the Lipschitz estimate (4.40) for the functions $G_\epsilon$.

Last, the final bound (4.20) of Lemma 7 is easily established for the components $\Psi_{\epsilon,i}$ using the uniform bounds on the operators $T_i^r$ developed above; again, we omit the details.
Lemma 7 thus provides a number $a_0 > 0$ and, for all $0 < \epsilon < \epsilon_0$ and $|a| \leq a_0$, a unique pair $(\psi^a_\epsilon, \mathbf{t}^a_\epsilon) \in \{(\psi, t) \in X : \|\psi(t)\|_\infty \leq 1\}$ such that $\Psi_\epsilon(\psi^a_\epsilon, \mathbf{t}^a_\epsilon, a) = (\psi^a_\epsilon, \mathbf{t}^a_\epsilon)$. We may reverse each step of the conversion in Section 4.2 and we recall the scaling (4.5) and the decomposition (4.7) to find that the function

$$\theta(X) := a_0 \varphi_\epsilon^0(X) := a_0 \nu(\epsilon(K_\epsilon + t^a_\epsilon)X) + a_0 \psi(\epsilon K_\epsilon + t^a_\epsilon)X$$

solves (4.6). Defining $K^a_\epsilon := K_\epsilon + t^a_\epsilon$, we have the maps (4.1) and property (i) of Theorem 0. We prove the rest of the theorem below.

**Proof.** (of Theorem 6) Parts (ii), (iii), (iv) and (v)) When $a = 0$, the fixed-point property of $(\psi^0_{\epsilon,1}, \psi^0_{\epsilon,2}, \mathbf{t}^0_\epsilon)$ and the definition of $\Psi_\epsilon$ give

$$\psi^0_{\epsilon,1,2}(t^0_\epsilon) = \Psi_\epsilon(\psi^0_\epsilon, t^0_\epsilon, 0) = \left(0, 0, -\frac{\epsilon}{\xi^0_\epsilon(\epsilon K_\epsilon)} R_\epsilon(\epsilon t^0_\epsilon)(t^0_\epsilon)^2\right).$$

We see immediately that $\psi^0_{\epsilon,1} = \psi^0_{\epsilon,2} = 0$, which is Part (iii), and also

$$t^0_\epsilon = -\frac{\epsilon}{\xi^0_\epsilon(\epsilon K_\epsilon)} R_\epsilon(\epsilon t^0_\epsilon)(t^0_\epsilon)^2.$$ Scaling both sides by $\epsilon$ and rearranging, we find

$$0 = \xi^0_\epsilon(\epsilon K_\epsilon)(\epsilon t^0_\epsilon) + R_\epsilon(\epsilon t^0_\epsilon)(\epsilon t^0_\epsilon)^2 = \xi_\epsilon(\epsilon K_\epsilon + \epsilon t^0_\epsilon)$$

by (4.26). We may assume that we have taken $\epsilon_0$ to be so small that $\epsilon K_\epsilon + \epsilon t^0_\epsilon > 0$ for any $0 < \epsilon < \epsilon_0$ and $|t| \leq 1$, thus $\epsilon K_\epsilon + \epsilon t^0_\epsilon > 0$. By the uniqueness of positive roots of $\xi_\epsilon$ given in Part (vi) of Lemma 2 we have $\epsilon K_\epsilon + \epsilon t^0_\epsilon = \epsilon K_\epsilon$, hence $t^0_\epsilon = 0$ and $K^0_\epsilon = K_\epsilon$. So, Part (ii) holds.

For Part (iv), since $\psi_\epsilon^a \in \mathcal{Z}$, we know $\psi_\epsilon^a(\pm 1) \cdot \mathbf{j} = 0$, thus

$$\int_{-\pi}^{\pi} \psi^a_{\epsilon,2}(y) \sin(y) \, dy = \sum_{k \in \mathbb{Z}} \psi^a_{\epsilon,2}(k) \sin(k) = 0.$$ Last, for Part (v), by (2.8) in Lemma 2 we have positive constants $m_*(w)$ and $m^*(w)$, depending only on $w$, such that

$$m_*(w) \leq \epsilon K_\epsilon \leq m^*(w), \quad 0 < \epsilon < 1.$$ This shows $K_\epsilon = \mathcal{O}(1/\epsilon)$ and also allows us to estimate

$$|\epsilon K^a_\epsilon| = |\epsilon K_\epsilon + \epsilon t^a_\epsilon| \leq m^*(w) + 1.$$ Next, relying on the notation of the proof of Proposition 14, when $r = 2$ we have

$$\sup_{0<\epsilon<\epsilon_0} \|\psi^a_\epsilon\|_2 \leq \epsilon r_0 \leq 1$$

by Lemma 7 and when $r > 2$, (4.38) implies the bootstrap estimate

$$\|\psi^a_\epsilon\|_r = \left\|\left(\begin{array}{c} \psi_{\epsilon,1}^a \psi_{\epsilon,2}^a \end{array}\right)\right\|_r \leq M_{012}(\|\psi^a_\epsilon\|_{r-1}^2 + \|\psi^a_\epsilon\|_{r-1} + 1).$$
for some $|\epsilon K_\epsilon| \leq 4.45$, and use the Sobolev embedding theorem to produce

For the uniform Lipschitz bound $4.44$, we first apply the uniform Lipschitz condition $4.21$ guaranteed by Lemma 7 to the fixed points $(\psi_\epsilon^a, t_\epsilon^a)$ and compute

\begin{equation}
K_\epsilon^a - K_\epsilon^b + \|\psi_\epsilon^a - \psi_\epsilon^b\|_2 \leq |t_\epsilon^a - t_\epsilon^b| + \|\psi_\epsilon^a - \psi_\epsilon^b\|_2 \leq L_1 |a - \dot{a}|
\end{equation}

for some $L_1 > 0$. For $r > 2$, the estimate $4.41$ gives

\begin{equation}
\|\psi_\epsilon^a - \psi_\epsilon^b\|_r \leq F_r(\psi_\epsilon^a, t_\epsilon^a) - F_r(\psi_\epsilon^b, t_\epsilon^b),
\end{equation}

\begin{equation}
\leq L_{012r}(\|\psi_\epsilon^a\|_r^2 + \|\dot{\psi}_\epsilon^a\|_r^2 + \|\ddot{\psi}_\epsilon^a\|_r, \|\dot{\psi}_\epsilon^b\|_r, \|\ddot{\psi}_\epsilon^b\|_r)(\|\psi_\epsilon^a - \psi_\epsilon^b\|_{r-1} + |t_\epsilon^a - t_\epsilon^b|)
\end{equation}

for each $0 < \epsilon < \epsilon_0$. We bound the factor

\begin{equation}
\|\psi_\epsilon^a\|_r^2 + \|\dot{\psi}_\epsilon^a\|_r^2 + \|\ddot{\psi}_\epsilon^a\|_r \leq L_1 |a - \dot{a}|
\end{equation}

by $4.3$ and estimate $|t_\epsilon^a - t_\epsilon^b| \leq L_1 |a - \dot{a}|$ as before to find

\begin{equation}
\|\psi_\epsilon^a - \psi_\epsilon^b\|_r \leq L_r(\|\psi_\epsilon^a - \psi_\epsilon^b\|_{r-1} + |a - \dot{a}|)
\end{equation}

for some $L_r > 0$ and all $0 < \epsilon < \epsilon_0$. Taking the existing Lipschitz estimate on $|K_\epsilon^a - K_\epsilon^b|$ from $4.45$, using the Sobolev embedding theorem, and inducting on $r$ produces the final Lipschitz estimate $4.4$ of Part (v).

4.4. Proof of Lemma 7. We set

\begin{equation}
r_0 = \min\left\{\frac{1}{6C_1}, r_1\right\} \quad \text{and} \quad a_0 = \min\left\{\frac{r_0}{6C_1}, \frac{1}{6C_1}, a_1\right\}.
\end{equation}

Then whenever $0 < \epsilon < \epsilon_0, \|x\| \leq r_0, |a| \leq a_0$, we have

\begin{equation}
\|F_\epsilon(x, a)\| \leq C_1(a_0 + a_0 r_0 + \epsilon^2 r_0^2) \leq C_1\left(\frac{r_0}{6C_1} + \frac{r_0}{6C_1} + \frac{r_0}{6C_1}\right) = \frac{r_0}{2} < r_0.
\end{equation}

Moreover,

\begin{equation}
C_1(|a| + \|x\| + \|y\|) \leq C_1\left(\frac{1}{6C_1} + \frac{1}{6C_1} + \frac{1}{6C_1}\right) = \frac{1}{2}
\end{equation}

whenever $|a| \leq a_0, \|x\|, \|y\| \leq r_0$. So, $4.19$ gives

\begin{equation}
\|F_\epsilon(x, a) - F_\epsilon(y, a)\| \leq \frac{1}{2}\|x - y\|
\end{equation}

for all such $a, x, y$. Thus have the uniform contraction condition.

We conclude that for each $0 < \epsilon < \epsilon_0$ and $|a| \leq a_0$, $F_\epsilon(\cdot, a)$ maps $B(r_0)$ into itself and is a contraction (with uniform constant $1/2$). By Banach’s fixed point theorem, for each $0 < \epsilon < \epsilon_0$ and $|a| \leq a_0$, we then have a unique $x_\epsilon^a \in B(r_0)$ such that $F_\epsilon(x_\epsilon^a, a) = x_\epsilon^a$.

For the Lipschitz estimate on the mappings $a \mapsto x_\epsilon^a$, compute, for $|a| \leq a_0$,

\begin{equation}
\|x_\epsilon^a - x_\epsilon^b\| = \|F_\epsilon(x_\epsilon^a, a) - F_\epsilon(x_\epsilon^a, \dot{a})\|
\end{equation}

\begin{equation}
\leq \|F_\epsilon(x_\epsilon^a, a) - F_\epsilon(x_\epsilon^a, \dot{a})\| + \|F_\epsilon(x_\epsilon^a, \dot{a}) - F_\epsilon(x_\epsilon^a, \ddot{a})\|
\end{equation}
\[ \leq L_1|a - \dot{a}| + \frac{1}{2}\|x^a_\varepsilon - x^\dot{a}_\varepsilon\| \text{ by (4.20) and (4.46)}. \]

Hence
\[ \|x^a_\varepsilon - x^\dot{a}_\varepsilon\| \leq 2L_1|a - \dot{a}| \]
for all \(|a| \leq a_0\) and \(0 < \varepsilon < \varepsilon_0\).

5. The nanopteron equations

5.1. Beale’s ansatz. Following [Bea91], we let
\[ \eta(X) := \left( \begin{array}{c} \eta_1(X) \\ \eta_2(X) \end{array} \right) \]
and look for a solution of (2.27) of the form
\[ \theta = \sigma + a\varphi^a + \eta. \]

In the above there are three unknowns:
- the function \(\eta_1\) (which will be an even exponentially decaying function),
- the function \(\eta_2\) (which will be an odd exponentially decaying function) and
- the amplitude of the periodic part, \(a \in \mathbb{R}\).

Remark 11. Since \(\sigma = \sigma i\) and \(\varphi^0 = \sin(K_iX)j\), we see that the principal contribution in the first slot is connected to the acoustic branch and to the optical branch in the second slot, as described above.

One finds that \(\eta\) solves the system:
\[ \begin{align*}
\eta_1 + 4(1+w)\varpi^0 (\sigma \eta_1) &= j_1 + j_2 + j_3 + j_4 + j_5 \\
\epsilon^2 (c_w^2 + c^2)\eta_2'' + \lambda^s \eta_2 &= \epsilon^2 (l_1 + l_2 + l_3 + l_4 + l_5)
\end{align*} \]

where
\[ \begin{align*}
j_1 := & - (\sigma + \varpi^s b^0_1(\sigma, \sigma)) \\
j_2 := & - (2\varpi^s b^0_1(\sigma, \eta) - 2\varpi^0 b^0_1(\sigma, \eta)) \\
j_3 := & - 2\varpi^s b^0_1(\sigma, \varphi^0) \\
j_4 := & - 2\varpi^s b^0_1(\eta, \varphi^0) \\
j_5 := & - 2\varpi^s b^0_1(\eta, \eta)
\end{align*} \]

\[ \begin{align*}
l_1 := & - \lambda^s b^0_2(\sigma, \sigma) \\
l_2 := & - 2\lambda^s b^0_2(\sigma, \eta) \\
l_3 := & - 2\lambda^s b^0_2(\sigma, \varphi^0) \\
l_4 := & - 2\lambda^s b^0_2(\eta, \varphi^0) \\
l_5 := & - \lambda^s b^0_2(\eta, \eta)
\end{align*} \]

We used the fact that \(2\varpi^0 b^0_1(\sigma, \eta) = 4(1+w)\varpi^0 (\sigma \eta_1)\).

The operator
\[ \mathcal{A} := 1 + 4(1+w)\varpi^0 (\sigma \cdot) \]
was studied in [FP99] and is invertible the class of even functions. This is made precise below in Theorem 20. Thus we can rewrite the first equation in (5.2) as
\[ \eta_1 = \mathcal{A}^{-1} (j_1 + j_2 + j_3 + j_4 + j_5) =: N^s_1(\eta, a). \]
5.2. The solvability condition of $T_\epsilon$. On the other hand
\begin{equation}
T_\epsilon := \epsilon^2 (c_0^2 + \epsilon^2) \partial_X^2 + \lambda^\epsilon
\end{equation}
is not so nice. If we take the Fourier transform of the equation
\begin{equation}
T_\epsilon f = g
\end{equation}
we find that
\begin{equation}
\tilde{T}_\epsilon(K) \hat{f}(K) = \hat{g}(K)
\end{equation}
where $\tilde{T}_\epsilon(K) = -\epsilon^2 (c_0^2 + \epsilon^2) K^2 + \tilde{\lambda}_\epsilon(\epsilon K)$.

In [4.2] of Theorem 6 we saw that there exists a unique $K_\epsilon > 0$ such that $\tilde{T}_\epsilon(\pm K_\epsilon) = 0$. Also $K_\epsilon = \mathcal{O}(1/\epsilon)$. Since we have $\tilde{T}_\epsilon(\pm K_\epsilon) = 0$ we see, by virtue of (5.7), that
\begin{equation}
T_\epsilon f = g \implies \hat{g}(\pm K_\epsilon) = 0.
\end{equation}
Which is to say that $T_\epsilon$ in not surjective. (It is injective.) The appropriate way to view (5.8) is as a pair of solvability conditions for (5.6); it turns out that if the integral conditions are met then there is a solution $f$ of $T_\epsilon f = g$. In this case we write $f = T_\epsilon^{-1} g$. This is made precise below in Lemma 24.

Note that if $f$ is odd, so is $g = T_\epsilon f$. And therefore so is $\hat{g}(K)$. Which means that we can eliminate one of the solvability conditions in (5.8). In particular, if $f$ is odd then
\begin{equation}
T_\epsilon f = g \implies \iota_\epsilon[g] := \int_{\mathbb{R}} g(X) \sin(K_\epsilon X) dX = 0.
\end{equation}

5.3. The modified equation for $\eta_2$ and an equation for $a$. Thus (5.9) implies any solution of (5.2) has
\begin{equation}
\iota_\epsilon[l_1 + l_2 + l_3 + l_4 + l_5] = 0.
\end{equation}

Following [Bea91] and [AT92], we will use this condition to “select the amplitude $a$.”

To this end, we let
\begin{equation}
\chi_\epsilon(X) := \chi_\epsilon \cdot j := \lambda^\epsilon \cdot j \quad \text{where} \quad \nu_\epsilon(X) := \nu_\epsilon(X) = \sin(K_\epsilon X) j.
\end{equation}

We claim that
\begin{equation}
l_{31} := l_3 + 2a \chi_\epsilon
\end{equation}
is “small”, though we hold off on a precise estimate for the time being. Roughly what we mean is that $l_{31}$ contains terms which are either of size comparable to $\epsilon$, or are quadratic in $a$. We also claim that
\begin{equation}
\kappa_\epsilon := \iota_\epsilon[\chi_\epsilon]
\end{equation}
is large in the sense that it is strictly bounded away from zero by an amount that does not depend on $\epsilon$. Both these claims are verified below (in (8.8) and (7.25)). With this definition we can rewrite (5.10) as
\begin{equation}
a = \frac{1}{2\kappa_\epsilon} \iota_\epsilon[l_1 + l_2 + l_{31} + l_4 + l_5] =: N_3^\epsilon(\eta, a).
\end{equation}
Next we modify the second equation in (5.2) to
\[ \mathcal{T}_f \eta_2 = -2 \epsilon^2 a \chi_{\epsilon} + \epsilon^2 (l_1 + l_2 + l_{31} + l_4 + l_5) \]
\[ - \frac{1}{\kappa_{\epsilon}} \iota_{\epsilon} \left[ -2 \epsilon^2 a \chi_{\epsilon} + \epsilon^2 (l_1 + l_2 + l_{31} + l_4 + l_5) \right] \chi_{\epsilon}. \]
(5.12)

By design,
\[ \iota_{\epsilon} \left[ -2 \epsilon^2 a \chi_{\epsilon} + \epsilon^2 (l_1 + l_2 + l_{31} + l_4 + l_5) \right] \chi_{\epsilon} = 0. \]
Which is to say that the right hand side of (5.12) meets the solvability condition (5.9) and we can apply \( \mathcal{T}_f^{-1} \) to it. Also, if (5.11) is met then the term in the second row of (5.12) vanishes and so the right hand side of (5.12) agrees exactly with the right hand side of the second equation in (5.2). Also note that \( 2 \epsilon^2 a \chi_{\epsilon} - \frac{1}{\kappa_{\epsilon}} \iota_{\epsilon} [2 \epsilon^2 a \chi_{\epsilon}] \chi_{\epsilon} = 0. \)

So if we put
\[ \mathcal{P}_f f := \mathcal{T}_f^{-1} \left( f - \frac{1}{\kappa_{\epsilon}} \iota_{\epsilon} [f] \chi_{\epsilon} \right) \]
then (5.12) is equivalent to
\[ \eta_2 = \epsilon^2 \mathcal{P}_f (l_1 + l_2 + l_{31} + l_4 + l_5) =: N_2^\epsilon (\eta, a). \]
(5.13)

**Remark 12.** Stating things more abstractly, what we know is that the cokernel of \( \text{diag}(A, \mathcal{T}_f) \) is nontrivial, due to the solvability conditions (5.8). The classical method for the analysis of nonlinear problems where the cokernel (or, more typically, the kernel) of the linear part is nontrivial is the Liapunov-Schmidt decomposition, like we used in the construction of the periodic solutions. But in our case we have the additional complication that \( \text{diag}(A, \mathcal{T}_f) \) is injective. Which means that its Fredholm index is negative. It is this feature that results in having different pieces of our problem living in different sorts of function spaces (namely localized and periodic) as opposed to the whole argument taking place in \( E_1^1 \times O_1^1 \).

Another less precise, but perhaps more evocative way, of saying this is to say that we want to do a regular old Liapunov-Schmidt analysis but the function we want to be the basis for the kernel of \( \mathcal{T}_f \)—specifically \( \sin(K_X) \)—is not in our function space. And so we need to come up with a way to include periodic functions in the solution at the same time as the localized functions. Which leads us to Beale’s ansatz (5.1). At the end of the day, the equation for the periodic amplitude \( a, (5.11) \), can viewed as being the replacement for “the projection of (5.2) onto the kernel” which would appear in a more standard Liapunov-Schmidt analysis. Likewise \( \eta_1, (5.4) \) and, more relevantly, \( \eta_2, (5.13) \) are the replacements for “the projection onto the orthogonal complement of the kernel.”

**5.4. The final system.** In short, if we can solve the system
\[ \eta_1 = N_1^\epsilon (\eta_1, \eta_2, a) \]
\[ \eta_2 = N_2^\epsilon (\eta_1, \eta_2, a) \]
\[ a = N_3^\epsilon (\eta_1, \eta_2, a) \]
then we will have found a solution of our problem. Observe that (5.14) is written such that solutions are fixed points of the map \( N^\epsilon := (N_1^\epsilon, N_2^\epsilon, N_3^\epsilon) \). We would achieve our goal if we
could show that $N^\epsilon$ is a contraction on a suitable function space. It turns out that the right hand side has some problems in that regard, due principally to the terms $j_4$ and $l_4$. These have a Lipschitz constant with respect to $a$ that depends in a bad way on $\eta$. Nevertheless, a modified contraction mapping argument will get the job done. But first we need many estimates.

6. Existence/uniqueness/regularity/magnitude

6.1. Function spaces. For $r \geq 0$ and $p \in [1, \infty]$, let $W^{r,p}(\mathbb{R})$ be the usual Sobolev space of $r$-times (weakly) differentiable functions in $L^p(\mathbb{R})$. The norms on these spaces will be denoted by $\|\cdot\|_{W^{r,p}}$. Put $H^r(\mathbb{R}) := W^{r,2}(\mathbb{R})$, per the usual convention.

For $r \geq 0$ and $q \geq 0$, let

$$H^r_q := \{ f \in H^r(\mathbb{R}) : \cosh(q) \cdot f(\cdot) \in H^r(\mathbb{R}) \}.$$  

$H^r_q$ consists of those functions in $H^r(\mathbb{R})$ which, roughly speaking, behave like $e^{-q|\cdot|}$ as $|\cdot| \to \infty$. Let

$$E^r_q := H^r_q \cap \{ \text{even functions}\} \quad \text{and} \quad O^r_q := H^r_q \cap \{ \text{odd functions}\}.$$  

Each of these is a Hilbert space with inner product given by

$$(f,g)_{r,q} := (\cosh(q)f, \cosh(q)g)_{H^r(\mathbb{R})}$$

where $(\cdot, \cdot)_{H^r(\mathbb{R})}$ is the usual $H^r(\mathbb{R})$ inner product. Of course we denote $\|f\|_{r,q} := \sqrt{(f,f)_{r,q}}$.

We abuse notation slightly and, for elements $u$ of $H^r_q \times H^r_q$, write $\|u\|_{H^r_q \times H^r_q} = \|u\|_{r,q}$. We will show that (5.14) has a solution in $E^1_q \times O^1_q \times \mathbb{R}$ for some $q > 0$.

6.2. Key estimates. As mentioned above, the existence proof is an iterative argument modeled on the proof of Banach’s contraction mapping theorem. The following proposition contains all the necessary estimates for proving existence and uniqueness. It also contains estimates which will be used in a bootstrap argument which will show that the solution is smooth and, more interestingly, that the amplitude of the periodic piece “a” is small beyond all orders of $\epsilon$.

**Proposition 15.** For all $w > 1$ there exists $\epsilon_* \in (0,1)$, $q_* > 0$ and $C_* > 1$ such that we have the following properties.

(i) (Mapping estimates) For all

$$\eta \in E^1_q \times O^1_q, \quad 0 < \epsilon \leq \epsilon_*, \quad \frac{1}{2} q_* \leq q \leq q_* \quad \text{and} \quad -a_0 \leq a \leq a_0$$

we have $N^1_1(\eta,a) \in E^1_q$ and $N^2_2(\eta,a) \in O^1_q$ together with the estimate:

$$\|N^1_1(\eta,a)\|_{1,q} + \|N^2_2(\eta,a)\|_{1,q} + |N^3_3(\eta,a)| \leq C_* (\epsilon + \epsilon \|\eta\|_{1,q} + \epsilon |a| + \|\eta\|^2_{1,q} + a^2).$$ (6.1)

(ii) (Lipschitz-type estimates) For all

$$\eta, \dot{\eta} \in E^1_{q'} \times O^1_{q'}, \quad 0 < \epsilon \leq \epsilon_*, \quad \frac{1}{2} q_* \leq q < q' \leq q_* \quad \text{and} \quad -a_0 \leq a \leq \dot{a} \leq a_0$$
Similarly, (6.2) implies
\[ \|N_1^r(\eta, a) - N_1^r(\tilde{\eta}, \tilde{a})\|_{1,q} + \|N_2^r(\eta, a) - N_2^r(\tilde{\eta}, \tilde{a})\|_{1,q} + \|N_3^r(\eta, a) - N_3^r(\tilde{\eta}, \tilde{a})\|_{1,q} \leq C_* \frac{1}{|q - q'|} (\epsilon + \|\eta\|_{1,q'} + \|\tilde{\eta}\|_{1,q'} + |a| + |\tilde{a}|) (|a - \tilde{a}| + \|\eta - \tilde{\eta}\|_{1,q}). \]

(iii) **Bootstrap estimates** For all \( r \geq 1 \) there exists \( C_{*,r} > 1 \) such that for all \( \eta \in E^r_q \times O^r_q \), \( 0 < \epsilon \leq \epsilon_* \), \( \frac{1}{2} q_* \leq q \leq q_* \) and \( -a_0 \leq a \leq a_0 \)

we have \( N_1^r(\eta, a) \in E^{r+1}_q \) and \( N_2^r(\eta, a) \in O^{r+1}_q \) together with the estimates:

\[ \|N_1^r(\eta, a)\|_{r+1,q} + \|N_2^r(\eta, a)\|_{r+1,q} \leq C_{*,r} (\epsilon + \|\eta\|_{r,q} + \epsilon^{1-r}|a| + \epsilon^{-r}a^2 + \epsilon^{-r}|a||\eta|_{r,q} + \|\eta\|_{r,q}^2) \]

and

\[ |N_3^r(\eta, a)| \leq C_{*,r} (\epsilon^{r+1} + \epsilon^r|\eta|_{r,q} + \epsilon|a| + a^2 + |a||\eta|_{r,q} + \epsilon^r|\eta|_{r,q}^2). \]

The proof of this proposition is lengthy, byzantine and postponed to until Sections 7 and 8 below. Onward to existence.

### 6.3. Existence

Let
\[ X_q := E^1_q \times O^1_q \times \mathbb{R}. \]

This is a Banach space with norm \( \| \cdot \|_{X_q} \) defined in the obvious way.

Fix \( w > 1 \) and take \( \epsilon_* \) and \( q_* \) as in Proposition 15. If we put \( \eta = (\eta, a) \) and \( \tilde{\eta} = (\tilde{\eta}, \tilde{a}) \) then the estimate (6.1) is compressed to

\[ \|N^r(\eta)\|_{X_q} \leq C_* (\epsilon + \epsilon\|\eta\|_{X_q} + \|\eta\|_{X_q}^2). \]

Similarly, (6.2) implies

\[ \|N^r(\eta) - N^r(\tilde{\eta})\|_{X_q} \leq \frac{C_*}{|q - q'|} (\epsilon + \epsilon\|\eta\|_{X_q} + \|\tilde{\eta}\|_{X_q} - \|\eta - \tilde{\eta}\|_{X_q}). \]

Here we have the same restrictions on \( q, q', \epsilon \) as in the proposition, of course.

Put
\[ \bar{\epsilon} := \min \left( \epsilon_*, \frac{1}{2(C_* + 2C_*^2); \frac{q_*}{8(C_* + 4C_*^2)} \right). \]

Henceforth we assume that \( \epsilon \in (0, \bar{\epsilon}) \). Suppose that

\[ \|\eta\|_{q_*} \leq 2C_*\epsilon. \]

Then (6.5), (6.7) and the definition of \( \bar{\epsilon} \) imply

\[ \|N^r(\eta)\|_{X_{q_*}} \leq C_* (\epsilon + 2C_*\epsilon^2 + 4C_*^2\epsilon^2) \leq C_* \epsilon (1 + (2C_* + 4C_*^2)\bar{\epsilon}) \leq 2C_*\epsilon. \]

Now select \( \eta^1 \in X_{q_*} \) with \( \|\eta^1\|_{q_*} \leq 2C_*\epsilon \). For \( j \geq 1 \), put

\[ \eta^{j+1} = N^r(\eta^j). \]

A simple induction argument using (6.8) shows that, for all \( j \in \mathbb{N} \), we have

\[ \|\eta^{j+1}\|_{X_{q_*}} \leq 2C_*\epsilon. \]
Thus we see that \( \{n^j\}_{j \in \mathbb{N}} \) is a uniformly bounded sequence in \( X^q \) (and therefore uniformly bounded in all spaces \( X^q \) with \( q \leq q_* \) too).

We now demonstrate that this sequence is Cauchy in \( X_{3q_*/4} \). Fix \( j \geq 2 \). Then (6.9) and (6.6) (with \( q = 3q_*/4 \) and \( q' = q_* \)) imply
\[
\|n^{j+1} - n^j\|_{X_{3q_*/4}} = \|N^\epsilon(n^j) - N^\epsilon(n^{j-1})\|_{X_{3q_*/4}} \\
\leq 4C_\epsilon q_*^{-1}(\epsilon + \|n^j\|_{X^q} + \|n^{j-1}\|_{X^q}) \|n^j - n^{j-1}\|_{X_{3q_*/4}}.
\]

We use use (6.10) in the first term to get
\[
\|n^{j+1} - n^j\|_{X_{3q_*/4}} \leq 4C_\epsilon q_*^{-1}(\epsilon + 4C_\epsilon \epsilon) \|n^j - n^{j-1}\|_{X_{3q_*/4}}
\]
for all \( j \geq 2 \).

Using the fact that \( \epsilon \in (0, \bar{\epsilon}) \) and the definition of \( \bar{\epsilon} \) we see that \( 4C_\epsilon q_*^{-1}(\epsilon + 4C_\epsilon \epsilon) \leq 1/2 \).

Thus
\[
\|n^{j+1} - n^j\|_{X_{3q_*/4}} \leq \frac{1}{2} \|n^j - n^{j-1}\|_{X_{3q_*/4}}
\]
for all \( j \geq 1 \).

Now fix \( m > n \geq 1 \). The triangle inequality, followed by (6.11) and the geometric series summation formula give:
\[
\|n^m - n^n\|_{X_{3q_*/4}} \leq \sum_{j=n}^{m-1} \|n^{j+1} - n^j\|_{X_{3q_*/4}} \leq 8C_\epsilon \epsilon \sum_{j=n}^{m-1} 2^{-j} \leq 8C_\epsilon \epsilon \sum_{j=n}^{\infty} 2^{-j} = \frac{16C_\epsilon \epsilon}{2^n}.
\]
Thus we can make \( \|n^m - n^n\|_{X_{3q_*/4}} \) as small as we like by taken \( m, n \) sufficiently large, which means that the sequence is Cauchy. Which means it converges. Call the limit \( n_\epsilon = (n_\epsilon, a_\epsilon) \in X_{3q_*/4} \). Because of (6.10), we have
\[
\|n_\epsilon\|_{X_{3q_*/4}} \leq 2C_\epsilon \epsilon.
\]

Now we claim that
\[
n_\epsilon = N^\epsilon(n_\epsilon)
\]
which would imply that \( n_\epsilon \) is the solution we are looking for. Since the convergence of \( n^j \) is in \( X_{3q_*/4} \), if we knew that \( N^\epsilon \) was continuous on that space we would have our claim by passing the limit through \( N^\epsilon \) in (6.9). But \( N^\epsilon \) is not obviously continuous. One can see this in the fact that the Lipschitz constant in (6.6) depends on \( \|n\|_{X^{q'}} \) with \( q' > q \). We do know that \( N^\epsilon(n_\epsilon) \in X_{3q_*/4} \) by virtue of (6.5).

But nonetheless we have (6.13). Since \( n^j \) converges in \( X_{3q_*/4} \), the scheme (6.9) implies
\[
N^\epsilon(n^j) \to n_\epsilon
\]
too. This convergence takes place in \( X^q \) for all \( q \in [0, 3q_*/4] \). So look at
\[
\|N^\epsilon(n_\epsilon) - n_\epsilon\|_{X_{q*/2}}.
\]
Note that we are estimating this in the bigger space $\mathcal{X}_{q_r/2}$, not $\mathcal{X}_{3q_r/4}$. The triangle inequality shows that
\[
\|N^\varepsilon(n_c) - n_c\|_{\mathcal{X}_{q_r/2}} \leq \|N^\varepsilon(n) - N^\varepsilon(n^j)\|_{\mathcal{X}_{q_r/2}} + \|N^\varepsilon(n^j) - n_c\|_{\mathcal{X}_{q_r/2}}.
\]
The second term can be made as small as we like by taking $j$ big enough because of (6.14). For the first term we use (6.6):
\[
\|N^\varepsilon(n_c) - N^\varepsilon(n^j)\|_{\mathcal{X}_{q_r/2}} \leq 4C_* q_*^{-1} \left( \varepsilon + \|n_c\|_{\mathcal{X}_{3q_r/4}} + \|n^j\|_{\mathcal{X}_{3q_r/4}} \right) \|n_c - n^j\|_{\mathcal{X}_{q_r/2}}.
\]
Using (6.10) and (6.12) this becomes:
\[
\|N^\varepsilon(n_c) - N^\varepsilon(n^j)\|_{\mathcal{X}_{q_r/2}} \leq 4C_* q_*^{-1} \varepsilon (1 + 4C_* \varepsilon) \|n_c - n^j\|_{\mathcal{X}_{q_r/2}}.
\]
Since $n^j \to n_c$ in $\mathcal{X}_{3q_r/4}$ it also converges in $\mathcal{X}_{q_r/2}$. And thus we can make the above term as small as we want by taking $j$ sufficiently large. Which is to say that $\|N^\varepsilon(n_c) - n_c\|_{\mathcal{X}_{q_r/2}} = 0$. Thus we have (6.13). Which is to say, there exists a solution of (5.14).

6.4. Uniqueness. Suppose that $\hat{n}_c \in \mathcal{X}_{3q_r/4}$ has the property that $\hat{n} = N^\varepsilon(\hat{n}_c)$ and $\|\hat{n}_c\|_{\mathcal{X}_{3q_r/4}} \leq 2C_* \varepsilon$ and $\varepsilon \in (0, \bar{\varepsilon}]$. Clearly
\[
\hat{n}_c - n_c = N^\varepsilon(\hat{n}_c) - N^\varepsilon(n_c).
\]
Applying (6.6) with $q = q_r/2$ and $q' = 3q_r/4$ gives:
\[
\|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}} \leq 4C_* q_*^{-1} \left( \varepsilon + \|\hat{n}_c\|_{\mathcal{X}_{3q_r/4}} + \|n_c\|_{\mathcal{X}_{3q_r/4}} \right) \|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}}.
\]
Since $\|\hat{n}_c\|_{\mathcal{X}_{3q_r/4}} \leq 2C_* \varepsilon$ and $\|n_c\|_{\mathcal{X}_{3q_r/4}} \leq 2C_* \varepsilon$ we have
\[
\|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}} \leq 4C_* q_*^{-1} (\varepsilon + 4C_* \varepsilon) \|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}}.
\]
As above, we saw that $\varepsilon \in (0, \bar{\varepsilon}]$ implies $4C_* q_*^{-1} (\varepsilon + 4C_* \varepsilon) \leq 1/2$. Thus we have
\[
\|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}} \leq \frac{1}{2} \|\hat{n}_c - n_c\|_{\mathcal{X}_{q_r/2}}
\]
which implies $\hat{n}_c = n_c$. And so $n_c = (\eta_c, a_c)$ is the unique fixed point of $N^\varepsilon$ in the ball of radius $2C_* \varepsilon$ in $\mathcal{X}_{3q_r/4}$.

6.5. Regularity of $\eta_c$ and the size of $a_c$. We claim that for all $r \geq 1$, there exists $C_r > 0$ such that for all $\varepsilon \in (0, \bar{\varepsilon}]$ the fixed points $(\eta_c, a_c)$ constructed above satisfy
\[
(6.15) \quad \|\eta_c\|_{r,3q_r/4} \leq C_r \varepsilon \quad \text{and} \quad |a_c| \leq C_r \varepsilon^r.
\]
We prove this by induction. The original construction of $(\eta_c, a_c)$ was done in the ball of radius $2C_* \varepsilon$ in the space $\mathcal{X}_{3q_r/4}$ and so we have the $r = 1$ base case:
\[
\|\eta_c\|_{1,3q_r/4} \leq 2C_* \varepsilon \quad \text{and} \quad |a_c| \leq 2C_* \varepsilon.
\]
Now suppose that (6.15) holds for some $r \geq 1$. We know that $(\eta_c, a_c) = N^\varepsilon(\eta_c, a_c)$. Therefore, using (6.3) we see:
\[
\|\eta_c\|_{r+1,3q_r/4} \leq \|N_1(\eta_c, a_c)\|_{r+1,3q_r/4} + \|N_2(\eta_c, a_c)\|_{r+1,3q_r/4}
\leq C_r \varepsilon \left( \varepsilon + \|\eta_c\|_{r,3q_r/4} + \varepsilon^{1-r} |a_c| + \varepsilon^{-r} a_c^2 + \varepsilon^{-r} |a_c| \|\eta_c\|_{r,3q_r/4} + \|\eta_c\|_{r,3q_r/4}^2 \right).
\]
Using the inductive hypothesis (6.15) gives:
\[ \|\eta\|_{r+1,3q/4} \leq C_{r+1} (\epsilon + C_r \epsilon + C_r^2 \epsilon^r + C_r^2 \epsilon^2 + C_r^2 \epsilon^2) \leq C_{r+1} \epsilon. \]
We are half way done.

Using (6.4) we have
\[ |a_c| = |N_3(\eta, a_c)| \leq C_{r+1} (\epsilon^{r+1} + \epsilon^r \|\eta\|_{r+1,3q/4} + \epsilon |a_c| + |a_c|^2 + |a_c| \|\eta\|_{r+1,3q/4} + \epsilon^r \|\eta\|_{r+1,3q/4}^2) \]
Using the inductive hypothesis (6.15) gives:
\[ |a_c| \leq C_{r+1} (\epsilon^{r+1} + C_r \epsilon^{r+1} + C_r^2 \epsilon^{r+1} + C_r^2 \epsilon^2 \epsilon^{r+1} + C_r^2 \epsilon^{r+2}) \leq C_{r+1} \epsilon^{r+1}. \]
Thus we have established (6.15) with for \( r + 1 \) and we are done.

6.6. The main result. Summing up, we have proven our main result, stated here in full technicality.

**Theorem 16.** For all \( w > 1 \) there exists \( \bar{\epsilon} > 0 \) and \( \bar{q} > 0 \) such that the following holds for all \( \epsilon \in (0, \bar{\epsilon}) \).

(i) There exists \( \eta \in \cap_{r>0} (E_q^r \times O_q^r) \) and \( a_c \in \bar{a}_0, a_0 \) such that
\[ \theta(X) = \theta_c(X) := \sigma(X) + \eta_c(X) + a_c \varphi_c^\alpha(X) \]
solves (2.27).
(ii) For all \( r \geq 0 \) there exists \( C_r > 0 \) such that, for all \( \epsilon \in (0, \bar{\epsilon}) \):
\[ \|\eta_c\|_{r,q} \leq C_r \epsilon \quad \text{and} \quad |a_c| \leq C_r \epsilon^r. \]
(iii) \( \theta_c \) is unique in the sense that \( \eta_c \) and \( a_c \) are the only choices for which \( \theta_c \) is a solution of (2.27) and the estimates in (ii) hold.

**Remark 13.** The uniqueness result above does not rule out two interesting possibilities. The first is that there could be a different choice for \( \eta \) and a where \( \eta \in E_q^1 \times O_q^1 \) with \( q \in [0, \bar{q}) \). That is, \( \eta \to 0 \) at infinity at a rate slower than \( e^{-q|X|} \). We consider this to be unlikely; our conjecture is that the solution is in fact unique in the class of \( L^2 \times L^2 \) functions.

The other possibility is there are solutions of (2.27) which converge to \( a \varphi_c^\alpha(X \pm X_0) \) as \( X \to \pm \infty \), for some \( X_0 \in \mathbb{R} \). That is to say, the solution \( \theta \) converges to a phase-shifted member of the family of periodic solutions. This almost certainly will happen; the analogous result is shown to be true for gravity-capillary waves in [Bea91] and [Sun91] and the singularly perturbed KdV-type equation studied in [AT92]. To prove such a result can be achieved (following [AT92]) by making an adjustment to Beale’s ansatz (5.1). Specifically, replacing \( a \varphi_c^\alpha(X) \) with \( a \varphi_c^\alpha(X + \text{sgn}(X)X_0)\Xi(X) \) where \( \Xi(X) \) is a smooth positive \( C^\infty \) function which is zero at \( X = 0 \) and exactly equal to one for \( |X| \) large. Obviously this generates more than a few extra terms in (6.2) and complications in proving estimates down the line!

Theorem 16 implies, after undoing all the changes of variables that led from (1.3) to (2.27):

**Corollary 17.** For all \( w > 1 \) there exists \( \bar{\epsilon} > 0 \) and \( \bar{q} \) such that the following holds for all \( \epsilon \in (0, \bar{\epsilon}) \). Let \( c_\epsilon := \sqrt{r^2_w + \epsilon^2} \). There is a solution of (1.3) of the form
\[ r(j, t) = \frac{3}{4} \epsilon^2 (1 + w) \text{sech}^2 \left( \frac{\epsilon}{\sqrt{\alpha_w}} (j + c_\epsilon t) \right) + v_\epsilon^j (\epsilon (j + c_\epsilon t)) + p_\epsilon^j (j + c_\epsilon t) \]
where:

(i) \( v_{j+2}^j(X) = v_j^j(X) \) and \( p_{j+2}^j(X) = p_j^j(X) \) for all \( j \in \mathbb{Z} \) and \( X \in \mathbb{R} \).

(ii) For all \( r \geq 0 \) we have \( \|v_1^j\|_{H^q} + \|v_2^j\|_{H^q} \leq Cr^{-3} \). \( C_r > 0 \) depends only on \( r \) and \( w \) and not on \( \epsilon \).

(iii) \( p_1^j \) and \( p_2^j \) are periodic with period \( P_\epsilon \in I_w \) where \( I_w \) is a closed bounded subset of \( \mathbb{R}^+ \). \( I_w \) depends only on \( w \) and not on \( \epsilon \).

(iv) For all \( r \geq 0 \) we have \( \|p_1^j\|_{W^{r,\infty}} + \|p_2^j\|_{W^{r,\infty}} \leq Cr^{-r} \). \( C_r > 0 \) depends only on \( r \) and \( w \) and not on \( \epsilon \).

It is this corollary which is paraphrased nontechnically in Theorem 1.

7. Basic estimates

7.1. Estimates on \( \sigma \). Since \( \sigma(X) = \sigma_0 \sech^2(2q_0X) \), for all \( r \geq 0 \) there exists \( C_r > 0 \) such that

\[
\|\sigma\|_{r,q} = \|\sigma\|_{r,q} \leq C_r
\]

holds for all \( q \in [0, q_0] \). In fact \( \sigma \) is in \( H^q \) for all \( q \in [0, 2q_0] \), but by restricting the interval for \( q \) we can ensure that the constant \( C_r \) does not depend on \( q \). The constant does depend on \( r \), of course. Obviously it does not depend on \( \epsilon \) since \( \sigma \) does not.

7.2. Estimates for \( a\varphi_\epsilon^a \). The estimates for \( \varphi_\epsilon^a \) in Theorem 5 are valid for rescaled versions which are \( 2\pi \)-periodic. They are not scaled in this way when they appear in the expressions \( j_n \) and \( l_n \) and so we need to “translate” the estimates from Theorem 6. The chief difficulty here—which is in fact one of the chief difficulties in the whole argument—is that the frequency of \( \varphi_\epsilon^a \) depends on \( a \). This frequency mismatch will ultimate lead to the loss of spatial decay in the Lipschitz estimates 6.2. Here is the result.

Lemma 18. For all \( r \geq 0 \) there exists \( C_r > 0 \) such that for all \( \epsilon \in (0, 1) \) and \( a, \dot{a} \in [-a_0, a_0] \) we have

\[
\|\varphi_\epsilon^a\|_{W^{r,\infty}} + \|J_2^a\varphi_\epsilon^a\|_{W^{r,\infty}} \leq C_r \epsilon^{-r}
\]

and, for all \( X \in \mathbb{R} \),

\[
|\partial_X^r J_2^a(\varphi_\epsilon^a - \varphi_\epsilon^a)| \leq C_r \epsilon^{-r}|a - \dot{a}|(1 + |X|).
\]

Proof. The estimate follows directly from the estimates in Theorem 6 the fact that \( J_2^a(k) \) is uniformly bounded and the fact that \( K_\epsilon = O(1/\epsilon) \). We skip the details and instead focus on (7.3). We make the decomposition

\[
\varphi_\epsilon^a(X) - \varphi_\epsilon^a(X) = \Delta_1 + \Delta_2 + \Delta_3
\]

where

\[
\Delta_1 := \nu(K_\epsilon^a X) - \nu(K_\epsilon^a X), \quad \Delta_2 := \psi_\epsilon^a(K_\epsilon^a X) - \psi_\epsilon^a(K_\epsilon^a X)
\]

and \( \Delta_3 := \psi_\epsilon^a(K_\epsilon^a X) - \psi_\epsilon^a(K_\epsilon^a X) \).
We start with $J_2^s \Delta_1$. Since $J_2^s \nu e^{i\omega X} = [\tilde{J}_2(\epsilon X)] \nu e^{i\omega X}$ and since $\nu(X) = \sin(X) j$, we see

$$J_2^s \nu(\omega X) = \frac{1}{2i} \left[ \tilde{J}_2(\epsilon X) j \right] e^{i\omega X} - \frac{1}{2i} \left[ \tilde{J}_2(-\epsilon X) j \right] e^{-i\omega X}. \tag{7.5}$$

Thus

$$J_2^s \Delta_1 = \frac{1}{2i} \left[ \tilde{J}_2(\epsilon X) j \right] e^{i\epsilon X} - \frac{1}{2i} \left[ \tilde{J}_2(-\epsilon X) j \right] e^{-i\epsilon X}.$$ 

(7.6)

We add a lot of zeros and do a lot of rearranging to get:

$$J_2^s \Delta_1 = \frac{1}{2i} \left[ \left( \tilde{J}_2(\epsilon X) - \tilde{J}_2(-\epsilon X) \right) j \right] e^{i\epsilon X} + \frac{1}{2i} \left[ \tilde{J}_2(\epsilon X) j \right] \left( e^{i\epsilon X} - e^{i\epsilon X} \right)$$

$$+ \frac{1}{2i} \left[ \left( \tilde{J}_2(-\epsilon X) - \tilde{J}_2(-\epsilon X) \right) j \right] e^{-i\epsilon X} + \frac{1}{2i} \left[ \tilde{J}_2(-\epsilon X) j \right] \left( e^{-i\epsilon X} - e^{-i\epsilon X} \right).$$

We know from Corollary 3 that $\tilde{J}_2(k)$ is analytic and, since it is periodic for $k \in \mathbb{R}$, globally Lipschitz on $\mathbb{R}$. Thus we can estimate the term in the first line as

$$\left| \frac{1}{2i} \left[ \left( \tilde{J}_2(\epsilon X) - \tilde{J}_2(-\epsilon X) \right) j \right] e^{i\epsilon X} \right| \leq C |K^a - K^\alpha|.$$

The uniform Lipschitz estimate (4.4) for $K^a$ in Theorem 6 then gives

$$\left| \frac{1}{2i} \left[ \left( \tilde{J}_2(\epsilon X) - \tilde{J}_2(-\epsilon X) \right) j \right] e^{i\epsilon X} \right| \leq C |a - \ddot{a}|.$$

Exactly the same reasoning leads to the following estimate on the third line:

$$\left| \frac{1}{2i} \left[ \left( \tilde{J}_2(-\epsilon X) - \tilde{J}_2(-\epsilon X) \right) j \right] e^{-i\epsilon X} \right| \leq C |a - \ddot{a}|.$$

To estimate the second line of (7.6), first we use the fact that $\tilde{J}_2(k)$ is uniformly bounded for $k \in \mathbb{R}$:

$$\left| \frac{1}{2i} \left[ \tilde{J}_2(\epsilon X) j \right] \left( e^{i\epsilon X} - e^{i\epsilon X} \right) \right| \leq C \left| e^{i\epsilon X} - e^{i\epsilon X} \right|.$$

Then we use the global Lipschitz estimate for the complex exponential: $|e^{iy} - e^{iy'}| \leq 2|y - y'|$ for $y, y' \in \mathbb{R}$. This gives

$$\left| \frac{1}{2i} \left[ \tilde{J}_2(\epsilon X) j \right] \left( e^{i\epsilon X} - e^{i\epsilon X} \right) \right| \leq C \left| K^a X - K^\alpha X \right|.$$
In exactly the same fashion we can estimate the term in the fourth line to get:

\[
\left| \frac{1}{2i} \left[ \tilde{J}_2(-\epsilon \tilde{K}^a \epsilon) \right] e^{-i\tilde{K}^a \epsilon X} - e^{-i\tilde{K}^a \epsilon X} \right| \leq C |a - \tilde{a}| |X|.
\]

Thus all together we have:

\[(7.7) \quad |J^\epsilon_2 \Delta_1(X)| \leq C_\epsilon |a - \tilde{a}| + C |a - \tilde{a}| |X| \leq C |a - \tilde{a}| (1 + |X|).
\]

We also want to estimate \( \partial_X J^\epsilon_2 \Delta_1 \). Each term in \( J^\epsilon_2 \Delta_1 \) contains \( e^{i\tilde{K}^a \epsilon X} \) or \( e^{i\tilde{K}^a \epsilon X} \) and thus taking \( r \) derivatives with respect to \( X \) will produce additional terms like \( (K^a)^r \). We know that \( K^a_0 = O(1/\epsilon) \) and the Lipschitz estimate \( (4.4) \) for \( K^a_0 \) implies that \( K^a_0 = O(1/\epsilon) \) as well. Thus \( (K^a)^r = O(\epsilon^{-r}) \). This results in the following estimate:

\[(7.8) \quad |\partial_X J^\epsilon_2 \Delta_1(X)| \leq C_{\epsilon} \epsilon^{-r} |a - \tilde{a}| (1 + |X|).
\]

Now look at \( J^\epsilon_2 \Delta_2 \). We know that \( \psi^a_e(y) \) is \( 2\pi \)-periodic and, moreover, smooth in \( X \). Thus we can expand it in its Fourier series: \( \psi^a_e(y) = \sum_{j \in \mathbb{Z}} \hat{\psi}^a_e(j)e^{ijy} \). Noting that both terms in \( \Delta_2 \) are periodic with the same frequency, we see that:

\[\Delta_2(X) = \sum_{j \in \mathbb{Z}} (\hat{\psi}^a_e(j) - \hat{\psi}^b_e(j))e^{ij\tilde{K}^a \epsilon X}.
\]

Applying \( J^\epsilon_2 \) gives

\[J^\epsilon_2 \Delta_2(X) = \sum_{j \in \mathbb{Z}} J_2(\epsilon j \tilde{K}^a \epsilon) (\hat{\psi}^a_e(j) - \hat{\psi}^b_e(j))e^{ij\tilde{K}^a \epsilon X}.
\]

Since \( \psi^a_e \) is smooth, classical Fourier series estimates give

\[\left| \hat{\psi}^a_e(j) - \hat{\psi}^b_e(j) \right| \leq C_{\epsilon} (1 + |j|^r)^{-1} \left| \psi^a_e - \psi^b_e \right|_{C^r_{\text{per}}} \]

where we make the \( r \) as large as we wish. The uniform Lipschitz estimate \( (4.4) \) for \( \psi^a_e \) in Theorem \( \epsilon \) then implies:

\[\left| \hat{\psi}^a_e(j) - \hat{\psi}^b_e(j) \right| \leq C (1 + j^2)^{-1} |a - \tilde{a}|.
\]

Thus, since \( \{(1 + j^2)\}_{j \in \mathbb{Z}} \) is summable,

\[(7.9) \quad |J^\epsilon_2 \Delta_2(X)| \leq C |a - \tilde{a}|.
\]

As above if we differentiate \( J^\epsilon_2 \Delta_2 \) \( r \) times with respect to \( X \) (each of which produces one power of \( K^a_0 \)) and repeat the same steps we find:

\[(7.10) \quad |\partial_X^r J^\epsilon_2 \Delta_2(X)| \leq C_{\epsilon} \epsilon^{-r} |a - \tilde{a}|.
\]

To handle \( \Delta_3 \) is basically a combination of how we dealt with \( \Delta_1 \) and \( \Delta_2 \). Using the Fourier expansion for \( \psi^a_e \) from above we see that:

\[J^\epsilon_2 \Delta_3 = \sum_{j \in \mathbb{Z}} \left[ J_2(\epsilon j \tilde{K}^a \epsilon) \hat{\psi}^a_e(j) e^{ij\tilde{K}^a \epsilon X} - J_2(\epsilon j \tilde{K}^a \epsilon) \hat{\psi}^b_e(j) e^{ij\tilde{K}^a \epsilon X} \right].
\]
Adding zero and rearranging terms gives:
\[
J_2^r \Delta_3 = \sum_{j \in \mathbb{Z}} [\tilde{J}_2(\epsilon j K^a \hat{\psi}^\beta(j))] (e^{ijK^a X} - e^{ijK^\beta X})
\]
\[+ \sum_{j \in \mathbb{Z}} \left[ (\tilde{J}_2(\epsilon j K^a \hat{\psi}^\beta(j)) - e^{ijK^\beta X} \right].
\]

Using (as we did when estimating \(\Delta_1\) above) the fact that \(\tilde{J}_2\) and \(e^{ijy}\) are globally Lipschitz together with the estimate \(|K^a - K^\beta| \leq C|a - \hat{a}|\) implied by Theorem 6, we have
\[
|J_2^r \Delta_3(X)| \leq C|a - \hat{a}|(1 + |X|) \sum_{j \in \mathbb{Z}} |\hat{\psi}^\beta(j)| |j|.
\]

Next (as we did when estimating \(\Delta_2\)) we use the rapid decay of the Fourier coefficients of \(\psi^\beta\) to conclude that \(\sum_{j \in \mathbb{Z}} |\hat{\psi}^\beta(j)| |j| \leq C\). This gives
\[
|J_2^r \Delta_3(X)| \leq C|a - \hat{a}|(1 + |X|).
\]

In exactly the same fashion, we can establish
\[
|\partial_X^r J_2^r \Delta_3| \leq C_r e^{-r}|a - \hat{a}|(1 + |X|).
\]
Thus all together we have shown (7.3).

7.3. Product estimates. Since our nonlinearity is quadratic we need good estimates for products of functions. In particular we need estimates that keep track of decay rates. First we note the famous Sobolev inequality \(\|f\|_{L^\infty(\mathbb{R})} \leq \|f\|_{H^1(\mathbb{R})}\) implies
\[
\|\cosh(q \cdot f)\|_{W^{r,\infty}} \leq C_r \|f\|_{r+1,q}
\]
for all \(r \geq 0\) and \(q \geq 0\). Then we have:

**Lemma 19.** For all \(r \geq 0\) there exists \(C_r > 0\) such that following estimates hold for all \(q, q' \geq 0\). If \(q \geq q'\) then
\[
\|fg\|_{r,q} \leq C_r \|f\|_{r,q'} \cosh(|q - q'| \cdot) g\|_{W^{r,\infty}}.
\]

If \(q \leq q'\) then
\[
\|fg\|_{r,q} \leq C_r \|f\|_{r,q'} \sech(|q' - q'| \cdot) g\|_{W^{r,\infty}}.
\]
Lastly, if \(r \geq 1\) and \(0 \leq q' < q:\)
\[
\|fg\|_{r,q} \leq C_r \|f\|_{r,q'} \|g\|_{r,q - q'}.
\]

**Proof.** Definitionally \(\|fg\|_{r,q} = \|\cosh(q \cdot) f g\|_{H^r}\). We multiply by one inside as follows:
\[
\|fg\|_{r,q} = \|\cosh(q \cdot) \sech(q \cdot) \cosh((q' - q) \cdot) (\cosh(q' \cdot) f) \sech((q' - q) \cdot) g\|_{H^r}.
\]
The estimate \(\|uv\|_{H^r} \leq C\|u\|_{H^r} \|v\|_{W^{r,\infty}}\) is well-known and using it here gives:
\[
\|fg\|_{r,q} \leq \|\cosh(q \cdot) \sech(q \cdot) \cosh((q' - q) \cdot) \|_{W^{r,\infty}} \|\cosh(q' \cdot) f\|_{H^r} \|\sech((q' - q) \cdot) g\|_{W^{r,\infty}}.
\]
Routine calculus methods shows that the condition \(q \leq q'\) implies
\[
\|\cosh(q \cdot) \sech(q \cdot) \cosh((q' - q) \cdot)\|_{W^{r,\infty}} \leq C_r
\]
for a constant $C_r$ which depends only on $r$. This gives (7.15).

If instead we multiply by one inside like:

$$\|fg\|_{r,q} = \| (\cosh(q') \text{sech}(q') \text{sech}(q' - q)) (\cosh(q')f)(\cosh((q' - q)g)) \|_{H^r}.$$  

then the estimate

$$\| \cosh(q') \text{sech}(q') \text{sech}(q' - q) \|_{W^{r,\infty}} \leq C_r,$$

which holds when $q \geq q'$ gives (7.14).

The remaining estimate (7.16) follows from (7.14) and (7.13). □

**Remark 14.** Note that we sometimes refer to (7.15) as a “decay borrowing” estimate, since it allows growth in $g$ at the expense of extra decay in $f$. On the other hand, the estimates (7.14) and (7.16) require both $f$ and $g$ to decay.

### 7.4. Estimates for $A$

The next result confirms the earlier claim that $A$ is invertible on even functions.

**Proposition 20.** There exists $q_1 > 0$ such that $A$ is a bijection from $E^r_q$ to itself for all $q \in [0, q_1]$ and $r \geq 1$. Additionally, for each $r \geq 1$, there exists $C > 0$ such that

(7.17) $$\|A^{-1}f\|_{r,q} \leq C\|f\|_{r,q}$$

for all $q \in [0, q_1]$ and $f \in E^r_q$.

**Proof.** This is shown to be true in [FP99] for the special case when $q = 0$. The extension to $q > 0$ can be achieved by using the now classical technique of operator conjugation [PW94]. We omit the details. □

### 7.5. Estimates for $\iota_\epsilon$

The following estimate is a version of the famous Riemann-Lebesgue Lemma:

**Lemma 21.** There exists $C > 0$ such that for any $f \in H^r_q$, with $r \geq 0$, $q > 0$ and $|\omega| \geq 1$ we have:

$$\left| \int_{\mathbb{R}} f(x)e^{i\omega x} dx \right| \leq \frac{C}{\omega^r \sqrt{q}} \|f\|_{r,q}.$$  

**Proof.** Assume that $f$ is a Schwartz class function and $|\omega| \geq 1$. Then integration by parts gives:

$$I := \left| \int_{\mathbb{R}} f(x)e^{i\omega x} dx \right| = \left| \int_{\mathbb{R}} f(x) \frac{1}{\omega^r} \frac{d^r}{dx^r} [e^{i\omega x}] dx \right| = |\omega|^{-r} \left| \int_{\mathbb{R}} f^{(r)}(x)e^{i\omega x} dx \right|.$$  

Next we use the triangle inequality to get:

$$I \leq |\omega|^{-r} \int_{\mathbb{R}} |f^{(r)}(x)| dx.$$  

Multiplication by one and Cauchy-Schwartz yields:

$$I \leq |\omega|^{-r} \int_{\mathbb{R}} |f^{(r)}(x)| \cosh(qx) \text{sech}(qx) dx \leq |\omega|^{-r} \|f^{(r)}\|_{0,q} \|\text{sech}(q\cdot)\|_{L^2}.$$  

Of course $\|f^{(r)}\|_{0,q} \leq \|f\|_{r,q}$ and $\|\text{sech}(q\cdot)\|_{L^2} = q^{-1/2} \|\text{sech}(\cdot)\|_{L^2}$. This establishes the conclusion for Schwartz class functions. A classical density argument completes the proof. □
Since $K_\epsilon = \mathcal{O}(1/\epsilon)$, Lemma 21 implies

\begin{equation}
|\epsilon_\epsilon[f]| \leq C\frac{\epsilon^r}{\sqrt{q}} \|f\|_{r,q}.
\end{equation}

7.6. Estimates for Fourier multipliers. The following result of Beale (specifically, Lemma 3 of [Bea91]) will be used repeatedly.

**Theorem 22.** Suppose that $\tilde{\mu}(z)$ is a complex valued function which has the following properties:

(i) $\tilde{\mu}(z)$ is meromorphic on the closed strip $\Sigma_q = \{|\Im z| \leq q\} \subset \mathbb{C}$ where $q > 0$;
(ii) there exists $m \geq 0$ and $c_\ast, \zeta_\ast > 0$ such that $|z| > \zeta_\ast$ and $z \in \Sigma_q$ imply $|\tilde{\mu}(z)| \leq c_\ast/|\Re z|^m$;
(iii) the set of singularities of $\tilde{\mu}(z)$ in $\Sigma_q$ (which we denote $P_\mu$) is finite and, moreover, is contained in the interior $\Sigma_q$;
(iv) all singularities of $\tilde{\mu}(z)$ in $\Sigma_q$ are simple poles.

Let

$$
U_{\mu,q}^r := \left\{ f \in H_q^r : z \in P_\mu \implies \hat{f}(z) = 0 \right\}.
$$

Then the Fourier multiplier operator $\mu$ with symbol $\tilde{\mu}$ is a bounded injective map from $U_{\mu,q}^r$ into $H_q^{r+m}$. Additionally, for all $m' \in [0,m]$, we have the estimates:

\begin{equation}
\|\mu f\|_{r+m',q} \leq C_{\mu,m'}\|f\|_{r,q}
\end{equation}

where

\begin{equation}
C_{\mu,m'} := \sup_{k \in \mathbb{R}} \left| (1 + |k|^2)^{m'/2} \tilde{\mu}(k \pm iq) \right|.
\end{equation}

The first consequence of this is:

**Corollary 23.** For all $w > 1$ we have the following.

(i) There exists $C > 0$ and $\tau_2 > 0$ such that the following holds for all $\tau \in (0,\tau_2]$ and $r \in \mathbb{R}$. The operators $\lambda_\pm$ are bounded linear maps from $H_q^r \to H_q^r$. Likewise, $J_1$ and $J_2$ are bounded maps from $H_q^r \times H_q^r \to H_q^r \times H_q^r$. We have the estimates:

\begin{equation}
\|\lambda_\pm f\|_{r,\tau} + \|\lambda_- f\|_{r,\tau} \leq C\|f\|_{r,\tau} \quad \text{and} \quad \|J_1 f\|_{r,\tau} + \|J_2 f\|_{r,\tau} \leq C\|f\|_{r,q}.
\end{equation}

(ii) There exists $C > 0$, $\epsilon_1 \in (0,1)$ and $q_2 > 0$ such that the following holds for all $q \in [0,q_2], r \in \mathbb{R}$ and $\epsilon \in [0,\epsilon_1]$. The operators $\lambda^\pm$ are bounded linear maps from $H_q^r \to H_q^r$. Likewise $J_1^\epsilon$ and $J_2^\epsilon$ are bounded maps from $H_q^r \times H_q^r \to H_q^r \times H_q^r$. We have the estimates:

\begin{equation}
\|\lambda^\pm f\|_{r,q} + \|\lambda_-^\mp f\|_{r,q} \leq C\|f\|_{r,q} \quad \text{and} \quad \|J_1^\epsilon f\|_{r,q} + \|J_2^\epsilon f\|_{r,q} \leq C\|f\|_{r,q}.
\end{equation}

We do not provide the details of the proof. All the operators have symbols which are bounded analytic functions on strips (Lemma 2, Corollary 3) and thus everything follows directly from Theorem 22.
7.7. Estimates for $\chi_\epsilon$. Restrict $q \in [0, q_2]$. Using the definition of $\chi_\epsilon$ and the triangle inequality gives $\|\chi_\epsilon\|_{r,q} \leq \|\lambda_+ J_1^r (J_2^0 \sigma \cdot J_2^s \nu_\epsilon)\|_{r,q}$. Corollary 23 tells us that for $\lambda_+^r$ and $J_1^r$ are operators from $H^r_q$ to itself which are bounded independently of $\epsilon$. Thus $\|\chi_\epsilon\|_{r,q} \leq C \|J_2^0 \sigma \cdot J_2^s \nu_\epsilon\|_{r,q}$. Using the product inequality (7.14) gives $\|\chi_\epsilon\|_{r,q} \leq C \|J_2^0 \sigma\|_{r,q}\|J_2^s \nu_\epsilon\|_{W^{r,\infty}}$. Using (7.1) and (7.2) gives:

\[
(7.23) \quad \|\chi_\epsilon\|_{r,q} \leq C_r \epsilon^{-r}
\]

for any $r \geq 0$, $q \in [0, q_2]$ and $\epsilon \in (0, \epsilon_1]$.

7.8. Estimates for $\kappa_\epsilon$. A rather tedious computation shows the unsurprising result that $\chi_\epsilon(X)$ is an odd function of $X$; we omit it. Given this, we have

\[
\kappa_\epsilon = \iota_\epsilon[\chi_\epsilon] = 2\pi i \bar{\chi}_\epsilon(K_\epsilon).
\]

Since $\chi_\epsilon(X) = \lambda_+^r J_1^r(J_2^0 \sigma \cdot J_2^s \nu_\epsilon) \cdot j$ and $\lambda_+^r$ and $J_1^r$ are Fourier multipliers we have

\[
\bar{\chi}_\epsilon(K_\epsilon) = \bar{\lambda}_+(\epsilon K_\epsilon) \left( \bar{J}_1(\epsilon K_\epsilon) \tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) \right) \cdot j.
\]

By definition

\[
\tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) = \frac{1}{2\pi} \int_{\mathbb{R}} J_2^0 \sigma(X) J_2^s \nu_\epsilon(X) e^{-i K_\epsilon X} dX.
\]

and

\[
J_2^0 \sigma(X) = 2(1 + w)\sigma(X) \left( \begin{array}{c} 1 \\ 1 \end{array} \right).
\]

Thus

\[
\tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) = \frac{1 + w}{\pi} \int_{\mathbb{R}} \sigma(X) J_2^s \nu_\epsilon(X) e^{-i K_\epsilon X} dX.
\]

Since $\nu_\epsilon(X) = (2i)^{-1}[e^{i K_\epsilon X} - e^{-i K_\epsilon X}]j$ and $J_2^s$ is a Fourier multiplier, the last becomes

\[
\tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) = \frac{1 + w}{2\pi i} \int_{\mathbb{R}} \sigma(X) \left( \bar{J}_2(\epsilon K_\epsilon) j e^{i K_\epsilon X} - \bar{J}_2(-\epsilon K_\epsilon) j e^{-i K_\epsilon X} \right) e^{-i K_\epsilon X} dX.
\]

After rearranging terms in this we have

\[
\tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) = \frac{1 + w}{2\pi i} \left( \int_{\mathbb{R}} \sigma(X) dX \right) \left( \bar{J}_2(\epsilon K_\epsilon) j \right)
\]

\[
- \frac{1 + w}{2\pi i} \left( \int_{\mathbb{R}} \sigma(X) e^{-2\epsilon K_\epsilon X} dX \right) \left( \bar{J}_2(-\epsilon K_\epsilon) j \right).
\]

Recalling the definition of the Fourier transform, the above can be written as:

\[
\tilde{\mathcal{F}}[J_2^0 \sigma \cdot J_2^s \nu_\epsilon](K_\epsilon) = -i(1 + w)\tilde{\sigma}(0) \left( \bar{J}_2(\epsilon K_\epsilon) j \right) + i(1 + w)\tilde{\sigma}(2K_\epsilon) \left( \bar{J}_2(-\epsilon K_\epsilon) j \right).
\]

Since $\sigma(X) > 0$ for all $X$, we have $\tilde{\sigma}(0) > 0$. Since $\sigma(X)$ is analytic and square integrable, classical Fourier analysis can be used to show that there is a constant $C > 0$ for which $|\tilde{\sigma}(k)| \leq C e^{-C|k|}$. Since $K_\epsilon = O(1/\epsilon)$ this means that $|\tilde{\sigma}(2K_\epsilon)| \leq C e^{-C/\epsilon}$. That is to say, it is exponentially small in $\epsilon$. Thus we have shown that

\[
(7.24) \quad |\kappa_\epsilon - \kappa_\epsilon^*| \leq C e^{-C/\epsilon}
\]
where

$$
\kappa^*_\epsilon := 2\pi(1 + w)\tilde{\sigma}(0)\tilde{\lambda}_+(\epsilon K_\epsilon)[\tilde{J}_1(\epsilon K_\epsilon)\tilde{J}_2(\epsilon K_\epsilon)] \cdot j.
$$

It has been some time, but \( \tilde{J}_1 = \tilde{J}_2^{-1} \). Thus

$$
\kappa^*_\epsilon = 2\pi(1 + w)\tilde{\sigma}(0)\tilde{\lambda}_+(\epsilon K_\epsilon).
$$

We also saw in Lemma 2 that \( 2\omega < \tilde{\lambda}_+(k) \) for all \( k \in \mathbb{R} \). Thus \( \kappa^*_\epsilon \) is strictly bounded away from zero. This, with (7.24), demonstrates that there is constant \( C > 0 \) and \( \epsilon_2 \in (0, 1) \) for which

$$
(7.25) \quad |\kappa_\epsilon| \geq C \quad \text{for all } \epsilon \in (0, \epsilon_2).
$$

7.9. Estimates and solvability conditions for \( T_\epsilon \). Theorem 22 allows us establish the features of \( T_\epsilon \) described in the previous section. In particular we have:

Lemma 24. There exists \( \epsilon_3 \in (0, 1) \) and \( q_3 > 0 \) such that for all \( q \in (0, q_3] \) there exists \( C_q > 0 \) such that for all \( \epsilon \in (0, \epsilon_2] \) the following hold.

(i) There exists \( f \in H^{r+2}_q \) such that \( T_\epsilon f = g \in H^r_q \) if and only if \( \tilde{g}(\pm K_\epsilon) = 0 \).

(ii) If \( \tilde{g}(\pm K_\epsilon) = 0 \) then the solution \( f \) is unique. We denote the solution by \( f = T_\epsilon^{-1}g \).

(iii) If \( \tilde{g}(\pm K_\epsilon) = 0 \) then the solution \( f \) satisfies the estimates

$$
(7.26) \quad \|f\|_{r+q,2} = \|T_\epsilon^{-1}g\|_{r,q} \leq \frac{C_q}{\epsilon^{j+1}}\|g\|_{r,q} \quad \text{where } j = 0, 1 \text{ or } 2.
$$

(iv) For all \( g \in O^r_q \) there exists a unique \( f \in O^{r+2}_q \) such that \( T_\epsilon f = g - \frac{1}{\kappa_\epsilon}[g]_\epsilon \). We denote the solution by \( f = P_\epsilon g \).

(v) We have the estimates

$$
(7.27) \quad \|P_\epsilon g\|_{r+q,2} \leq \frac{C_q}{\epsilon^{j+1}}\|g\|_{r,q} \quad \text{where } j = 0, 1 \text{ or } 2.
$$

(vi) Lastly,

$$
C_q \to \infty \quad \text{as } q \to 0^+.
$$

To prove this, we need the following result, which is proved in Section 9.

Lemma 25. Let

$$
\tilde{\xi}_\epsilon(z) := -c^2z^2 + \tilde{\lambda}_+(z).
$$

There exists \( \delta > 0 \), \( \ell_0 > 0 \), \( R > 0 \), \( \tau_3 > 0 \) and \( C > 0 \) such that the following hold when \( |c - c_w| \leq \delta \) and \( |\tau| \leq \tau_3 \).

(i) \( \tilde{\xi}_\epsilon(z) \) is analytic on the closed strip \( \Sigma_{\tau_3} := \{|3z| \leq \tau_3\} \) and is even.

(ii) \( \tilde{\xi}_\epsilon(z) \geq C|z|^2 \) for \( |z| \geq R \).

(iii) If \( j = 0, 1 \) or \( 2 \) then

$$
(7.28) \quad \inf_{k \in \mathbb{R}} (1 + k^2)^{-j/2}\tilde{\xi}_\epsilon(k + i\tau) \geq C|\tau|.
$$
Proof. (of Lemma 24) Suppose that $\epsilon \in (0, \epsilon_3)$ where $\epsilon_3 := \min(1, \epsilon_1, \epsilon_2, \delta)$ and $q \in (0, q_3] := \min(\tau_1, \tau_2, \tau_3, q_0, q_1, q_2)$.

The map $T_\epsilon$ can be viewed as a Fourier multiplier with symbol

$$\tilde{T}_\epsilon(Z) = \frac{\tilde{\epsilon}}{\sqrt{c_0^2 + \epsilon^2}}(\epsilon Z).$$

From Part (vi) of Lemma 2 and the estimate (7.28) we know that that $\tilde{T}_\epsilon(Z)$ has exactly two zeros, both real and simple, at $Z = \pm K_\epsilon = \pm \epsilon k / \sqrt{c_0^2 + \epsilon^2}$. Thus we see that if $f \in H^{r+2}_q$, with $0 < q \leq q_3$, then $\tilde{T}_\epsilon(\pm K_\epsilon)\tilde{f}(\pm K_\epsilon) = 0$; this is “only if” of Part (i).

This is also equivalent to the condition that $i_\epsilon[g] = 0$ discussed above, if $g$ is odd.

And so we see that $1/\tilde{T}_\epsilon(Z)$ has two simple poles at $P_\epsilon = \{ \pm K_\epsilon \}$ and no other poles in $\Sigma_q$ when $q \in (0, q_3]$. Similarly, Part (ii) of Lemma 22 indicates that $1/|\tilde{T}_\epsilon(Z)| \leq C|\Re Z|^{-2}$ for $|Z|$ large enough. Thus $1/\tilde{T}_\epsilon(Z)$ satisfies all the conditions of the multiplier in Theorem 22 for any decay rate $q \in (0, q_3]$, $m = 2$ and pole set $\{ \pm K_\epsilon \}$.

And so we have a well-defined map $T_\epsilon^{-1}$ from $U_{\epsilon,q} := \{ g \in H^r_q : \tilde{g}(\pm K_\epsilon) = 0 \}$ into $H^{r+2}_q$ which inverts $T_\epsilon$. Specifically $T_\epsilon T_\epsilon^{-1}$ is the identity on $U_{\epsilon,q}$. Putting $f = T_\epsilon^{-1}$ gives the other implication in Part (i). The uniqueness of Part (ii) follows from the injectivity of $T_\epsilon$.

The estimates (7.26) in Part (iii) follow from (7.19), (7.20) and the estimate in (7.28). Specifically, fix $q \in (0, q_3]$. The formula (7.20) tells that

$$\|	ilde{T}_\epsilon^{-1}g\|_{r+1,q} \leq C_{\epsilon,j}\|g\|_{r,q}$$

where $j = 0, 1$ or 2. Thus to get (7.26) we need to show that $C_{\epsilon,j} \leq C_q / \epsilon^{j+1}$.

Letting $k = \epsilon K$ we see:

$$C_{\epsilon,j} := \sup_{K \in \mathbb{R}} \left| (1 + |K|^2)^{j/2} \tilde{T}_\epsilon^{-1}(K + iq) \right|$$

Then we multiply by one on the inside and use elementary estimates to get:

$$C_{\epsilon,j} \leq \sup_{K \in \mathbb{R}} \left| (1 + |k/\epsilon|^2)^{j/2} \tilde{T}_\epsilon^{-1}(k + iq) \right| \leq \epsilon^{-j} \sup_{k \in \mathbb{R}} \left| (1 + k^2)^{j/2} \tilde{T}_\epsilon^{-1}(k + iq) \right|$$

Then we use (7.28) with $\tau = \epsilon q$ to get

$$C_{\epsilon,j} \leq C\epsilon^{-j}|\epsilon q|^{-1} = C|q|^{-1}\epsilon^{-j-1}.$$
To prove parts (iv) and (v) we first observe that $T_{\epsilon}$ (and therefore $T_{\epsilon}^{-1}$) maps odd functions to functions. For odd functions, a short computation shows that $\nu_\epsilon[g] = 2\pi i \tilde{g}(K_\epsilon)$. Thus

$$\mathfrak{F} \left[ g - \frac{1}{\kappa_\epsilon} \nu_\epsilon[g] \chi_\epsilon \right] (\pm K_\epsilon) = 0.$$ 

So we can apply parts (i)-(ii) to get Part (iv). The estimate in Part (v) is shown as follows. The Riemann-Lebesgue estimate (7.18) implies that $|\nu_\epsilon[g]| \leq C_q \epsilon^r \|g\|_{r,q}$. And so if we use this, the estimate in Part (iii), (7.23) and (7.25), we have:

$$\|P_\epsilon g\|_{r+J,q} \leq \frac{C_q}{\epsilon^{J+1}} \left\| g - \frac{1}{\kappa_\epsilon} \nu_\epsilon[g] \chi_\epsilon \right\|_{r+J,q} \leq \frac{C_q}{\epsilon^{J+1}} \left( \|g\|_{r,q} + |\nu_\epsilon[g]| \epsilon^r \right) \leq \frac{C_q}{\epsilon^{J+1}} \|g\|_{r,q}.$$

\[\square\]

7.10. **Symbol truncation estimates.** In this subsection we prove a series of results which give estimates the operator norm of things like $J^1_\epsilon - J^0_\epsilon$ when $\epsilon$ is small.

**Lemma 26.** Suppose that $\tilde{\mu}$ meets the hypotheses of Theorem 22 with $P_\mu = \{\epsilon\}$ and $m = 0$. (That is to say, $\tilde{\mu}$ is bounded.) Let $\tilde{\zeta}_n(z) := \tilde{\mu}(z) - \sum_{j=0}^n \tilde{\mu}_j z^j$ where the constants $\tilde{\mu}_j \in \mathbb{C}$ are the coefficients in the Maclaurin series of $\tilde{\mu}$. Then the Fourier multiplier operators $\tilde{\zeta}_n$ with symbols $\tilde{\zeta}_n$ are bounded from $H_q^{n+1}$ to $H_q^n$ and satisfy the estimate

$$\|\tilde{\zeta}_n f\|_{r,q} \leq C_n \|f^{(n+1)}\|_{r,q}.$$

The constant $C_n > 0$ is independent of $r$.

**Proof.** Within the radius of convergence of the Maclaurin series we have:

$$\tilde{\zeta}_n(z) = \sum_{j=n+1}^\infty \tilde{\mu}_j z^j = z^{n+1} \sum_{j=0}^\infty \tilde{\mu}_{j+n+1} z^j.$$

So if we put

$$\tilde{\nu}_n(z) = \tilde{\zeta}_n(z)/z^{n+1}$$

then clearly the singularity at $z = 0$ is removable. This implies that on any closed disk containing the origin and with radius smaller than the radius of convergence, $\tilde{\nu}(z)$ is analytic and bounded. Outside this disk, but within $\Sigma_q$, we have $\tilde{\nu}(z) = (\tilde{\mu}(z) - \sum_{j=0}^n \tilde{\mu}_j z^j)/z^{n+1}$. In this case, all of the functions on the right hand side are analytic. Moreover they are all bounded since $\tilde{\mu}(z)$ is bounded and $|z|$ is smallest on the boundary of the disk. In short, $\tilde{\nu}(z)$ meets the hypothesis of Theorem 22 on $\Sigma_q$ with an empty pole set, $m = 0$. Let $v$ be the operator associated to $\tilde{\nu}$. Observing that $\zeta_n f = \epsilon^i \nu_n f^{(n+1)}$ and applying the results of Theorem 22 finishes the proof. \[\square\]

This result implies the following:

**Lemma 27.** There exists $C > 0$ such that for $q \in [0, \tau_\epsilon]$ and $\epsilon \in (0,1)$ we have the following for all $r \geq 0$,

$$\|(J^1_\epsilon - J^0_1) u\|_{r,q} \leq C \epsilon \|u\|_{r+1,q} \quad \text{and} \quad \|(J^1_2 - J^0_2) u\|_{r,q} \leq C \epsilon \|u\|_{r+1,q}.$$

(7.29)
Proof. We prove the estimates for \( r = 0 \). That multipliers commute with derivatives will extend this case to the general. So

\[
\| (J_n^c - J_n^0) u \|_{0,q}^2 = \int_\mathbb{R} |(J_n^c - J_n^0) u(X)|^2 \cosh^2(qX) dX.
\]

If we let \( u^\epsilon(x) = u(\epsilon x) \) then the discussion in Remark 5 implies that

\[
\| (J_n^c - J_n^0) u \|_{0,q}^2 = \int_\mathbb{R} |(J_n^c - J_n^0) u^\epsilon(X/\epsilon)|^2 \cosh^2(qX) dX.
\]

We make the change of variables \( X = \epsilon x \) in the integral to get:

\[
\| (J_n^c - J_n^0) u \|_{0,q}^2 = \epsilon \int_\mathbb{R} |(J_n^c - J_n^0) u^\epsilon(x)|^2 \cosh^2(q\epsilon x) dX = \epsilon \| (J_n^c - J_n^0) u^\epsilon \|_{0,q}^2.
\]

Since \( q \in [0, \tau_2] \) and \( \epsilon \in (0, 1) \) we have \( q\epsilon \leq \tau_2 \). We know that \( \tilde{J}_2 \) is analytic on \( \Sigma_{\tau_2} \) from Corollary 3. Thus we can use Lemma 26 to get \( \| (J_n^c - J_n^0) u \|_{0,q}^2 \leq C\epsilon \| \partial_x u^\epsilon \|_{0,q}^2 \). A routine calculation shows that

\[
\| \partial_x u^\epsilon \|_{0,q}^2 = \| \partial_X u \|_{0,q}^2. \]

Thus we have the \( r = 0 \) estimates

\[
\| (J_n^c - J_n^0) u \|_{0,q} \leq C\epsilon \| u \|_{1,q}.
\]

\[ \square \]

7.11. Estimates for \( \varpi^\epsilon \). In this subsection we shall prove some useful estimates for \( \varpi^\epsilon \) and, in particular, show that it converges in the operator norm topology to \( \varpi^0 \) as \( \epsilon \to 0^+ \). This result is similar to one employed in [FP99] and stands in contrast to the results from the previous subsection where the approximation of \( J_j^\epsilon \) by \( J_j^0 \) comes at the cost of a derivative. We have:

**Lemma 28.** There exists \( C > 0 \), \( \epsilon_4 \in (0, 1) \) and \( q_4 > 0 \) such that following hold for all \( \epsilon \in [0, \epsilon_4] \) and \( q \in [0, q_4] \).

\( \varpi^\epsilon \) is a bounded map from \( H^r_q \) to \( H^{r+2}_q \), for any \( r \geq 0 \).

(i) For all \( r \geq 0 \) we have

\[ \| \varpi^\epsilon f \|_{r+2,q} \leq C\| f \|_{r,q}. \]

(ii) For all \( r \geq 0 \) we have

\[ \| \varpi^\epsilon - \varpi^0 \|_{r,q} \leq C\epsilon^2 \| f \|_{r,q}. \]

(iii) For all \( \omega > 1 \) we have

\[ \| \varpi^\epsilon (f e^{i\omega}) \|_{1,q} \leq C\omega^{-1} \| f \|_{2,q}. \]

To prove this we need the following result, which is proved in Section 9.

**Lemma 29.** There exists \( C > 0 \), \( \epsilon_4 \in (0, 1) \) and \( q_4 > 0 \) such that following hold for all \( \epsilon \in [0, \epsilon_4] \) and \( q \in [0, q_4] \).

\( \varpi^\epsilon(Z) \) is analytic and bounded in the strip \( \Sigma_q \).

(ii) \( |\varpi^\epsilon(Z)| \leq C/(1 + |Z|^2) \) for all \( Z \in \Sigma_q \).

(iii) \( |\varpi^\epsilon(Z) - \varpi^0(Z)| \leq C\epsilon^2 \) for all \( Z \in \Sigma_q \).
Proof. (Of Lemma 28) Parts (i)-(iii) of Lemma 28 follow from Parts (i)-(iii) of Lemma 29 and an application of Theorem 22. We spare the details.

Part (iv) is proven using an idea employed from [AT92]. Let $(1 - \alpha_w \partial_X^2)^{-1}(fe^{\omega X}) = g$. Equivalently, $\alpha_w g'' - g = -fe^{\omega X}$. Put $g_1 := g + \frac{1}{\alpha_w \omega^2}fe^{\omega X}$. Then

$$\alpha_w g'' - g_1 = \alpha_w g'' - g - \frac{1}{\alpha_w \omega^2}fe^{\omega X} + fe^{\omega X} + \frac{2i}{\omega}f'e^{\omega X} + \frac{1}{\omega^2}f''e^{\omega X}$$

$$= -\frac{1}{\alpha_w \omega^2}fe^{\omega X} + \frac{2i}{\omega}f'e^{\omega X} + \frac{1}{\omega^2}f''e^{\omega X}$$

or rather

$$g_1 = -(1 - \alpha_w \partial_X^2)^{-1}\left(-\frac{1}{\alpha_w \omega^2}fe^{\omega X} + \frac{2i}{\omega}f'e^{\omega X} + \frac{1}{\omega^2}f''e^{\omega X}\right)$$

$$= e^{-2\omega}0\left(-\frac{1}{\alpha_w \omega^2}fe^{\omega X} + \frac{2i}{\omega}f'e^{\omega X} + \frac{1}{\omega^2}f''e^{\omega X}\right).$$

Then we use Part (i) to conclude that

$$\|g_1\|_{2,q} \leq C\omega^{-1}\|f\|_{2,q}.$$ 

Next, naive estimates show that $\|fe^{\omega r}\|_{1,q} \leq C\omega\|f\|_{1,q}$. And since $(1 - \alpha_w \partial_X^2)^{-1}(fe^{\omega X}) = g = g_1 - \frac{1}{\alpha_w \omega^2}fe^{\omega X}$ we have

$$\|(1 - \alpha_w \partial_X^2)^{-1}(fe^{\omega r})\|_{1,q} \leq \|g_1\|_{1,q} + C\omega^{-2}\|fe^{\omega r}\|_{1,q} \leq C\omega^{-1}\|f\|_{2,q}.$$ 

This establishes the estimate for $\omega^0 = -c_w^2(1 - \alpha_w \partial_X^2)^{-1}$. To establish it for $\omega^t$ observe that the estimates in Part (ii) give $\|(1 - \alpha_w \partial_X^2)\omega^t f\|_{r,q} \leq C\|f\|_{r,q}$. Thus we can reduce the $\omega^t$ estimate to the $\omega^0$ case in a simple way. □

7.12. Estimates for $B^t$. Finally we have several basic estimates for $B^t$. First we have some straightforward upper bounds.

Lemma 30. For all $r \geq 0$ there exists $C_r > 0$ such that for all $q, q' \in [0, q_2]$ and $\epsilon \in [0, \epsilon_1]$ we have the following estimates. If $q \geq q'$ then

$$\|B^t(\theta, \hat{\theta})\|_{r,q} \leq C_r\|\theta\|_{r,q'} \cosh(|q - q'|\cdot)J_2^r\hat{\theta}\|_{W^{r,\infty}}$$

for all $r \geq 0$. If $q \leq q'$ then

$$\|B^t(\theta, \hat{\theta})\|_{r,q} \leq C_r\|\theta\|_{r,q'} \sech(|q - q'|\cdot)J_2^r\hat{\theta}\|_{W^{r,\infty}}$$

for all $r \geq 0$. Lastly, if $0 \leq q' \leq q$ and $r \geq 1$ then

$$\|B^t(\theta, \hat{\theta})\|_{r,q} \leq C\|\theta\|_{r,q'} \|\hat{\theta}\|_{r,q - q'}.$$ 

Proof. First use the bound on $J_f^r$ in (7.22) from Corollary 23 to get $\|B^t(\theta, \hat{\theta})\|_{r,q} \leq \|J_2^r\theta \cdot J_2^r\hat{\theta}\|_{r,q}$. Using the various product estimates in Lemma 19 followed by the bound on $J_f^r$ in (7.22) from Corollary 23 gives the estimates. □

The next result deals with approximation of $B^t$ by $B^0$. 
Lemma 31. There exists $\epsilon_5, q_5 > 0$ such that for all $r \geq 0$ there exists $C_r > 0$ such that for $q \in [0, q_5]$ and $\epsilon \in (0, \epsilon_5]$ we have the following inequality

\[
\|B'(\theta, \dot{\theta}) - B^0(\theta, \dot{\theta})\|_{r,q} \leq C_r \epsilon \|\theta\|_{r+1,q'} \|\dot{\theta}\|_{r+1,q'}. \tag{7.36}
\]

Here $q + q' = q \in [0, q_4]$ and both are positive.

Proof. Let $\epsilon_5 := \min(1, \epsilon_1)$ and $q_5 := \min(q_2, \tau_2)$. The triangle inequality gives

\[
\|B'(\theta, \dot{\theta}) - B^0(\theta, \dot{\theta})\|_{r,q} = \left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} 
\]

\[
\leq \left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} + \left\| J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} + \left\| J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q}. \tag{7.37}
\]

For the first term, we use the bound on $J^c_1$ in (7.22) from Corollary 23 to get

\[
\left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} \leq C \left\| J^0_2 \theta, J^0_2 \dot{\theta} \right\|_{r,q}.
\]

Then we use the product inequality (7.14)

\[
\left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} \leq C \|\cosh(q') \| W_{r,\infty} \left\| J^0_2 \theta, J^0_2 \dot{\theta} \right\|_{r,q'}
\]

where we have $q' + q'' = q$ and both are positive. The Sobolev embedding theorem applied to the first term on the right hand side gives:

\[
\left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} \leq C \left\| J^0_2 \theta \right\|_{r+1,q'} \left\| J^0_2 \dot{\theta} \right\|_{r,q'}.
\]

Using the boundedness of $J^0_2$ we get

\[
\left\| J^c_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} \leq C \left\| \theta \right\|_{r+1,q'} \left\| J^0_2 \dot{\theta} \right\|_{r,q'}.
\]

On the second term we use the estimate (7.29) from Lemma 27 to arrive at:

\[
\left\| J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) - J^0_1 \left( J^0_2 \theta, J^0_2 \dot{\theta} \right) \right\|_{r,q} \leq C \epsilon \left\| \theta \right\|_{r+1,q'} \left\| \dot{\theta} \right\|_{r+1,q'}.
\]

So the first term in (7.37) is handled.

The rest of the terms in (7.37) are estimated in the same way, and we leave out the details. \qed

8. The proof of Proposition 15

We are now in position to estimate $N^\epsilon$ and prove Proposition 15. Put

\[
q_* := \min(q_0, q_1, q_2, q_3, q_4, q_5) \quad \text{and} \quad \epsilon_* := \min(\epsilon_0, \epsilon_1, \epsilon_2, \epsilon_3, \epsilon_4, \epsilon_5).
\]

In this section we restrict

\[
\epsilon \in (0, \epsilon_*) \quad \text{and} \quad q \in \left[ q_*/2, q_* \right].
\]
We have the lower bound on $q$ in place so that the constant $C_q$ in the estimates for $T_\epsilon$ and $P_\epsilon$ in Lemma 24 is bounded above. In this way, any constant $C > 0$ which appears below is independent of $\epsilon$, $q$, $\eta$ (which is $E_q^1 \times O_q^1$) and $a$ (which is in $[-a_0, a_0]$). Note that it is a consequence of Lemma 5 that if $\eta_1$ is even and $\eta_2$ is odd that $N_1^\epsilon$ and $N_2^\epsilon$ are even and odd, respectively.

8.1. The mapping estimates. In this subsection we prove the estimate (6.1). The definitions of $N_1^\epsilon$, $N_2^\epsilon$ and $N_3^\epsilon$ give us:

$$
\|N_1^\epsilon(\eta, a)\|_{1,q} \leq \|A^{-1}j_1\|_{1,q} + \|A^{-1}j_2\|_{1,q} + \|A^{-1}j_3\|_{1,q} + \|A^{-1}j_4\|_{1,q} + \|A^{-1}j_5\|_{1,q},
$$

$$
\|N_2^\epsilon(\eta, a)\|_{1,q} \leq \|\epsilon^2 P_1 l_1\|_{1,q} + \|\epsilon^2 P_2 l_2\|_{1,q} + \|\epsilon^2 P_3 l_3\|_{1,q} + \|\epsilon^2 P_4 l_4\|_{1,q} + \|\epsilon^2 P_5 l_5\|_{1,q},
$$

and

$$
|N_3^\epsilon(\eta, a)| \leq |\epsilon l_1| + |\epsilon l_2| + |\epsilon l_3| + |\epsilon l_4| + |\epsilon l_5|.
$$

Using the uniform bound (7.17) on $A^{-1}$ from Lemma 20 we have

$$
\|N_1^\epsilon(\eta, a)\|_{1,q} \leq C \left(\|j_1\|_{1,q} + \|j_2\|_{1,q} + \|j_3\|_{1,q} + \|j_4\|_{1,q} + \|j_5\|_{1,q}\right).
$$

In Lemma 24 the estimate (7.27) gives $\|P_\epsilon f\|_{1,q} \leq C \epsilon^{-1}\|f\|_{1,q}$. Thus

$$
\|N_2^\epsilon(\eta, a)\|_{1,q} \leq C\epsilon \left(\|l_1\|_{1,q} + \|l_2\|_{1,q} + \|l_3\|_{1,q} + \|l_4\|_{1,q} + \|l_5\|_{1,q}\right).
$$

And the Riemann-Lebesgue estimate for $\epsilon$, (7.18), following Lemma 21 gives (for $r = 1$)

$$
|N_3^\epsilon(\eta, a)| \leq C\epsilon \left(\|l_1\|_{1,q} + \|l_2\|_{1,q} + \|l_3\|_{1,q} + \|l_4\|_{1,q} + \|l_5\|_{1,q}\right).
$$

Thus we will have (6.1) if we can show that each of the ten terms

$$
\|j_1\|_{1,q}, \|j_2\|_{1,q}, \|j_3\|_{1,q}, \|j_4\|_{1,q}, \|j_5\|_{1,q}, \|l_1\|_{1,q}, \|l_2\|_{1,q}, \|l_3\|_{1,q}, \|l_4\|_{1,q}, \|l_5\|_{1,q}
$$

is bounded by $C|RHS_{\text{map}}|$, where

$$
|RHS_{\text{map}}| := \epsilon + \epsilon\|\eta\|_{1,q} + \epsilon|a| + \|\eta\|_{1,q}^2 + a^2.
$$

8.1.1. Mapping estimates for $j_1$ and $l_1$. The choice of $\sigma$ was made so that $\sigma + \varpi^0 b_1^0(\sigma, \sigma) = 0$. See (3.4). Which means that we have

$$
\varpi^0 b_1^0(\sigma, \sigma) = \varpi^0 b_1^0(\sigma, \sigma) + \varpi^0 \left(b_0^0(\sigma, \sigma) - b_1^0(\sigma, \sigma)\right).
$$

Call the terms on the right hand side $I$ and $II$ respectively.

To estimate $I$, we first use the estimate (7.31) for $\varpi^0 - \varpi^0$ to get $\|I\|_{1,q} \leq C\epsilon^2 \|b_1^0(\sigma, \sigma)\|_{1,q}$. Then we use the estimate for $B^0$ from (7.35) and get $\|I\|_{1,q} \leq C\epsilon^2 \|\sigma\|_{1,q/2}^2$. Then the uniform bounds (7.1) for $\sigma$ give $\|I\|_{1,q} \leq C\epsilon^2$.

For $II$ we use the smoothing property of $\varpi^0$ and the associated estimate (7.30) to get $\|II\|_{1,q} \leq C\epsilon \|b_1^0(\sigma, \sigma) - b_1^0(\sigma, \sigma)\|_{0,q}$. Then we use the approximation estimates for $B^0$ by $B^0$ in (7.36) to get $\|II\|_{1,q} \leq C\epsilon \|\sigma\|_{1,q/2}^2$. Then the uniform bounds (7.1) for $\sigma$ give $\|II\|_{1,q} \leq C\epsilon$. Thus we have

$$
\|j_1\|_{1,q} \leq C\epsilon \leq C|RHS_{\text{map}}|.
$$

To estimate $l_1 = \lambda_+^\epsilon b_2^\epsilon(\sigma, \sigma)$ is very easy using the bounds for $\lambda_+^\epsilon$ in (7.22), the bounds on $B^\epsilon$ in (7.35) and the bounds on $\sigma$ in (7.1). We get $\|l_1\|_{1,q} \leq C$. And so

$$
\|l_1\|_{1,q} \leq C\epsilon \leq C|RHS_{\text{map}}|.
$$
8.1.2. **Mapping estimates for** $j_2$ **and** $l_2$. By adding zero we see

$$j_2 = -2(\omega - \omega^0)b_1^0(\sigma, \eta) - 2\omega^0 \left(b_1(\sigma, \eta) - b_1^0(\sigma, \eta)\right).$$

Call these two terms $I$ and $II$ respectively.

To estimate $I$, we first use the estimate \(7.31\) for $\omega - \omega^0$ to get $\|I\|_{1,q} \leq C\epsilon^2\|b_1^0(\sigma, \eta)\|_{1,q}$. Then we use the estimate for $B^e$ from \(7.35\) and get $\|I\|_{1,q} \leq C\epsilon^2\|\sigma\|_{1,q}\|\eta\|_{1,0}$. Then the uniform bounds \(7.1\) for $\sigma$ give $\|I\|_{1,q} \leq C\epsilon\|\eta\|_{1,0}$. Thus we have

\[
8.1 \quad \|j_2\|_{1,q} \leq C\epsilon\|\eta\|_{1,0} \leq C|\text{RHS}_{\text{map}}|.
\]

To estimate $l_2 = \lambda_1 b_2^0(\sigma, \eta)$, as with $l_1$, is very straightforward using the bounds for $\lambda_1$ in \(7.22\), the bounds on $B^e$ in \(7.35\) and the bounds on $\sigma$ in \(7.1\). We get $\|l_2\|_{1,q} \leq C\|\eta\|_{1,0}$. And so

\[
8.2 \quad \epsilon\|l_2\|_{1,q} \leq C\epsilon\|\eta\|_{1,0} \leq C|\text{RHS}_{\text{map}}|.
\]

8.1.3. **Mapping estimates for** $j_3$ **and** $l_{31}$. Recalling the definition of $j_3$, we have

$$j_3 = -2a\omega^e J_1^e (J_2^0 \sigma J_3^0 \nu_e) \cdot i - 2a\omega^e J_1^e ((J_2^0 - J_2^e) \sigma J_3^0 \nu_e) \cdot i - 2a\omega^e B^e(\sigma, \varphi_e^a - \varphi_e^0) \cdot i$$

$$= j_{30} + j_{31}$$

with $j_{30} = -2a\omega^e J_1^e (J_2^0 \sigma J_3^0 \nu_e) \cdot i$ and $j_{31}$ is the rest.

First we will estimate $B^e(\sigma, \varphi_e^a - \varphi_e^0)$. Using the “decay borrowing estimate” \(7.34\) for $B^e$ we have

$$\|B^e(\sigma, \varphi_e^a - \varphi_e^0)\|_{r,q} \leq C_r\|\sigma\|_{q_0}\|\text{sech}(\|q_0 - q\|)J_2^e(\varphi_e^a - \varphi_e^0)\|_{W^{r,\infty}}.$$

Using the definition of the $W^{r,\infty}$ norm we get:

$$\|\text{sech}(\|q_0 - q\|)J_2^e(\varphi_e^a - \varphi_e^0)\|_{W^{r,\infty}} \leq C_r\|X\|_{q_0}\|\text{sup}_{X\in\mathbb{R}} \text{sech}(\|q_0 - q\|X)\sum_{n=0}^{r}(\partial^n_X J_2^e(\varphi_e^a - \varphi_e^0))\|.$$

We estimated $\partial^n_X J_2^e(\varphi_e^a - \varphi_e^0)$ above in \(7.33\). We use that estimate here to get

$$\|\text{sech}(\|q_0 - q\|)J_2^e(\varphi_e^a - \varphi_e^0)\|_{W^{r,\infty}} \leq C_r\epsilon^{-r}\|\text{sup}_{X\in\mathbb{R}} \text{sech}(\|q_0 - q\|X)(1 + |X|)|a|.$$

Our restrictions on $q$ imply $|q_0 - q|$ is strictly bounded away from zero in a way independent of $q$ or $\epsilon$. Thus $\sup_{X\in\mathbb{R}} \text{sech}(\|q_0 - q\|X)(1 + |X|)|a| \leq C$. And so we see that

$$\|\text{sech}(\|q_0 - q\|)J_2^e(\varphi_e^a - \varphi_e^0)\|_{W^{r,\infty}} \leq C_r\epsilon^{-r}|a|$$

which in turn gives

\[
8.3 \quad \|B^e(\sigma, \varphi_e^a - \varphi_e^0)\|_{r,q} \leq C_r\epsilon^{-r}|a|.
\]

This estimate is one of the keys for estimating $j_{31}$ and, as it happens, $l_{31}$. 
Estimation of $j_{31}$ goes as follows. First we use the smoothing estimate (7.30) for $\varpi^\epsilon$ from Lemma 28,

$$
\|j_{31}\|_{1,q} \leq C|a| \|\varpi^\epsilon J_1^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e)\|_{1,q} + C|a| \|\varpi^\epsilon B^\epsilon (\sigma, \varphi_e^\epsilon - \varphi_0^\epsilon)\|_{1,q} \\
\leq C|a| \|J_1^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e)\|_{0,q} + C|a| \|B^\epsilon (\sigma, \varphi_e^\epsilon - \varphi_0^\epsilon)\|_{0,q}.
$$

Then we use (8.3), with $r = 0$, on the second term to get

$$
\|j_{31}\|_{1,q} \leq C|a| \|J_1^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e)\|_{0,q} + C a^2.
$$

As for the first term, first we use the boundedness of $J_1^\epsilon$ from (7.22) followed by the product estimate (7.14):

$$
j_{31} \|_{1,q} \leq C|a| \|\varpi^\epsilon (J_2^\epsilon - J_0^0)\sigma \|_{0,q} \|J_2^\epsilon \nu_e\|_{W^{0,\infty}} + C a^2.
$$

Using the estimate for $\nu_e = \varphi_0^\epsilon$ in (7.2) gives

$$
j_{31} \|_{1,q} \leq C|a| \|(J_2^\epsilon - J_0^0)\sigma\|_{0,q} + C a^2.
$$

Then we use the estimate (7.29) for $J_2^\epsilon - J_0^0$ from Lemma 27 and the bounds on $\sigma$ in (7.1):

$$
j_{31} \|_{1,q} \leq C|a| + C a^2 \leq C|\text{R.H.S. map}|.
$$

Next we estimate $j_{30}$. Estimates like the ones we just used give

$$
j_{30} \|_{1,q} \leq C|a| \|\varpi^\epsilon J_1^\epsilon (J_0^0 \sigma J_2^\epsilon \nu_e)\|_{1,q} \leq C|a| \|J_1^\epsilon (J_0^0 \sigma J_2^\epsilon \nu_e)\|_{0,q} \leq C|a|.
$$

This is not less than $C|\text{R.H.S. map}|$. It turns out this estimate is not good enough for our purposes; basically, with this estimate $j_{30}$ looks like an $O(1)$ or a perturbation in our equation and will ruin our contraction mapping argument. But we can improve this using the estimate (7.32) from Lemma 28.

To wit $j_{30} \|_{1,q} = 2|a| \|\varpi^\epsilon J_1^\epsilon (J_0^0 \sigma J_2^\epsilon \nu_e)\|_{1,q}$. Using the boundedness (7.22) of $J_1^\epsilon$ from Corollary 28 we have $j_{30} \|_{1,q} \leq C|a| \|\varpi^\epsilon (J_0^0 \sigma J_2^\epsilon \nu_e)\|_{1,q}$. Then we apply $J_2^\epsilon$ to $\nu_e$ (as in (7.5)) and $J_2^\epsilon$ to $\sigma$ to get $j_{30} \|_{1,q} \leq C|a| \|\varpi^\epsilon (\sigma \epsilon K_\epsilon)\|_{1,q}$. Then we use the estimate (7.32) of Lemma 28 with $\omega = K_\epsilon$ to see $j_{30} \|_{1,q} \leq C|a| |K_\epsilon|^{-1} \|\sigma\|_{2,q}$. And since $K_\epsilon = O(1/\epsilon)$ we have $j_{30} \|_{1,q} \leq C \epsilon |a|$. This is one whole power of $\epsilon$ better than the naive estimate (8.5). With (8.4) we have

$$
j_{30} \|_{1,q} \leq C \epsilon |a| + C a^2 \leq C|\text{R.H.S. map}|.
$$

To estimate $l_3$ is much the same, though recall that we do not need to estimate all of $l_3$, rather just the term $l_{31}$. As with $j_{30}$ above, we have:

$$
l_3 = -2a \lambda^\epsilon J_0^\epsilon (J_2^0 \sigma J_2^\epsilon \nu_e) \cdot j - 2a \lambda^\epsilon J_1^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e) \cdot j - 2a \lambda^\epsilon B^\epsilon (\sigma, \varphi_e^\epsilon - \varphi_0^\epsilon) \cdot j.
$$

Since $\lambda^\epsilon := -2a \lambda^\epsilon J_0^\epsilon (J_2^0 \sigma J_2^\epsilon \nu_e) \cdot j$ we see that

$$
l_{31} = -2a \lambda^\epsilon J_0^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e) \cdot j - 2a \lambda^\epsilon B^\epsilon (\sigma, \varphi_e^\epsilon - \varphi_0^\epsilon) \cdot j.
$$

Now that we have an explicit formula for $l_{31}$, we use the boundedness (7.22) of $\lambda^\epsilon$:

$$
l_{31} \|_{1,q} \leq C|a| \|J_0^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e)\|_{1,q} + C|a| \|B^\epsilon (\sigma, \varphi_e^\epsilon - \varphi_0^\epsilon)\|_{1,q}.
$$

Then we use (8.3), with $r = 1$, on the second term:

$$
j_{31} \|_{1,q} \leq C|a| \|J_1^\epsilon ((J_2^\epsilon - J_0^0)\sigma J_2^\epsilon \nu_e)\|_{1,q} + C \epsilon^{-1} a^2.
$$
For the first term, first we use the boundedness of $J_1^e$ from (7.22) followed by the product estimate (7.14):
\[ ||l_{31}||_{1,q} \leq C|a||(J_2^e - J_0^e)\sigma||J_2^e\nu_c||_{W^{1,\infty}} + C\epsilon^{-1}a^2.\]
Using the estimate for $\nu_c = \varphi_c^0$ in (7.2), with $r = 1$, gives
\[ ||l_{31}||_{1,q} \leq C\epsilon^{-1}|a||(J_2^e - J_0^e)\sigma||_{0,q} + C\epsilon^{-1}a^2.\]
Then we use the estimate (7.29) for $J_2^e - J_0^e$ from Lemma 27 and the bounds on $\sigma$ in (7.1)
\[ ||l_{31}||_{1,q} \leq C|a| + C\epsilon^{-1}a^2.\] Thus
(8.8) \[ \epsilon||l_{31}||_{1,q} \leq C\epsilon|a| + Ca^2 \leq C|RHS_{map}|. \]
and we can move on.

8.1.4. Mapping estimates for $l_4$ and $l_5$. Applying the estimate (7.33) for $B^e$ gives $\|B^e(\eta, \varphi_c^0)||_{r,q} \leq Cr\|\eta||_{r,q}\|J_2^e\varphi_c^0||_{W^{r,\infty}}.$ Then (7.2) gives
(8.9) \[ ||B^e(\eta, \varphi_c^0)||_{r,q} \leq Cr\epsilon^{-r}\|\eta||_{r,q}. \]
And so, using the same steps as in the previous subsection, we get:
\[ ||j_4||_{1,q} \leq C|a||\varphi_c^0||\|\eta||_{1,q} \leq C|a||\|\eta||_{1,q} \leq C|RHS_{map}|. \]
and
\[ \epsilon||l_4||_{1,q} \leq C\epsilon|a||\|\eta||_{1,q} \leq C|RHS_{map}|. \]

8.1.5. Mapping estimates for $l_5$. Using (7.35) we have $\|B^e(\eta, \eta)||_{r,q} \leq Cr\|\eta||_{r,q/2}^2.$ Thus
\[ ||j_5||_{1,q} \leq C\|\eta||_{1,q/2} \leq C|RHS_{map}| \quad \text{and} \quad \epsilon||l_5||_{1,q} \leq C\epsilon\|\eta||_{1,q/2} \leq C|RHS_{map}|. \]
With these estimates, the validation of the mapping estimate (6.1) is complete. We move on to the Lipschitz estimates.

8.2. The Lipschitz estimates. Now we prove the estimate (6.2). In this subsection $\dot{J}_n$ is the same as $j_n$ but evaluated at $\dot{\eta}$ and $\dot{a}$ instead of at $\eta$ and $a$. Likewise $\dot{l}_n$ is the same as $l_n$ but evaluated at $\dot{\eta}$ and $\dot{a}$ instead of at $\eta$ and $a$. Also we have $q_s/2 \leq q < q' \leq q_*$. We have by definition and the triangle inequality:
\[ \|N_1^e(\eta, a) - N_1^e(\dot{\eta}, \dot{a})\|_{1,q} \leq \|A^{-1}(j_2 - \dot{j}_2)\|_{1,q} + \|A^{-1}(j_3 - \dot{j}_3)\|_{1,q} + \|A^{-1}(j_4 - \dot{j}_4)\|_{1,q} + \|A^{-1}(j_5 - \dot{j}_5)\|_{1,q} \]
\[ \|N_2^e(\eta, a) - N_2^e(\dot{\eta}, \dot{a})\|_{1,q} \leq \|\epsilon^2 \mathcal{P}_c(l_2 - \dot{l}_2)\|_{1,q} + \|\epsilon^2 \mathcal{P}_c(l_31 - \dot{l}_31)\|_{1,q} + \|\epsilon^2 \mathcal{P}_c(l_4 - \dot{l}_4)\|_{1,q} + \|\epsilon^2 \mathcal{P}_c(l_5 - \dot{l}_5)\|_{1,q} \]
and
\[ \|N_3^e(\eta, a) - N_3^e(\dot{\eta}, \dot{a})\| \leq \bigg| \epsilon[l_2 - \dot{l}_2] \bigg| + \bigg| \epsilon[l_31 - \dot{l}_31] \bigg| + \bigg| \epsilon[l_4 - \dot{l}_4] \bigg| + \bigg| \epsilon[l_5 - \dot{l}_5] \bigg|. \]
8.2.1. Lipschitz estimates for $j_2$ and $l_2$. Note that $j_2$ and $l_2$ are linear in $\eta$ and do not depend at all on $a$. Thus we can use the estimates (8.1) and (8.2) to get:

\[ \| j_2 - \hat{j}_2 \|_{1,q} \leq C \| \eta - \hat{\eta} \|_{1,0} \leq C \| \text{RHS}_{\text{tip}} \| \quad \text{and} \quad \epsilon \| l_2 - \hat{l}_2 \|_{1,q} \leq C \epsilon \| \eta - \hat{\eta} \|_{1,0} \leq C \| \text{RHS}_{\text{tip}} \| . \]

8.2.2. Lipschitz estimates for $j_3$ and $l_3$. Explicit computations give

\[ j_3 - \hat{j}_3 = -2(a - \hat{a}) \varpi^\epsilon J_1^0 \left( J_2^0 \sigma, J_2^0 \nu_\epsilon \right) \cdot i - 2(a - \hat{a}) \varpi^\epsilon \left( J_2^0 - J_2^0 \right) \sigma \cdot J_2^0 \nu_\epsilon \cdot i \]

\[ - 2(a - \hat{a}) \varpi^\epsilon B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0) \cdot i + 2 \hat{a} \varpi^\epsilon B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0) \cdot i \]

and

\[ l_{31} - \hat{l}_{31} = -2(a - \hat{a}) \lambda^e_+ J_1^0 \left( (J_2^0 - J_2^0) \sigma, J_2^0 \nu_\epsilon \right) \cdot \hat{j} \]

\[ - 2(a - \hat{a}) \lambda^e_+ B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0) \cdot j + 2 \hat{a} \lambda^e_+ B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0) \cdot j. \]

We begin with an estimate of $B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0)$. This estimate parallels the one for $B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0)$ in (8.3). Using the “decay borrowing estimate” (7.34) for $B^e$ we have

\[ \| B^e(\sigma, \varphi_\epsilon^0 - \varphi_\epsilon^0) \|_{r,q} \leq C_r \| \sigma \|_{q_0} \| \text{sech}(|q_0 - q|)J_2^0(\varphi_\epsilon^0 - \varphi_\epsilon^0) \|_{W^{r,\infty}}. \]

Using the definition of the $W^{r,\infty}$ norm we get:

\[ \| \text{sech}(|q_0 - q|)J_2^0(\varphi_\epsilon^0 - \varphi_\epsilon^0) \|_{W^{r,\infty}} \leq C_r \sup_{X \in \mathbb{R}} \left| \text{sech}(|q_0 - q|X) \sum_{n=0}^r \partial_X^n J_2^0(\varphi_\epsilon^0 - \varphi_\epsilon^0) \right|. \]

We estimated $\partial_X^n J_2^0(\varphi_\epsilon^0 - \varphi_\epsilon^0)$ above in (7.33) in Lemma 18. We use that estimate here to get

\[ \| \text{sech}(|q_0 - q|)J_2^0(\varphi_\epsilon^0 - \varphi_\epsilon^0) \|_{W^{r,\infty}} \leq C_r \epsilon^{-r} \sup_{X \in \mathbb{R}} \left| \text{sech}(|q_0 - q|X)(1 + |X|) \right| |a - \hat{a}|. \]
We know that \( \sup_{X\in\mathbb{R}} |\text{sech}(|q_0 - q|X)(1 + |X|)| \leq C \) and so
\[
\| \text{sech}(|q_0 - q|\cdot)J''_2(\varphi^a_\epsilon - \varphi^b_\epsilon) \|_{W^{r,\infty}} \leq C_\epsilon e^{-r}|a - \hat{a}|
\]
which in turn gives
\[
(8.11) \quad \| B^r(\sigma, \varphi^a_\epsilon - \varphi^b_\epsilon) \|_{r,q} \leq C_\epsilon e^{-r}|a - \hat{a}|.
\]

The formulas for \( j_3 - \hat{j}_3 \) and \( l_31 - \hat{l}_31 \) differ only slightly from those for \( j_3 \) and \( l_31 \). Any differences there are can be handled with (8.11); we leave out the steps. The results are
\[
\| j_3 - \hat{j}_3 \|_{1,q} \leq C\epsilon|a - \hat{a}| + C (|a| + |\hat{a}|) |a - \hat{a}| \leq C|RHS_{\text{tip}}|
\]
and
\[
\epsilon \| l_31 - \hat{l}_31 \|_{1,q} \leq C\epsilon|a - \hat{a}| + C (|a| + |\hat{a}|) |a - \hat{a}| \leq C|RHS_{\text{tip}}|.
\]

8.2.3. Lipschitz estimates for \( j_4 \) and \( l_4 \). Much of this parallels the earlier treatment of \( j_3 \) and \( l_3 \), just swapping out \( \sigma \) for \( \eta \). There is one major wrinkle however: varying \( a \) results in a loss of decay rate \( q \) for \( \eta \). This is not terribly surprising given the estimate (7.3). Thus we must keep careful track of the decay rates. So fix \( q \in [q_*/2, q_*) \).

We look at \( B^r(\eta, \varphi^a_\epsilon - \varphi^b_\epsilon) \). We use the decay borrowing estimate (7.34) to get, if \( q' > q \),
\[
\| B^r(\eta, \varphi^a_\epsilon - \varphi^b_\epsilon) \|_{r,q} \leq C_\epsilon \| \eta \|_{r,q'} \| \text{sech}(|q - q'|\cdot)J''_2(\varphi^a_\epsilon - \varphi^b_\epsilon) \|_{W^{r,\infty}}.
\]
As with the estimates that led to (8.10), we can use (7.3) to get
\[
\| \text{sech}(|q - q'|\cdot)J''_2(\varphi^a_\epsilon - \varphi^b_\epsilon) \|_{W^{r,\infty}} \leq C_\epsilon e^{-r} \sup_{X\in\mathbb{R}} |\text{sech}(|q - q'|X)(1 + |X|)| |a - \hat{a}|.
\]
Now, however, we do not know that \( |q - q'| \) is bounded strictly from zero.

Elementary calculus can be used to show that
\[
\sup_{X\in\mathbb{R}} |(1 + |X|) \text{sech}(|q - q'|X)| \leq C|q - q'|^{-1}.
\]
Thus we have
\[
(8.12) \quad \| B^r(\eta, \varphi^a_\epsilon - \varphi^b_\epsilon) \|_{r,q} \leq C_\epsilon e^{-r} |q - q'|^{-1} \| \eta \|_{r,q'} |a - \hat{a}| \quad \text{when } q' > q.
\]

Now the triangle inequality and bilinearity of \( B^r \) give:
\[
\| B^r(\eta, a\varphi^a_\epsilon) - B^r(\hat{\eta}, a\varphi^b_\epsilon) \|_{r,q} \leq |a| \| B^r(\eta, \varphi^a_\epsilon - \varphi^b_\epsilon) \|_{r,q} + |a - \hat{a}| \| B^r(\eta - \hat{\eta}, a\varphi^a_\epsilon) \|_{r,q}
\]
So if we use (8.9) and (8.12) we get:
\[
\| B^r(\eta, a\varphi^a_\epsilon) - B^r(\hat{\eta}, a\varphi^b_\epsilon) \|_{r,q} \leq C_\epsilon e^{-r} |q - q'|^{-1} \| \eta \|_{r,q'} |a - \hat{a}| + C_\epsilon e^{-r} \| \eta - \hat{\eta} \|_{r,q} \quad \text{when } q' > q.
\]
This estimate, together with the sorts of steps we have used above, lead to:
\[
\| j_4 - \hat{j}_4 \|_{1,q} \leq C|q - q'|^{-1} (\| \eta \|_{1,q'} |a - \hat{a}| + \| \eta \|_{1,q} |a - \hat{a}| + |\hat{a}| \| \eta - \hat{\eta} \|_{1,q}) \leq C|RHS_{\text{tip}}|
\]
and
\[
\epsilon \| l_4 - \hat{l}_4 \|_{1,q/2} \leq C|q - q'|^{-1} (\| \eta \|_{1,q'} |a - \hat{a}| + \| \eta \|_{1,q} |a - \hat{a}| + |\hat{a}| \| \eta - \hat{\eta} \|_{1,q}) \leq C|RHS_{\text{tip}}|
\]
so long as \( q_*/2 \leq q < q_* \).
8.2.4. Lipschitz estimates for \( j_5 \) and \( l_5 \). Using (7.35) from Lemma 30 gives
\[
\| B^\epsilon(\eta, \eta) - B^\epsilon(\hat{\eta}, \hat{\eta}) \|_{r,q} \leq C(\| \eta \|_{r,q/2} + \| \hat{\eta} \|_{r,q/2}) \| \eta - \hat{\eta} \|_{r,q/2}.
\]
Thus
\[
\| j_5 - \hat{j}_5 \|_{r,1} \leq C(\| \eta \|_{1,q/2} + \| \hat{\eta} \|_{1,q/2}) \| \eta - \hat{\eta} \|_{1,q/2} \leq C|\text{RHS}_{\text{lip}}|.
\]

This completes the estimate that give rise to (6.2) and we move on to the bootstrap estimates.

8.3. The bootstrap estimates. In this section we prove the estimates (6.3) and (6.4). The triangle inequality gives:
\[
\| N_1(\eta, a) \|_{r+1,q} \leq \| A^{-1} j_1 \|_{r+1,q} + \| A^{-1} j_2 \|_{r+1,q} + \| A^{-1} j_3 \|_{r+1,q} + \| A^{-1} j_4 \|_{r+1,q} + \| A^{-1} j_5 \|_{r+1,q}
\]

\[
\| N_2(\eta, a) \|_{r+1,q} \leq \| \epsilon^2 P_1 l_1 \|_{r+1,q} + \| \epsilon^2 P_2 l_2 \|_{r+1,q} + \| \epsilon^2 P_3 l_3 \|_{r+1,q} + \| \epsilon^2 P_4 l_4 \|_{r+1,q} + \| \epsilon^2 P_5 l_5 \|_{r+1,q}
\]

and
\[
\| N_3(\eta, a) \| \leq \| \epsilon l_1 \| + \| \epsilon l_2 \| + \| \epsilon l_3 \| + \| \epsilon l_4 \| + \| \epsilon l_5 \|
\]

Using the bound (7.17) for \( A^{-1} \) we have
\[
\| N_1(\eta, a) \|_{r+1,q} \leq C_r \left( \| j_1 \|_{r+1,q} + \| j_2 \|_{r+1,q} + \| j_3 \|_{r+1,q} + \| j_4 \|_{r+1,q} + \| j_5 \|_{r+1,q} \right).
\]

As seen in Lemma 24, the operator \( P_\epsilon \) is smoothing by up to two derivatives. However each derivative of smoothing comes at a cost of an additional negative power of \( \epsilon \). Choosing to smooth by just one derivative we have:
\[
\| N_2(\eta, a) \|_{r+1,q} \leq C \left( \| l_1 \|_{r,q} + \| l_2 \|_{r,q} + \| l_3 \|_{r,q} + \| l_4 \|_{r,q} + \| l_5 \|_{r,q} \right).
\]

And the Riemann-Lebesgue estimate (7.18) in Lemma 21
\[
\| N_3^r(\eta, a) \| \leq C \epsilon^r \left( \| l_1 \|_{r,q} + \| l_2 \|_{r,q} + \| l_3 \|_{r,q} + \| l_4 \|_{r,q} + \| l_5 \|_{r,q} \right).
\]

Thus we will have (6.3) and (6.4) if we can show that each of the ten terms
\[
\| j_1 \|_{r+1,q}, \| j_2 \|_{r+1,q}, \| j_3 \|_{r+1,q}, \| j_4 \|_{r+1,q}, \| j_5 \|_{r+1,q}, \| l_1 \|_{r,q}, \| l_2 \|_{r,q}, \| l_3 \|_{r,q}, \| l_4 \|_{r,q}, \text{ and } \| l_5 \|_{r,q}
\]
is bounded by \( C_r|\text{RHS}_{\text{boot}}| \), where
\[
|\text{RHS}_{\text{boot}}| := \epsilon + \| \eta \|_{r,q} + \epsilon^{1-r} |a| + \epsilon^{-r} |a|^2 + \epsilon^{-r} |a| \| \eta \|_{r,q} + \| \eta \|_{r,q}^2.
\]

8.3.1. Bootstrap estimates \( j_1 \) and \( l_1 \). Since \( \sigma \) is a smooth function, the estimates on \( j_1 \) and \( l_1 \) can be improved from above more or less for free. Specifically we have, for any \( r \geq 0 \), we have
\[
\| j_1 \|_{r+1,q_0} + \| l_1 \|_{r,q_0} \leq C_r \epsilon \leq C_r|\text{RHS}_{\text{boot}}|.
8.3.2. **Bootstrap estimates for \( j_2 \) and \( l_2 \).** Recall that \( j_2 = -2\varpi^b(\sigma, \eta) + 2\varpi^b(\sigma, \eta) \). From the estimate (7.30) in Lemma 28, we see that the operators \( \varpi^b \) and \( \varpi^0 \) smooth by up to two derivatives at no cost in \( \epsilon \). Thus we conclude, with the help of (7.35),

\[
\| j_1 \|_{r+1,q} \leq C_r \| b'_1(\sigma, \eta) \|_{r,q} + C_r \| b'_0(\sigma, \eta) \|_{r,q} \leq C_r \| \eta \|_{r,q} \leq C_r |RHS_{\text{boot}}|.
\]

Since \( l_2 = 2b'_2(\sigma, \eta) \), we use (7.35) and see that

\[
\| l_2 \|_{r,q} \leq C_r \| \eta \|_{r,q} \leq C_r |RHS_{\text{boot}}|.
\]

8.3.3. **Bootstrap estimates for \( j_3 \) and \( l_3 \).** Since \( \varpi^b \) smooths by up to two derivatives we have, using (7.30), \( \| j_3 \|_{r+1,q} \leq C_r \| b'_1(\varpi^a, \varphi^a) \|_{r,q} \). Then using the product inequality for \( B^e \) in (7.33) followed by the estimate for \( J^e \varphi^a \) in (7.2) gives

\[
\| j_3 \|_{r+1,q} \leq C_r \| \varpi^a \|_{r,q} \| J^e \varphi^a \|_{r+1,\infty} \leq C_r \epsilon^{1-r} |a|.
\]

We saw above that \( l_3 = -2aJ_1^e ((J^e - J^0) \sigma J^e \nu) \cdot j - 2aB^e(\sigma, \varphi^a - \varphi^0) \cdot j \). The estimate of this in \( H^r_q \) is not much different than our earlier estimate in \( H^r_q \). Specifically, using (7.22) and (7.14):

\[
\| j_1^e ((J^e - J^0) \sigma J^e \nu) \cdot j \|_{r,q} \leq C_r \| (J^e - J^0) \sigma \|_r \| J^e \nu \|_{r+1,\infty}.
\]

Using the approximation inequality (7.29) on the first term and then the bounds on \( \varphi^a \) in (7.2) for the second gives

\[
\| j_1^e ((J^e - J^0) \sigma J^e \nu) \cdot j \|_{r,q} \leq C_r \epsilon^{1-r}.
\]

Then we recall (8.3) gives \( \| B^e(\sigma, \varphi^a - \varphi^0) \|_{r,b} \leq C_r \epsilon^{-r} |a| \) and so all together we find that

\[
\| l_3 \|_{r,q} \leq C_r \epsilon^{1-r} |a| + C_r \epsilon^{-r} a^2 \leq C |RHS_{\text{boot}}|.
\]

8.3.4. **Bootstrap estimates \( j_4 \) and \( l_4 \).** Since \( \varpi^b \) smooths by two derivatives we have, after using (7.30), \( \| j_4 \|_{r+1,q} \leq C_r \| b'_1(\sigma, \varphi^a) \|_{r,q} \). Then using the product inequality (7.33) and the \( \varphi \) bound (7.2) gives

\[
\| j_4 \|_{r+1,q} \leq C_r \| \varphi^a \|_{r,q} \| J^e \varphi^a \|_{r+1,\infty} \leq C_r \epsilon^{-r} |a| \| \eta \|_{r,q} \leq C_r |RHS_{\text{boot}}|.
\]

The term \( l_4 \) has no smoothing operator attached, but is otherwise estimated in the same way. We have

\[
\| l_4 \|_{r,q} \leq C_r \| \varphi^a \|_{r,q} \| J^e \varphi^a \|_{r+1,\infty} \leq C_r \epsilon^{-r} |a| \| \eta \|_{r,q} \leq C_r |RHS_{\text{boot},1}|.
\]

8.3.5. **Bootstrap estimates for \( j_5 \) and \( l_5 \).** Since \( \varpi^b \) smooths by up to two derivatives we have, after using (7.30) and (7.35),

\[
\| j_5 \|_{r+1,q} \leq C_r \| \eta \|_{r,q}^2 \leq C_r |RHS_{\text{boot}}|.
\]

The term \( l_5 \) has no smoothing operator attached, but is otherwise estimated in the same way. We have

\[
\| l_5 \|_{r,q} \leq C_r \| \eta \|_{r,q}^2 \leq C_r |RHS_{\text{boot}}|.
\]

That completes our proof of (6.3), (6.4) and Proposition 15.
9. **Function analysis**

In this section we prove Lemmas 2, 11, 12, 13, 25 and 29. Each of these lemmas gives quantitative estimates for some specific meromorphic function. We use little more than foundational methods from real and complex analysis here though their implementation is sometimes complicated.

### 9.1. Multiplier properties in C.

This subsection contains the proofs of Lemmas 2, 25 and 29.

**Proof.** (of Lemma 2) Parts (i), (iii) and (iv) are easily inferred from properties of cosine.

For Part (ii) note that so long as \( \Re((1 - w)^2 + 4w \cos^2(z)) > 0 \) we can use the principal square root to extend \( \tilde{g}(k) \) analytically into the complex plane. Complex trigonometry identities show that

\[
\Re((1 - w)^2 + 4w \cos^2(k + i\tau)) = 1 + w^2 + 2w\cos(2k)\cosh(2\tau) \\
\geq 1 + w^2 - 2w\cosh(2\tau) =: f(\tau).
\]

Note that \( f(0) = (1 - w)^2 \). Since \( w > 1 \), this is strictly positive. Thus we can find \( \tau_0 > 0 \) such that \( f(\tau) > (1 - w)^2/2 \) when \( |\tau| \leq \tau_0 \). In turn this implies that \( \tilde{g}(z) \) (and thus \( \tilde{\lambda}_\pm(z) \)) is analytic when \( |\Im(z)| \leq \tau_0 \). Since the functions are periodic in the real direction and the strip \( \Sigma_{\tau_0} \) is bounded in the imaginary direction, the extreme value theorem implies that the functions (and all their derivatives) are uniformly bounded on it. Thus we have (ii).

For Part (v), we compute

\[
|\tilde{\lambda}'_\pm(k)| = \frac{4w \sin(k) \cos(k)}{\sqrt{(1 + w)^2 - 4w \sin^2(k)}} = 2c_w^2 |\sin(k)| \frac{\cos(k)}{\sqrt{1 - \frac{4w}{(1+w)^2} \sin^2(k)}}.
\]

It is clear that

\[
\sup_{s \in [0,1]} \frac{1 - s}{1 - rs} \leq 1
\]

when \( 0 \leq r \leq 1 \). The fact that \( w > 1 \) implies that \( 0 < 4w/(1 + w)^2 < 1 \). Thus

\[
\sup_{k \in \mathbb{R}} \frac{\cos(k)}{\sqrt{1 - \frac{4w}{(1+w)^2} \sin^2(k)}} = \sup_{k \in \mathbb{R}} \sqrt{1 - \frac{1 - \sin^2(k)}{1 - \frac{4w}{(1+w)^2} \sin^2(k)}} \leq 1.
\]

Since \( |\sin(k)| \leq |k| \) for all \( k \), this gives \( |\tilde{\lambda}'_\pm(k)| \leq 2c_w^2 |k| \), the second inequality in Part (v).

The first inequality is simpler and omitted. Since \( c_w^2 = 2w/(1 + w) \) and \( w > 1 \) we have \( c_w^2 > 1 \).

For Part (vi), by (iv) we have \( \tilde{\lambda}_+(k) \in [2w, 2 + 2w] \) for all \( k \). We have \( c^2k^2 < 2w \) when \( |k| < \sqrt{2w}/c =: k_1 \) and \( c^2k^2 > 2 + 2w \) when \( |k| > \sqrt{2 + 2w}/c =: k_2 \). Since our functions are continuous, the intermediate value theorem implies that there is at least one value of \( k \) such that \( c^2k^2 = \tilde{\lambda}_+(k) \) in \([k_1, k_2]\). Likewise, there can be no solutions of outside \([k_1, k_2]\).
Now put \( c_- = 5/4\sqrt{2} \in (0, 1) \) and assume \( c > c_- \). If \( k \geq k_1 \), and because \( w > 1 \), we have
\[
2c^2 k \geq 2c^2k_1 = 2c\sqrt{2w} \geq 2\sqrt{2}c_- = \frac{5}{2}.
\]
This implies that
\[
(9.1) \quad \left| \frac{d}{dk} \left( c^2k^2 - \tilde{\lambda}_+(k) \right) \right| = \left| 2c^2 k - \tilde{\lambda}_+'(k) \right| \geq \frac{5}{2} - 2 = l_0 > 0
\]
when \( k \geq k_1 \). This implies that there can be at most one solution of \( c^2k^2 - \tilde{\lambda}(k) = 0 \) for \( k \geq k_1 \) and also gives the estimate for \( |2c^2k - \tilde{\lambda}_+'(k_c)| \). The smoothness of the map \( c \mapsto k_c \) follows in a routine way from this derivative estimate and the implicit function theorem. Thus we have all of Part (vi).

Proof. (of Lemma 25) Take \( c_- \) as in the proof of Lemma 2 and let \( c_+ = \sqrt{c_w^2 + 1} \) when \( c > c_- \). Note that Part (vi) of that lemma tells us that \( \xi_c(k_c) = 0 \) and \( |\xi'_c(k_c)| \geq l_0 \). Henceforth assume \( c \in (c_-, c_+) \). Clearly \( c_w \in (c_-, c_+) \). Parts (i) and (ii) follow immediately from Lemma 2. And so all that remains is to prove the estimate \( (7.28) \) in Part (iii).

Estimates when \( |z| \) is large: First, note that since \( \tilde{\lambda}_+(z) \) is bounded in \( \Sigma_{\tau_0} \) there exists \( k_{\text{big}} > 0 \) such that \( |\Re(z)| \geq k_{\text{big}} \) and \( \Im(z) \leq \tau_0 \) implies
\[
|\tilde{\xi}_c(z)| \geq \frac{1}{2}c_w^2|z|^2
\]
for any \( c \in (c_-, c_+) \). So clearly, for \( j = 0, 1, 2 \), we have
\[
(9.2) \quad \inf_{k \geq k_{\text{big}}} (1 + k^2)^{-j/2}|\tilde{\xi}_c(k + i\tau)| \geq C_1 > 0
\]
where \( C_1 \) does not depend on \( c \). Thus we only need to concern ourselves with \( |\Re(z)| \leq k_{\text{big}} \). Our next step is near \( k_c \).

Estimates when \( z \sim k_c \): Since \( \tilde{\xi}''_c(z) = -2c^2 + \tilde{\lambda}_+(z) \) there exists \( C_2 < 0 \) such that \( |\tilde{\xi}''_c(z)| \leq C_2 \) for all \( z \in \Sigma_{\tau_0} \) and \( c \in (c_-, c_+) \). This implies \( |\tilde{\xi}'_c(z) - \tilde{\xi}'_c(z')| \leq C_2|z-z'| \) for all \( z, z' \in \Sigma_{\tau_0} \). Thus if \( |z - k_c| \leq \delta_1 := l_0/2C_2 \) this implies \( |\tilde{\xi}'_c(z) - \tilde{\xi}'_c(k_c)| \leq l_0/2 \). Note that \( \delta_1 \) does not depend on \( c \). The reverse triangle inequality gives
\[
|\tilde{\xi}'_c(z)| = \left| |\tilde{\xi}'_c(k_c)| - |\tilde{\xi}'_c(z) - \tilde{\xi}'_c(k_c)| \right| \geq \frac{l_0}{2}
\]
provided \( |z - k_c| \leq \delta_1 \). The FTOC then implies
\[
|\tilde{\xi}_c(z)| \geq \frac{l_0}{2}|z - k_c|
\]
for all \( |z - k_c| \leq \delta_1 \) and \( c \in (c_-, c_+) \).

Thus if \( z = k + i\tau \) and \( |z - k_c| \leq \delta_1 \) then
\[
(9.3) \quad |\tilde{\xi}_c(z)| \geq \frac{l_0}{2}|z - k_c| \geq \frac{l_0}{2}|	au|
\]
for any \( c \in (c_-, c_+) \).
Estimates for $z$ everywhere else: Now we know that $k_c$ depends smoothly on $c$. So select $\delta > 0$ such that $|c - c_w| \leq \delta$ implies $|k_c - k_{cw}| \leq \frac{1}{100} \delta_1$. Let $K := [0, k_{cw} - \delta_1/2] \cup [k_{cw} + \delta_1/2, k_{big}]$. Let

$$m_* := \inf_{|k| \in K} \inf_{k \in \mathbb{R}, |c - c_w| \leq \delta} |\tilde{\xi}_c(k)|$$

This number is strictly positive, since the only real zeros for $\tilde{\xi}_c(k)$, by the definition of $\delta$, lie outside of $K$, which is compact.

In the set $\{|\Re(z)| \leq k_{big}, |\Im(z)| \leq \tau_0\}$, which is compact, $\xi_c(z)$ is Lipschitz with a constant (say $C_3 > 0$) that, so long as $c$ lies in a compact set, is bounded independent of $c$. Thus, if $|k| \in K$ and $|\tau| \leq m_*/2C_3$ we have

$$|\tilde{\xi}_c(k + i\tau) - \tilde{\xi}_c(k)| \leq C_3|\tau| \leq m_*/2.$$

The reverse triangle inequality then gives

$$|\tilde{\xi}_c(k + i\tau)| \geq |\tilde{\xi}_c(k)| - C_3|\tau| \geq m_*/2.$$  \hfill (9.4)

Overall estimates: So put $\tau_3 := \min(\delta_1/2, \tau_0, m_/2C_3)$. If $z = k + i\tau$ with $|\tau| \leq \tau_3$ then notice that we have either (a) $|k| \in K$, (b) $|k - k_c| \leq \delta_1$ or (c) $|k| \geq k_{big}$. Thus we can use either (9.2), (9.3) or (9.4) to see that

$$(1 + k^2)^{-j/2}|\tilde{\xi}_c(k + i\tau)| \geq C|\tau|$$

where $C > 0$. This completes the proof.

Proof. (of Lemma 29) We have the series expansion $\tilde{\lambda}_-(z) = c_w^2z^2 - \alpha_wz^4 + \cdots$. So if we put

$$\tilde{\zeta}(z) := \frac{\tilde{\lambda}_-(z)}{z^2}$$

we see the singularity at $z = 0$ is removable. Since $\tilde{\lambda}_-(z)$ is analytic and uniformly bounded in the strip $\Sigma_{\tau_0}$, we have the same for $\tilde{\zeta}(z)$. With this, we rewrite $\tilde{\omega}$ as:

$$\tilde{\omega}(Z) = -\frac{e^2\tilde{\lambda}_-(\epsilon Z)}{(c_w^2 + \epsilon^2)^2Z^2 - \tilde{\lambda}(\epsilon Z)} = -\frac{e^2\tilde{\zeta}(\epsilon Z)}{c_w^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z)}.$$ 

Obviously $\tilde{\zeta}(z) = c_w^2 - \alpha_wz^2 + \cdots$. And so Taylor’s theorem (with the uniform bound) then implies there exists $C_1 > 0$ such that for all $z$ in the strip $\Sigma_{\tau_0}$ we have:

$$|\tilde{\zeta}(z)| \leq C_1, \quad |\tilde{\zeta}(z) - c_w^2| \leq C_1|z|^2, |\tilde{\zeta}(z) - c_w^2 + \alpha_wz^2| \leq C_1|z|^4.$$  \hfill (9.5)

Likewise, the uniform bound on $\tilde{\zeta}'(z)$ implies

$$|\tilde{\zeta}'(z)| \leq C_1|z|$$

for all $z, z'$ in the strip $\Sigma_{\tau_0}$.

Estimates near $Z = 0$: The reverse triangle inequality gives:

$$|c_w^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z)| = |\epsilon^2 + \epsilon^2\alpha_wZ^2 + (c_w^2 - \epsilon^2\alpha_wZ^2 - \tilde{\zeta}(\epsilon Z))|$$

$$\geq |\epsilon^2(1 + \alpha_wZ^2) - |c_w^2 - \epsilon^2\alpha_wZ^2 - \tilde{\zeta}(\epsilon Z)|$$
If \( Z = K + i q \), then we have
\[
|1 + \alpha_w Z^2| \geq |1 + \alpha_w \Re Z^2| = |1 + \alpha_w (K^2 - q^2)|.
\]
If we restrict \( |q| \) so that \( 1 - \alpha_w q^2 > 1/2 \) then we see that
\[
(9.8) \quad |1 + \alpha_w Z^2| \geq \frac{1}{2} (1 + 2\alpha_w K^2) \geq \frac{1}{2}
\]
for all \( Z \).

From (9.5) we have
\[
|\tilde{c}^2 - \epsilon^2 \alpha_w Z^2 - \tilde{\zeta}(\epsilon Z)| \leq C_1 \epsilon^4 |Z|^4.
\]
So let us demand that
\[
|Z| \leq \frac{\delta_1}{\epsilon}.
\]
We will specify \( \delta_1 > 0 \) in a moment. Then
\[
C_1 \epsilon^4 |Z|^4 \leq C_1 \delta_1^2 \epsilon^2 |Z|^2 = C_1 \delta_1^2 \epsilon^2 (K^2 + q^2).
\]
Of course there exists \( C_2 \) such that
\[
K^2 + q^2 \leq C_2 (1 + 2\alpha_w K^2).
\]
Thus
\[
C_1 \epsilon^4 |Z|^4 \leq C_2 C_1 \delta_1^2 \epsilon^2 (1 + 2\alpha_w K^2).
\]
Then take \( \delta_1 = \frac{1}{2\sqrt{C_1 C_2}} \) so that
\[
(9.9) \quad C_1 \epsilon^4 |Z|^4 \leq \frac{1}{4} \epsilon^2 (1 + 2\alpha_w K^2).
\]

Putting (9.7), (9.8) and (9.9) together gives, for all \( \epsilon \in (0, 1) \),
\[
(9.10) \quad |\tilde{\omega}^i(\epsilon Z)| = \frac{|\epsilon^2 \tilde{\zeta}(\epsilon Z)|}{\tilde{c}^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z)} \leq \frac{4C_1}{1 + 2\alpha_w K^2} \leq \frac{C}{1 + K^2}.
\]

Next look at
\[
\tilde{\rho}^i(Z) := \tilde{\omega}^i(Z) - \tilde{\omega}^0(Z) = -\frac{\epsilon^2 \tilde{\zeta}(\epsilon Z)}{\tilde{c}^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z)} + \frac{\tilde{c}^2}{1 + \alpha_w Z^2}.
\]
Adding zero and the triangle inequality gives:
\[
|\tilde{\rho}^i(Z)| \leq \left| \frac{\tilde{\zeta}(\epsilon Z) - \tilde{c}^2}{1 + \alpha_w Z^2} \right| + \left| \frac{\epsilon^2}{\tilde{c}^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z)} - \frac{1}{1 + \alpha_w Z^2} \right| =: I + II.
\]
The second estimate in (9.5) gives
\[ I \leq \frac{C_1 \epsilon^2 |Z|^2}{|1 + \alpha_w^2 Z|^2}. \]
Then if we assume (9.11) and apply (9.8) we have:
\[ I \leq C \epsilon^2 \frac{K^2 + q^2}{1 + 2\alpha_w K^2} \leq C \epsilon^2. \]

Next, combining fractions gives:
\[ II = \left| \bar{\zeta}(\epsilon Z) - c_w^2 + \epsilon^2 \alpha_w Z^2 \right| \]
\[ \left| c_w^2 + \epsilon^2 - \bar{\zeta}(\epsilon Z) \right| |1 + \alpha_w Z^2| \]
Using the first and third inequalities in (9.5) gives:
\[ II \leq \frac{C \epsilon^4 |Z|^4}{|1 + \alpha_w Z^2|} \]
Then if we assume (9.11) and apply (9.8) and (9.10) we have:
\[ II \leq \frac{C \epsilon^2 |Z|^4}{(1 + 2\alpha_w K^2)^2} \]
Then we see
\[ II \leq \frac{C \epsilon^2 (K^2 + q^2)^2}{(1 + 2\alpha_w K^2)^2} \leq C \epsilon^2. \]
Therefore, if (9.11) is met, we have
\[ (9.13) \quad \left| \tilde{\varpi}'(Z) - \tilde{\varpi}^0(Z) \right| \leq C \epsilon^2. \]

**Estimates far from** \( Z = 0 \): We saw in (2.18) that \( c_w^2 k^2 - \tilde{\lambda}_-(k) \geq 0 \) with equality only at \( k = 0 \). This implies that
\[ (9.14) \quad \tilde{\zeta}(k) < c_w^2 \]
for all \( k \neq 0 \) and \( k \in \mathbb{R} \). Take \( \delta_1 \) as above and put \( \tilde{\zeta}_1 := \sup_{|k| \geq \delta_1/2} \tilde{\zeta}(k) \). Because we have (9.14), we know that
\[ c_w^2 - \tilde{\zeta}_1 =: \delta_3 > 0. \]
It should be obvious that \( \delta_3 \) does not depend at all on \( \epsilon \).

Suppose that \( Z = K + iq \) with \( |K| \geq \delta_1/2 \). Then the reverse triangle inequality gives:
\[ (9.15) \quad \left| c_w^2 + \epsilon^2 - \bar{\zeta}(\epsilon Z) \right| \geq \left| c_w^2 + \epsilon^2 - \bar{\zeta}(\epsilon K) \right| - \left| \bar{\zeta}(\epsilon K) - \bar{\zeta}(\epsilon K + i\epsilon q) \right| \]
Since \( \epsilon |K| \geq \delta_1/2 \) we have
\[ (9.16) \quad \left| c_w^2 + \epsilon^2 - \bar{\zeta}(\epsilon K) \right| \geq \delta_3. \]
Then we use (9.6) to see that
\[
\left| \tilde{\zeta}(\epsilon K) - \tilde{\zeta}(\epsilon K + i\epsilon q) \right| \leq C_1 \epsilon |q|.
\]
Thus if we restrict \(|q| \leq q_{52} := \min(\delta_3/2C_1, \tau_0)\) we have
\[
(9.17) \quad \left| \tilde{\zeta}(\epsilon K) - \tilde{\zeta}(\epsilon K + i\epsilon q) \right| \leq \delta_3/2
\]
for all \(\epsilon \in (0, 1)\).

Thus if we have
\[
(9.18) \quad \Im(Z) \leq q_{52} \quad \text{and} \quad \Re(Z) \geq \delta_1/2\epsilon
\]
then (9.15), (9.16) and (9.17) give:
\[
(9.19) \quad \left| c_w^2 + \epsilon^2 - \tilde{\zeta}(\epsilon Z) \right| \geq \frac{1}{2} \delta_3.
\]
This gives
\[
|\tilde{\omega}^\epsilon(Z)| \leq C\epsilon^2 \left| \tilde{\zeta}(\epsilon Z) \right| \leq C \frac{|\tilde{\lambda}_-(\epsilon Z)|}{|Z|^2}.
\]
when we have (9.18). The uniform bound on \(\tilde{\lambda}_-\) converts this to
\[
|\tilde{\omega}^\epsilon(Z)| \leq C\epsilon^2 \left| \tilde{\zeta}(\epsilon Z) \right| \leq \frac{C}{|Z|^2}.
\]
But since we have (9.18), clearly
\[
|Z|^2 \geq K^2 + q^2 \geq \frac{1}{2} K^2 + \frac{\delta_1^2}{4\epsilon^2}.
\]
This implies
\[
(9.20) \quad |\tilde{\omega}^\epsilon(Z)| \leq \frac{C\epsilon^2}{1 + \epsilon^2 K^2} \leq \frac{C}{1 + K^2}
\]
Along the same lines we can prove
\[
(9.21) \quad |\tilde{\omega}^0(Z)| = \frac{c_w^2}{|1 + \alpha_w Z^2|} \leq \frac{C\epsilon^2}{1 + \epsilon^2 K^2}
\]
provided we have (9.18).

**Overall estimates:** Let \(q_5 := \min(q_{51}, q_{52})\). If \(\Im(Z) \leq q_5\) the observe that \(Z\) satisfies either (9.11) or (9.18). Thus putting (9.12) together with (9.20) yields
\[
|\tilde{\omega}^\epsilon(Z)| \leq \frac{C}{1 + |Z|^2}.
\]
This estimate holds for all \(\epsilon \in (0, 1)\). This is Part (ii) of the lemma and it implies Part (i). Putting (9.13) with (9.20), (9.21) and the triangle inequality gives
\[
|\tilde{\omega}^\epsilon(Z) - \tilde{\omega}^0(Z)| \leq \frac{C\epsilon^2}{1 + \epsilon^2 |Z|^2}.
\]
This estimate holds for all \(\epsilon \in (0, 1)\). This implies Part (iii) and we are done.
9.2. **Multiplier properties in R.** This subsection contains the proofs of Lemmas 11, 12 and 13. We begin with two more lemmas to prove Lemma 11.

**Lemma 32.** \( \lambda''(k) < 0 \) for \( k \in (0, \pi/2) \).

**Proof.** We find
\[
\tilde{\lambda}''(k) = -\frac{16w \sin(k) \cos(k)}{q(k)^5} q_w(\cos^2(k)),
\]
where \( q_w \) is the quadratic
\[
q_w(X) = 4w^2X^2 + (2w^3 - 4w^2 + 2w)X + (w^4 - w^3 - w + 1).
\]
The discriminant of \( q_w \) is
\[
\Delta(w) := (2w^3 - 4w^2 + 2w) - 4(4w^2)(w^4 - w^3 - w + 1) = -12w^6 + 24w^4 - 12w^2 = -12w^2(w^4 - w^2 + 1),
\]
and when \( w > 1 \),
\[
w^4 - w^2 + 1 > w^4 - 2w^2 + 1 = (w^2 - 1)^2 > 0,
\]
hence \( \Delta(w) < 0 \), and so \( q_w \) is either strictly positive or strictly negative. Since \( q_w \) has positive leading coefficient \( 4w^2 \), \( q_w \) is strictly positive, and because \( \sin(k) \cos(k) > 0 \) on \( (0, \pi/2) \), we conclude \( \tilde{\lambda}''(k) < 0 \) on \( (0, \pi/2) \).

**Lemma 33.** For all \( \delta > 0 \) there exists \( C_{\text{quad}, \delta} > 0 \) such that
\[
C_{\text{quad}, \delta} k^2 \leq c_w^2 k^2 - \tilde{\lambda} - (k) \text{ for all } k \in [\delta, \infty).
\]

**Proof.** Without loss of generality, suppose \( 0 < \delta < \pi/2 \). From the proof of Lemma 29 the function
\[
\tilde{\zeta}(k) := \begin{cases} 
\tilde{\lambda} - (k) / k^2, & k \neq 0 \\
c_w^2, & k = 0
\end{cases}
\]
is bounded, analytic, and nonnegative on \( \mathbb{R} \), and it is an easy computation to see that \( \tilde{\zeta} \) is Lipschitz as well. Next,
\[
\tilde{\zeta}'(k) = \frac{k^2 \tilde{\lambda}'(k) - 2k \tilde{\lambda} - (k)}{k^2}, k \neq 0.
\]
We will show \( k^2 \tilde{\lambda}'(k) - 2k \tilde{\lambda} - (k) < 0 \) for all \( k \in (0, \pi/2) \), which implies \( \tilde{\zeta}'(k) < 0 \) on \( (0, \pi/2) \) and therefore that \( \tilde{\zeta} \) is decreasing there. First, Taylor’s theorem gives
\[
\tilde{\lambda} - (k) = \tilde{\lambda} - (0) + \tilde{\lambda}' - (0)k + k^2 \int_0^1 (1 - t)\tilde{\lambda}'' - (sk) \, ds = k^2 \int_0^1 (1 - t)\tilde{\lambda}'' - (sk) \, ds.
\]
Then differentiating under the integral, we find
\[
\tilde{\lambda}' - (k) = 2k \int_0^1 (1 - s)\tilde{\lambda}'' - (sk) \, ds + k^2 \int_0^1 s(1 - s)\tilde{\lambda}''' - (sk) \, ds,
\]
hence
\[ k \tilde{\lambda}'_\epsilon(k) - 2 \tilde{\lambda}_\epsilon(k) = k^3 \int_0^1 s(1 - s) \tilde{\lambda}''_\epsilon(sk) \, ds < 0 \]
by Lemma 32.

So, \( \tilde{\zeta} \) is decreasing on \((0, \pi/2)\), and therefore
\[ c_w^2 = \tilde{\zeta}(0) > \tilde{\zeta}(\delta) > \tilde{\zeta}(k) \]
for \( k \in (\delta, \pi/2) \), from which
\[(9.22) \quad 0 < c_w^2 - \left( \frac{c_w^2 - \tilde{\zeta}(\delta)}{10} \right) - \tilde{\zeta}(k), \quad k \in (\delta, \pi/2). \]

The inequality \((9.22)\) remains true at \( k = \pi/2 \) since \( \tilde{\zeta}(\pi/2) = 0 \). When \( k > \pi/2 \), observe that
\[ \tilde{\zeta}(k) \leq \tilde{\lambda}_\epsilon(k) = \frac{4 \tilde{\lambda}_\epsilon(k)}{\pi^2} = \frac{8}{\pi^2} = \tilde{\zeta}(\pi/2) \]
by \((2.5)\), thus
\[ c_w^2 - \left( \frac{c_w^2 - \tilde{\zeta}(\delta)}{10} \right) - \tilde{\zeta}(k) \geq c_w^2 - \left( \frac{c_w^2 - \tilde{\zeta}(\delta)}{10} \right) - \tilde{\zeta}(\pi/2) > 9c_w^2/10 - \tilde{\zeta}(\delta)/10 - \tilde{\zeta}(\pi/2) > 0 \]
since \( w > 1 \). So, we take \( C_{\text{quad,} \delta} = (c_w^2 - \tilde{\zeta}(\delta))/10 \).

**Proof.** (of Lemma 11) We begin with some comments on our choice of \( \epsilon_{12} \). From \((2.8)\) in Part (vi) of Lemma 2, we have
\[(9.23) \quad m_\epsilon(w) := \sqrt{\frac{2w}{c_w^2 + 1}} \leq \epsilon K_\epsilon \leq \sqrt{2 + 2w} \frac{c^*}{c_w} =: m^*(w), \quad 0 < \epsilon < 1. \]

By taking \( \epsilon_* = \epsilon_*(w) \) close to 0, we will have
\[(9.24) \quad K_\epsilon \geq 2 \quad \text{and} \quad m_\epsilon(w) - \epsilon_*/2 > 0. \]

Consequently,
\[(9.25) \quad K_\epsilon + t \geq 1 \quad \text{and} \quad \epsilon K_\epsilon + \epsilon t \geq m_\epsilon(w) - \epsilon_* \quad \text{for} \ |t| \leq 1, 0 < \epsilon < \epsilon_. \]

With \( \epsilon_4 \) as in Lemma 29, set \( \epsilon_{11} = \min\{\epsilon_*, \epsilon_4\} \). Then Lemma 29 gives \( C > 0 \) such that
\[ \sup_{0 < \epsilon < \epsilon_{11}} |\tilde{\omega}^\epsilon(K)| \leq \frac{C}{1 + K^2}, \quad K \in \mathbb{R}. \]

Then for each \( k \in \mathbb{Z} \),
\[ \sup_{0 < \epsilon < \epsilon_{11}} |\tilde{\omega}^\epsilon(K_\epsilon + t)| = \sup_{0 < \epsilon < \epsilon_0} |\tilde{\omega}^\epsilon((K_\epsilon + t)k)| \leq \frac{C}{1 + ((K_\epsilon + t)k)^2}. \]
Using (9.25), we have

\[
\frac{C}{1 + ((K_\epsilon + t)k)^2} \leq \frac{C}{1 + k^2}
\]

for all \(k \in \mathbb{Z}\). This proves the first estimate (4.22) for the multiplier \(\tilde{\omega}^{\epsilon, K_\epsilon + t}\).

We prove the Lipschitz estimate (4.23) only when \(k \geq 1\) as when \(k = 0\) the left side of this inequality is zero, and evenness takes care of \(k \leq -1\). Fix \(0 < \epsilon < \epsilon_{12}, k \geq 1\), and \(|t| \leq 1\) and abbreviate \(K := \epsilon(K_\epsilon + t)k\) and \(\dot{K} := \epsilon(K_\epsilon + \dot{t})k\) to find

\[
\omega^{\epsilon, K_\epsilon + t}(k) - \omega^{\epsilon, \dot{K}}(k) = \frac{\epsilon^2 \tilde{\lambda}_-(K)}{(c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K)} - \frac{\epsilon^2 \tilde{\lambda}_-(\dot{K})}{(c_w^2 + \epsilon^2)\dot{K}^2 - \tilde{\lambda}_-(\dot{K})}
\]

\[
+ \frac{\epsilon^2 \tilde{\lambda}_-(\dot{K})(c_w^2 + \epsilon^2)\dot{K}^2 - \tilde{\lambda}_-(\dot{K}) - \epsilon^2 \tilde{\lambda}_-(K)((c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K))}{((c_w^2 + \epsilon^2)\dot{K}^2 - \tilde{\lambda}_-(\dot{K}))(c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K))}
\]

Call the last two terms above \(I\) and \(II\). Set \(\delta = m_*(w) - \epsilon_*\) and invoke Lemma 33 to find \(C_{\text{quad}, \delta} > 0\) such that

\[
(9.26) \quad C_{\text{quad}, \delta} K^2 \leq c_w^2 K^2 - \tilde{\lambda}_-(K) \leq (c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K)
\]

for all \(K \in [\delta, \infty)\). By (9.25) we have \(\epsilon(K_\epsilon + t)k \geq \delta\) for all \(0 < \epsilon < 1, |t| \leq 1, k \geq 1\). Then using the additional estimates Lip(\(\tilde{\lambda}_-\)) \(\leq 2\) from (2.5) and \(K_\epsilon + t \geq 1\), which is (9.25), we estimate \(I\) by

\[
|I| \leq \left| \frac{\epsilon^2 (\tilde{\lambda}_-(K) - \tilde{\lambda}_-(\dot{K}))}{(c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K)} \right| \frac{2\epsilon K - \dot{K}}{C_{\text{quad}, \delta} K^2} \leq \frac{2\epsilon |K - \dot{K}|}{C_{\text{quad}, \delta} K^2} \leq 2\epsilon_{11} |t - \dot{t}|.
\]

Next, we rewrite \(II\) as

\[
II = \frac{\epsilon^2 (c_w^2 + \epsilon^2)\tilde{\lambda}_-(\dot{K})(\dot{K}^2 - K^2) + \epsilon^2 \tilde{\lambda}_-(\dot{K})(\tilde{\lambda}_-(K) - \tilde{\lambda}_-(\dot{K}))}{((c_w^2 + \epsilon^2)\dot{K}^2 - \tilde{\lambda}_-(\dot{K}))(c_w^2 + \epsilon^2)K^2 - \tilde{\lambda}_-(K))},
\]

hence

\[
|II| \leq \frac{\epsilon^2 (c_w^2 + \epsilon^2)\tilde{\lambda}_-(\dot{K})(\dot{K}^2 - K^2)}{C_{\text{quad}, \delta} K^2 |\dot{K}|^2} + \frac{\epsilon^2 |\tilde{\lambda}_-(\dot{K})(\tilde{\lambda}_-(K) - \tilde{\lambda}_-(\dot{K}))|}{C_{\text{quad}, \delta} K^2 |\dot{K}|^2}.
\]

Labeling these two terms as \(III\) and \(IV\), we find

\[
|III| \leq \frac{2\epsilon^4 (c_w^2 + \epsilon^2)k^2(|K_\epsilon + t| + |K_\epsilon + \dot{t}|)|t - \dot{t}|}{C_{\text{quad}, \delta} K^2 |K_\epsilon + t|^2 |K_\epsilon + \dot{t}|^2}.
\]
Together, the estimates on $I$, $III$, and $IV$ give (4.23) for $k \geq 1$, which satisfies our purposes.

**Proof. (of Lemma 12)**

(i) Since $\overline{\Pi}_2(\pm 1) = 0$ and $\widetilde{\zeta}_{w_1}(0) = 2 + 2w$, we show

\[(9.27)\quad 0 < \inf_{0 < t < \epsilon_1} \frac{1}{|t| \geq 2} |\widetilde{\zeta}_{w_1}(\epsilon(K_k + t)k)| =: m_\zeta\]

for an appropriate $\epsilon_1 > 0$ and set

\[(9.28)\quad C_{\zeta_{\min}} = \min\{m_\zeta, 2 + 2w\} \quad \text{and} \quad C_{\zeta_{\max}} = C^{-1}_{\zeta_{\min}}.\]

We begin with some seemingly unrelated calculations which result in our choice of $\epsilon_1$. Set

\[f(\gamma, w) := -(1 + \gamma)^2 \left(\frac{4w^2}{3w + 1}\right) + 2 + 2w \quad \text{and} \quad g(w) := \lim_{\gamma \to 1^-} f(\gamma, w) = -\frac{16w^2}{3w + 1} + 2 + 2w.\]

Elementary algebra shows that for $w > 1$, $g(w) < 0$ if and only if $5w^2 - 4w - 1 > 0$, and it is the case that this quadratic is positive on $(1, \infty)$. So, we may find some $\gamma_\ast = \gamma_\ast(w) \in (0, 1)$ such that $f(\gamma_\ast, w) < 0$.

Let $\epsilon_1 = \epsilon_{12}(\gamma_\ast, w) > 0$ be so small that the inequalities (9.24) from the proof of Part (i) of Lemma 11 above hold with $\epsilon_\ast = \epsilon_1$. Furthermore, require $\epsilon_1$ to satisfy

\[(9.29)\quad 2m_\ast(w) - 2\epsilon_\ast \geq (1 + \gamma_\ast)m_\ast(w),\]

and suppose that $\epsilon_1$ is small enough that $|c_\epsilon - c_w| < \delta$ for $0 < \epsilon < \epsilon_1$, where $\delta$ is from Lemma 25.

Then for $k \geq 2$, $|t| \leq 1, 0 < \epsilon < \epsilon_\ast$, we have

\[
\begin{align*}
\epsilon(K_k + t)k &= \epsilon K_k(k - 1) + \epsilon tk + \epsilon K_k \\
&\geq m_\ast(w)(k - 1) - \epsilon_\ast k + m_\ast(w) \\
&= (m_\ast(w) - \epsilon_\ast)k \\
&\geq 2(m_\ast(w) - \epsilon_\ast)k \quad \text{and} \quad \epsilon(K_k + t)k \leq m_\ast(w)(k + \epsilon_\ast) = m_\ast(w)(k + 1)
\end{align*}
\]
\[ \geq (1 + \gamma_s)m_*(w) \text{ by } (9.29). \]

Now, observe that \( \xi_\epsilon \) is increasing on \((0, \infty)\) whenever \( c \geq c_w \) as from \((2.6)\), when \( k > 0 \) we have
\[
(9.30) \quad \xi_\epsilon'(k) = 2c_\epsilon^2 k - \lambda_+(k) \geq 2c^2_w k - \lambda_+(k) \geq 2c^2_w |k| - |\lambda_+(k)| \geq 0.
\]

Then the work above shows
\[
\tilde{\xi}_\epsilon (\epsilon(K_\epsilon + t)k) \leq \tilde{\xi}_{c_\epsilon} (\epsilon(K_\epsilon + t)k)
\leq \tilde{\xi}_{c_\epsilon} ((1 + \gamma_s)m_*(w))
= \tilde{\xi}_{c_\epsilon} (c^2_\epsilon \omega(1 + \gamma_s)m_*(w))^2 + \lambda_+(1 + \gamma_s)m_*(w))
\leq \tilde{\xi}_{c_\epsilon} (1 + \gamma_s)m_*(w))^2 + 2 + 2w
\leq f(\gamma_s, w) < 0.
\]

Thus \((9.27)\) follows with \( 0 < |f(\gamma_s, w)| \leq \mu_\lambda \).

(ii) To prove the Lipschitz estimate \((4.25)\), note that it already holds when \( k = 0 \), so for \( k \geq 2 \) set \( K = \epsilon(K_\epsilon + t)k \), \( \tilde{K} = \epsilon(K_\epsilon + \tilde{t})k \) and compute
\[
\left| \frac{1}{\xi_\epsilon_\epsilon(K)} - \frac{1}{\xi_\epsilon_\epsilon(\tilde{K})} \right| \leq \left| \frac{(c^2_\omega + \epsilon^2)\tilde{K}^2 - \lambda_+(\tilde{K}) - ((c^2_\omega + \epsilon^2)K^2 - \lambda_+(K))}{\xi_\epsilon_\epsilon(K)\xi_\epsilon_\epsilon(\tilde{K})} \right|
\leq \left( \frac{c^2_\omega + \epsilon^2|K^2 - \tilde{K}^2|}{\xi_\epsilon_\epsilon(K)\xi_\epsilon_\epsilon(\tilde{K})} \right) + \left( \frac{\tilde{\lambda}_+(K) - \tilde{\lambda}_+(\tilde{K})}{\xi_\epsilon_\epsilon(K)\xi_\epsilon_\epsilon(\tilde{K})} \right)
\]

Call the two terms above \( I \) and \( II \). By choice of \( \epsilon_{12} \) above, Lemma \( 25 \) furnishes \( C, R > 0 \) such that when \( k \geq R \) and \( 0 < \epsilon < 2 \), then
\[
(9.31) \quad \frac{1}{|\tilde{\xi}_\epsilon_\epsilon(k)|} \leq \frac{1}{Ck^2}
\]

Since \( m_*(w) - \epsilon_{12} > 0 \) by \((9.24)\), we may set \( R_* = R/(m_*(w) - \epsilon_{12}) \) to see that when \( k > R_*, \) then
\[
R < (m_*(w) - \epsilon_{12})k \leq \epsilon(K_\epsilon + t)k.
\]

**Estimates when \( 2 \leq k \leq R_* \).** With \( C_{\xi_{\min}} \) as in \((9.28)\), we bound
\[
|I| \leq \frac{\epsilon^2_{12}(c^2_\omega + \epsilon^2)|\tilde{K} + K||\epsilon|k||t - \tilde{t}|}{C^2_{\xi_{\min}}} = \frac{\epsilon^2_{12}(c^2_\omega + \epsilon^2)\epsilon k^2|2\epsilon K_\epsilon + \epsilon t + \epsilon \tilde{t}||t - \tilde{t}|}{C^2_{\xi_{\min}}}
\leq \left( \frac{2\epsilon^3_{12}R^2_\epsilon(c^2_\omega + \epsilon^2)(\beta(w) + \epsilon_{12})}{C^2_{\xi_{\min}}} \right) |t - \tilde{t}|
and using $\text{Lip}(\tilde{\alpha}_+)^2 \leq 2$,

$$|II| \leq \frac{2\epsilon^3 R^*}{C^2 \xi_{\min}} \leq \frac{2\epsilon|k||t - \hat{t}|}{C^2 \xi_{\min}} \leq \left( \frac{2\epsilon^3 R^*}{C^2 \xi_{\min}} \right) |t - \hat{t}|.$$ 

**Estimates when $k > R^*$.** Using \[\text{(9.31)}\] we have

$$|I| \leq \frac{\epsilon^2 c_w^2 \epsilon^2 |K + \hat{K}| |K - \hat{K}|}{C^2 |K|^2 |\hat{K}|^2} = \frac{\epsilon^4 (c_w^2 + \epsilon^2) K^2 |(K_\epsilon + t) + (K_\epsilon + \hat{t})||t - \hat{t}|}{C^2 \epsilon^4 k^4 (K_\epsilon + t)^2 (K_\epsilon + \hat{t})^2} \leq \left( \frac{2\epsilon^2 (c_w^2 + \epsilon^2)}{C^2 R^*_t} \right) |t - \hat{t}|,$$

since by \[\text{(9.24)}\]

$$\frac{|(K_\epsilon + t) + (K_\epsilon + \hat{t})|}{(K_\epsilon + t)^2 (K_\epsilon + \hat{t})^2} \leq 2.$$

Next, adding and subtracting $K\tilde{\zeta}(\hat{K})$ and using the triangle inequality in the numerator of II and \[\text{(9.31)}\] in the resulting denominators gives

$$|II| \leq \frac{\epsilon^2 |K^2 \tilde{\zeta}(K) - \hat{K}^2 \tilde{\zeta}(\hat{K})|}{C^2 |K|^2 |\hat{K}|^2} \leq \frac{\epsilon^2 |\tilde{\zeta}(K) - \tilde{\zeta}(\hat{K})| |K^2 - \hat{K}^2|}{C^2 |K|^2 |\hat{K}|^2} \leq \frac{\epsilon^2 \text{Lip}(\tilde{\zeta}) |K - \hat{K}|}{C^2 |\hat{K}|^2} + \frac{\epsilon^2 c_w^2 |K + \hat{K}| |K - \hat{K}|}{C^2 |K|^2 |\hat{K}|^2} \leq \frac{\epsilon^3 |k| \text{Lip}(\tilde{\zeta}) |t - \hat{t}|}{C^2 \epsilon^2 |K_\epsilon + t||^2 |k|} + \frac{\epsilon^2 c_w^2 \epsilon^2 k^2 |(K_\epsilon + t) + (K_\epsilon + \hat{t})||t - \hat{t}|}{C^2 \epsilon^4 k^4 (K_\epsilon + t)^2 (K_\epsilon + \hat{t})^2} \leq \left( \frac{\text{Lip}(\tilde{\zeta}) \epsilon_{12} + 2c_w^2}{C^2} \right) |t - \hat{t}|$$

by reasoning similar to that above. 

\[\square\]

**Proof.** (of Lemma \[\text{13}\]) Taylor’s theorem and some straightforward algebra imply

$$\tilde{\zeta}_{\epsilon_\tau}(\epsilon K_\epsilon + \tau) - \tilde{\zeta}_{\epsilon_\tau}(\epsilon K_\epsilon) \tau = \epsilon^2 \left( \int_0^1 (1 - s) \tilde{\lambda}_{\epsilon_\tau}''(\epsilon K_\epsilon + s \tau) \, ds - (c_w^2 + \epsilon^2) \right)$$

Set

$$R_\epsilon(\tau) := \int_0^1 (1 - s) \tilde{\lambda}_{\epsilon_\tau}''(\epsilon K_\epsilon + s \tau) \, ds - (c_w^2 + \epsilon^2).$$

The estimates \[\text{(4.27)}\] for $R_\epsilon$ follow directly from properties of $\tilde{\lambda}_{\epsilon_\tau}''$ so long as $\epsilon$ is bounded. 

\[\square\]
10. Conclusions/Questions/Future Directions

We have considered a diatomic lattice where the only spatially variable material property was the particles’ masses. We also took a very basic form for the spring force \( F_s(r) = -k_s r - b_s r^2 \). We are confident that the results here can be extended to much more general situations, be it including more complicated and spatially heterogeneous springs or assuming that the number of “species” of masses and springs is greater than two, i.e. a polymer lattice.

As mentioned above, we do not yet have lower bounds for the size of the periodic part’s amplitude, though the methods used in [Sun91] provide a roadmap for establishing them. Again, we expect that those methods will show that the periodic part is genuinely non-zero, at least for almost all \( \epsilon \). But if the periodic part is non-zero then necessarily the total mechanical energy of the nanopteron solution will be infinite. This stands in stark contrast to the solitary waves for monatomic FPUT, which are not only finite energy but also constrained minimizers of an appropriate related energy functional [FW94].

Nonetheless we contend that the nanopteron solutions we construct are essential for understanding the long time behavior of small amplitude long wave solutions for diatomic FPUT. It is known that the monatomic solitary waves are asymptotically stable [FP02] [FP04] and, moreover, there are stable multisoliton-like solutions [HW09] [Miz11]. It is widely held that all small, long wave initial conditions for monatomic FPUT will satisfy that the soliton resolution conjecture, which is to say that they will converge to a linear superposition of well-separated solitary waves plus a dispersive tail, also called “radiation.”

But if, as we expect, there are no localized traveling long wave solutions in diatomic FPUT then clearly some other asymptotic behavior takes place. We know, by virtue of the approximation results in [GMWZ14] and [CBCPS12], that long wave initial data for (1.3) remains close to suitably scaled solutions of the KdV equation for very long times. Specifically for times \( t \) up to \( O(1/\epsilon^3) \) where \( \epsilon \) is consistent with its meaning here. And since the soliton resolution conjecture is known to be true (via integrability) for KdV that means we can expect the solution of diatomic FPUT to resolve, at least temporarily, into a sum of sech\(^2\) like solitary waves. But on time scales beyond this those approximation theorems tell us nothing.

There are any number of possibilities for what happens afterwards. One possibility, which we favor, is that there is a very slow “leak” of energy from the acoustic branch into the optical branch that will eventually erode the solution into nothing but radiation. That is to say, we conjecture the existence of metastable solutions which look for very long times like localized solitary waves but eventually converge to zero. Another possibility is that there is a heretofore unknown finite energy coherent structure with a more complicated temporal behavior to which the solution converges—for instance something akin to the traveling breathers that exist in modified KdV or a localized quasi-periodic solution. Yet another scenario is that there are a discrete set of choices for \( \epsilon \) where the ripple vanishes. These waves would then, in a rough sense, quantize the possible behavior as \( t \) goes to infinity.

These questions are likely very difficult to settle. Note that the time scales are so long that only very careful numerics performed on very large domains will shed any light. And so, as we stated in the introduction, we feel our work here raises many interesting questions.
