Authors’ contributions

This work was carried out in collaboration among all authors. Author SAMS contributed to the analysis, literature review and formatting of the article. Author IFM contributed to the supervision of the analysis, writing of the article and review of language and style. Author BML contributed to the collection of the material, sample preparation and analysis. Authors RAS and JAFM contributed to the review, editing of the article, the verification, validation of the methods and analysis being used in the experiments. All authors read and approved the final manuscript.

1. INTRODUCTION

Arecaceae or Palm families, constituted by about 2400 species distributed by various tropical and subtropical areas of the planet [1] as only the Neotropic areas in Africa and Asia [2] as well as the Neotropic regions of the Amazon Region and Central America [3] where more than 150 species of palm trees are found [4].

Among the palms of this family, it is worth mentioning the Patauá (Oenocarpus bataua Mart.), which has a concrescence with presence in the Amazon region, with famous traditional people, presenting great economic potential, serving as a source of food, as well as preparing medicines [5,6]. This species considered an oligarchic species, exceeding its natural production at 11.1 t ha⁻¹ year [7]. The Patauá fruit has a purple color and weighs between 6-8 grams [8]. Patauá, presents numerous food applications, highlighting or Patauá wine, being an abundant source of rent, as well as a production of oil, which shows flavor and properties similar to olive oil, as well as manufacturing of soda and ice cream [9]. The oil extracted from Patauá presents massive quantities of unsaturated fatty acids [10]. The most important characteristic of this type of oil, and a high concentration of oleic acid and low level of palmitic acid, characteristic of other palm oils, as well as presenting applications to the cosmetics industry and not treating certainties [11]. Since there is work related to the fruit of Patauá a palm, this study aimed to study the chemical, nutritional composition and bioactive molecules in pulp and Patauá seed with occurring in the state of Roraima, in the Northern Amazon of Brazil.

2. MATERIALS AND METHODS

2.1 Collection and Processing of Samples

The Patauá samples were collected in Rorainópolis city in the state of Roraima (Brazil) and were taken to the Chemistry laboratory of the Federal Institute of Roraima, where previously selected were those that had an acceptable conservation state for consumption, and the samples were separated. Seed pulps and freezing at -80°C and lyophilized. The lyophilized material was sieved between 30-40 Mesh and stored in the dark until it was time for analysis.

2.2 Mineral Analysis

The extraction of minerals in the different parts of the fruit was done according to the methodology described by EMBRAPA [12], which uses the perchloric nitric digestion (3:1) in a TECNAL model TE 0079 digester block, washed with distilled water until 25 mL for subsequent analysis. Calcium (Ca), magnesium (Mg), iron (Fe), copper (Cu), zinc (Zn), manganese (Mn), and aluminum (Al) were determined by flame atomic absorption spectrophotometry (FAAS). Shimadzu AA-7000, coupled with ASC-7000 auto sample. Calibration was performed with standard solutions prepared from 1000 mgL⁻¹. Qhemis High Purity PACU 1000-0125 commercial standards according to the specific conditions of each element (Table 1).
In the case of sodium (Na), it was determined in the same equipment, but in atomic emission mode. Potassium (K) was evaluated by flame photometry using the Digimed DH-62 Flame Photometer, calibrated using a Digimed standard solution with a concentration range of 2 - 100 mg L\(^{-1}\). For the determination of phosphorus (P) and boron (B), the Ultraviolet-visible spectrophotometry technique (SHIMADZU model UV-1800 equipment) was applied using the methodology of EMBRAPA [12], which the colorimetric reaction was done by ammonium molybdate ((NH\(_4\))\(_2\)MoO\(_4\)). In the case of P, a blue complex was formed, where the readings were taken at \(\lambda = 660\) nm; In the case of B, a complex was formed with yellow azomethine-H and absorbed light at \(\lambda = 460\) nm.

### 2.3 Characterization of Bioactive Molecules

The determination of total phenolic compounds (CFT) was being used gallic acid as a reference standard and absorbance readings in UV-VIS Photonics spectrophotometer at 765 nm [13]. The results were reported as GAE in 100 g\(^{-1}\) of the sample. The antioxidant activity was performed using two methodologies: on the one hand, the 1,1-diphenyl-2-picylhydrazine (DPPH) absorption method was used absorbance readings at 515 nm [14]. The second method to evaluate total antioxidant activity was by the process of reducing \(Fe^{3+} \rightarrow Fe^{2+}\) [15].

The absorbance readings made the concentration of total carotenoids, which were taken on UV-VIS molecular absorption spectrophotometer at 661 nm, 644 nm, and 470 nm, respectively [16]. Finally, vitamin C quantification was performed by UV-visible molecular spectrophotometry and recorded at 545 nm [17,18].

### 3. RESULTS AND DISCUSSION

#### 3.1 Mineral Analysis

Minerals are essential nutrients for the body that cannot be synthesized and are incorporated into the diet [19], consisting of inorganic substances that help regulate body functions [20]. Table 2 shows the results of macro and micro minerals in the Patauá pulp and seed, performed by different spectrophotometric techniques.

| Element | Technique | \((\lambda)\) nm | Calibration Line |
|---------|-----------|------------------|-----------------|
| Ca      | FAAS      | 422.70           | y= 0.0092 x - 0.0005 \(r^2 = 0.999\) |
| Mg      | FAAS      | 285.21           | y= 0.2353 x - 0.0658 \(r^2 = 0.997\) |
| P       | UV-Vis    | 660.00           | y= 0.2181 x - 0.0005 \(r^2 = 0.999\) |
| K       | FAAS      | 766.50           | y= 0.1231 x - 0.0013 \(r^2 = 0.993\) |
| S       | UV-Vis    | 420.00           | y= 0.0213 x - 0.0012 \(r^2 = 0.998\) |
| Fe      | FAAS      | 248.33           | y= 0.0399 x - 0.0067 \(r^2 = 0.996\) |
| Zn      | FAAS      | 213.80           | y= 0.0600 x - 0.0171 \(r^2 = 0.991\) |
| Mn      | FAAS      | 279.48           | y= 0.0282 x + 0.0041 \(r^2 = 0.999\) |
| Cu      | FAAS      | 324.75           | y= 0.0512 x - 0.0099 \(r^2 = 0.997\) |
| Na      | EAS       | 589.00           | y= 1.0000 x + 0.0005 \(r^2 = 0.999\) |
| Al      | FAAS      | 309.30           | y= 0.0088 x + 0.0005 \(r^2 = 0.998\) |
| B       | UV-Vis    | 460.00           | y= 0.0357 x + 0.0002 \(r^2 = 0.999\) |
| Co      | FAAS      | 240.73           | y= 0.0286 x - 0.0066 \(r^2 = 0.997\) |

FAAS = Flame Atomic Absorption Spectroscopy. EAS = Flame Atomic Emission Spectroscopy. UV-Vis= UV-visible molecular spectrophotometry

#### Table 2. Mineralogical composition of Patauá pulp and seed

|          | Ca   | K     | Mg    | Na   | P   |
|----------|------|-------|-------|------|-----|
| **Pulp** |      |       |       |      |     |
| Mg       | 2.35 ± 0.11 | 2.17 ± 0.07 | 41.23 ± 0.12 | 71.21 ± 0.02 | 41.23 ± 0.12 |
| **Seeds** | 0.71 ± 0.04 | 3.52 ± 0.04 | 48.31 ± 0.07 | 84.21 ± 0.02 | 1.17 ± 0.02 |
| **Microminerals mg 100 g\(^{-1}\)** | | | | | |
| B       | 0.37 ± 0.04 | 0.11 ± 0.01 | 1.84 ± 0.02 | 0.61 ± 0.09 | 0.97 ± 0.12 |
| Co      | 0.22 ± 0.02 | 0.49 ± 0.07 | 0.91 ± 0.07 | 1.10 ± 0.03 | 0.21 ± 0.07 |

Average value of three repetitions and standard deviation at 95%
Among the macro-minerals Table 2, sodium and magnesium concentrations with better concentrations for seeds than for pulps stand out, with a value of 84.21 mg, 100 g\(^{-1}\) sodium, 48.31 mg 100 g\(^{-1}\) of magnesium for the seed. Another of the macro-minerals whose concentration is significant in Patauá is the phosphorus, being highly superior in the pulp (41.23 ± 0.12 mg 100 g\(^{-1}\)) compared to the seed. Phosphorus is an element that is synthesized in the body and is being found in the form of inorganic or organic phosphorus when it is covalently linked to other biomolecules such as proteins, sugars, and other cellular compounds [21].

On the other hand, the other two macro-minerals found in Patauá pulp and seed were, firstly, Ca, where the concentration was higher in the pulp with a value of 2.35 mg 100 g\(^{-1}\) and, secondly, potassium with higher value in seed 3.52 mg 100 g\(^{-1}\). Calcium consumption is of vital importance to humankind since it is the main constituent of bones, as well as involved in intracellular regulation of different tissues [22]. On the other hand, potassium is another of the vitally important elements for the organism since it is responsible, among other functions, for maintaining the hydroelectric balance in cells along with sodium [23]. Mineral requirements vary between 4-15% of body weight, with 50% corresponding to calcium, 25% to phosphorus, and another 25% corresponding to other minerals such as magnesium, sodium, potassium, and copper [24].

The microminerals determined in this work (Table 2), were B, Cu, Fe, Mn, and Cu, they are necessary for health since their deficiencies are related to different diseases [25]. These include iron concentrations in the pulp (1.84 mg 100 g\(^{-1}\)) and zinc in the pulp with 0.97 mg 100 g\(^{-1}\). Iron is one of the micronutrients of great importance for the organism. The iron content of 3-5 grams in the body is divided into two categories: the one belonging to functional compounds and the other corresponding to the iron stored in the hepatocytes and cells of the reticulum-system-endothelial form of ferritin and hemosiderin [26] being daily iron recommendations for the organism of 11 mg day\(^{-1}\) (men), and 15 mg day\(^{-1}\) for women [27]. Zinc is an element distributed in the body in small proportions in concentrations ranging from 1.5 to 2.5 grams [28], and is an element implicated in the proper functioning of all cells in the body, being essential especially for the development of the immune system [29]. Manganese had higher concentrations for the seed than for the Patauá pulp being an essential trace element that participates in different metabolic reactions, involved in immunological responses and regulation of ATP synthesis, as well as crucial enzymatic reactions [30]. Boron is another of the elements identified in Patauá with a higher concentration in the pulp with 0.37 mg 100 g\(^{-1}\), being of great importance for the organism in bone growth, prevention of arthritis as well as implicated in hormonal regulation processes with a daily intake of 3 mg day\(^{-1}\) [31].

### 3.2 Bioactive Molecules

Table 3 shows the results of total phenolic compounds, antioxidant activity, total carotenoids and ascorbic acid for Patauá pulp and seeds.

Total phenolic compounds measured in gallic acid equivalents per gram of sample, using standard gallic acid reference standard, were higher in seed with a concentration of 356.12 ± 0.12 mg GAEg g\(^{-1}\) than for the pulp with a level of 321.03 ± 0.43 mg GAEg g\(^{-1}\). According to the classification for phenolic compounds [32], they present a high concentration of phenolic compounds whose samples are over 500 mg GAEg g\(^{-1}\), and according to this classification, the pulp and Patauá seed, have a high level of phenolic compounds. Antioxidant activity, measured by the DPPH technique and iron reduction method, showed higher antioxidant activity for the seed than for the pulp with both evaluated methods. The results obtained with this work are close to those obtained by Rezaire et al. [33], who studies extracts from Euterpe oleracea with GAE concentrations of 306.6 ± 7.4 mg GAEg g\(^{-1}\) and antioxidant activity values determined by different methods within those surveyed in this work. As with other widely studied palm trees in this family, Euterpe oleracea has an interesting antioxidant potential, especially in vitro, and its antioxidant potential, which is related to the polyphenolic compounds such as anthocyanins (water-soluble pigments, responsible for the color purple) as well as other flavonoids [34].

The concentration of carotenoids in Patauá stands out, whose concentration is higher for seed than for pulp (Table 3), being a group of precursor bioactive molecules of vitamin E. The values obtained for carotenoids were 0.26 mg mL\(^{-1}\) for the pulp and these values were higher
for the seed with a concentration of 2.52 mg mL⁻¹. Other fruits of the same family, such as the Astrocaryum aculeatum pulp case, presented carotenoid levels between 3.5-4.3 mg 100 g⁻¹ [35] and 0.4 mg 100 g⁻¹ for Attalea maripa [36]. Another type of compound with antioxidant activity is vitamin C, which was detected at low concentrations in Patauá pulp and seed Table 3, which its deficiency can cause scurvy [37].

4. CONCLUSION

In this work, it was placed the biotechnological importance of this Amazon palm in terms of its mineralogical composition, as well as the characterization of bioactive molecules, especially the phenolic compounds in the disposable parts such as the seed, a disposable part of the fruit that could be of interest to the recovery bioactive molecules containing these bio-residues at industrial level. Also, noteworthy are carotenoids, which can be used in the pharmaceutical and cosmetic industry. It is a species still little explored and can be used as a raw material in the food industry, since until now its use is limited to the local populations of the Amazon.
