Abstract

Sanskrit (samskrta) enjoys one of the largest and most varied literature in the whole world. Extracting the knowledge from it, however, is a challenging task due to multiple reasons including complexity of the language and paucity of standard natural language processing tools. In this paper, we target the problem of building knowledge graphs for particular types of relationships from samskrta texts. We build a natural language question-answering system in samskrta that uses the knowledge graph to answer factoid questions. We design a framework for the overall system and implement two separate instances of the system on human relationships from mahabharata and ramayana, and one instance on synonymous relationships from bhavaprakasha nighantu, a technical text from ayurveda. We show that about 50% of the factoid questions can be answered correctly by the system. More importantly, we analyse the shortcomings of the system in detail for each step, and discuss the possible ways forward.

1 Introduction and Motivation

Sanskrit (IAST1: samskrta, Devanagari: संस्कृत) is one of the most ancient and richest languages in the world. Its literature boasts of text spanning every facet of life and contains works on mathematics, arts, sciences, religion, philosophy, etc. Unfortunately, the large volume of such works and the relative lack of proficiency in the language have kept treasures in those text hidden from the common man. Unraveling information from these texts in a targeted and systematic manner can not only help in enhancing the knowledge systems but can also revive an interest in the language.

Many of these texts are technical in nature, prime examples of which include ayurveda (आयुर्वेद) texts such as bhavaprakasha (भावप्रकाश). The nighantu (निघण्टु) portion of bhavaprakasha is compiled as a glossary of the various substances (dravya, द्रव्य) and their properties (guna, गुण). Although the information is generally provided in a format that enables scholars to study and analyse it systematically, the large volume of such texts makes it harder for any individual to extract all the information. An automated system can, therefore, greatly aid this processing of information. However, to the best of our knowledge, there does not exist any system that can query this knowledge trove directly and automatically.

While it can be argued that English translations of bhavaprakasha nighantu are available, and building information retrieval (IR) systems for it is a routine for today’s IR/NLP tools, there are two main shortcomings of it. First, there are many such nighantu texts and translations in English are available for only a minuscule number of them. Second, and more importantly, many of the translations of samskrta texts had been done without a proper understanding of the context and culture in which they were composed in the first place. They may had been forced to use English words and phrases that are not a true reflection of the spirit of the original

---

1Entire paper uses the IAST encoding scheme for writing Sanskrit words in romanized format. https://en.wikipedia.org/wiki/International_Alphabet_of_Sanskrit_Transliteration
meaning. A notable case in point, as mentioned by Swami Vivekananda himself, is the word śraddhā (श्रद्धा), for which the English translation “regards” is not enough.

Thus, it is always best to rely on the original language. The need of the hour, hence, is to use natural language processing (NLP) of samskṛta itself to understand the texts in samskṛta.

Our aim in this work is to take the first step towards a concrete NLP task, namely, natural language question-answering in samskṛta. In particular, we aim to design a framework that processes samskṛta texts, extracts the information in it, and stores it in a format that can be queried using questions posed in samskṛta.

We propose to store the knowledge base (KB) in a knowledge graph (KG) format. KGs have a rich structure and store the information in the form of entities (as nodes) and relationships (as edges between the nodes). The edges are directed, and both the nodes and edges can store labels describing their attributes. There are multiple off-the-shelf tools available for storing and querying KGs, including graph databases\(^2\), Property Graphs\(^3\), Resource Description Framework (RDF) (Lassila et al. (1998)), Gremlin queries\(^4\), SPARQL queries\(^5\), etc. The popularity of KBs such as YAGO (Suchanek et al. (2007)), DBpedia (Auer et al. (2007)) and Freebase (Bollacker et al. (2008)) is a testament to their success.

We also propose question-answering as a concrete example of the use of such KGs and a way of measuring the effectiveness of the system. Various online question-answering fora such as Quora\(^6\) and quizzes serve as a motivation. We particularly choose the two epics of India, namely, mahābhārata and rāmāyaṇa, categorized as itihāsa in samskṛta literature, and questions on human relationships within them, as examples for our framework due to their popularity and ease of establishment of the ground truth. We also work with bhāvaprakāśa nighaṇṭu to highlight the usage for technical texts.

The framework brings to the fore multiple challenges. First, the state of the art of natural language processing in Indian languages, unfortunately, is not as advanced as that in English or some other European languages. Indian languages, and in particular samskṛta, are morphologically richer. Therefore, tasks such as lemmatization and parts-of-speech tagging are harder and more error-prone in these languages. Second, some technical texts use their own jargon where certain words may be used in a specific meaning. For example, aṣṭādhyāyī, a work on samskṛta grammar by pāṇini uses specific combinations of grammatical cases (vibhakti) to denote which action is to be performed.\(^7\) Third, names in samskṛta are meaningful words and, therefore, identifying named entities is particularly hard. An extremely interesting example in rāmāyaṇa is janaka (जनक), which means “father” in general, but is also the name of a prominent character. Fourth, synonyms are often used to refer to the same person. In many cases, higher-order grammar rules are required to parse the meaning of a word and understand that it is a synonym. For example, it is not mentioned anywhere in the rāmāyaṇa text that daśarathī is the son of daśaratha and, hence, synonymous to rāma. However, samskṛta grammar rules make it obvious to someone who understands the language. Unfortunately, automatic language processing tools are incapable of using such higher-order rules at present.

Nair and Kulkarni (2010) have proposed a model for extracting implicit knowledge from amarakośa and storing it in a structured manner, and have constructed a tool for answering queries using this knowledge. Kulkarni et al. (2010) have built a Sanskrit WordNet\(^8\) by expanding the

Hindi WordNet. A production grammar for human relationships in sanskrita was proposed in Bhargava and Lambek (1992). It works for solitary words and cannot be directly used for text. Automatic translation tools, if available, can also be used where the entire text is translated to English and the KG is built from the translated text. However, we could not find any such tools. Although Sanskrit-English dictionaries\(^9\) provide a word-level translation of selected words from sanskrita to English, word-level translation often does not produce meaningful or grammatically correct text. We, thus, decided to use only the text as available in sanskrita. In future, we will explore the use of such tools and methods.

The rest of the paper is organized as follows. In Section 2, we explain the generic framework of the question-answering system. There exist some excellent tools for sanskrita that aid us in the analysis. For other cases, we build our own heuristic rule-based systems. In Section 3, we describe the automatic construction of the knowledge graph while the details of the various modules of the system are described in Section 4. Since bhāvaprakāśa nighaṇṭu is a technical text, we highlight its specialized processing in Section 5. In Section 6, we analyse the results of our experiments. Finally, in Section 7, we discuss the lessons learnt and future directions.

2 Proposed Framework

2.1 Knowledge Graphs (KG)

Knowledge graphs (KG) model real-world entities as nodes. Relationships among the entities are modelled as (directed) edges. For example, in a KG about human relationships in mahābhārata, arjuna and abhimanyu are nodes. They are connected by a directed edge from arjuna to abhimanyu labelled by the relationship “has-son” (putra).

In English, there have been several efforts in automated KG construction, notable among them being YAGO, DBpedia, Freebase, etc. Suchanek et al. (2007) built the YAGO ontology by crawling the Wikipedia and uniting it with WordNet using a combination of both rule-based as well as heuristic methods. Auer et al. (2007) built DBpedia that extracts knowledge present in a structured form on Wikipedia by template detection using pattern matching coupled with post-processing for quality improvement. Bollacker et al. (2008) designed Freebase, a database of tuples that is created, edited and maintained in a collaborative manner. Unfortunately, however, none of the above techniques are applicable for automatically building knowledge graphs in sanskrita.

Processing of text for YAGO depends on many IR/NLP tools that are available only in English and a handful of other languages, mostly European. The state of the art of these tools in sanskrita is still not standardized and may not be directly useful. Sanskrit Wikipedia\(^10\) also is not as resourceful as its counterpart in English. Hence, the amount of structured information available there is minuscule compared to the vast sanskrita literature that is developed over several millennia. Thus, a system such as DBpedia is not possible. A collaborative effort such as Freebase is also ruled out due to a paucity of active sanskrita users adept in digital technologies. To the best of our knowledge, there is no work that directly builds a knowledge graph from sanskrita texts.

2.2 Triplets

A common way of encoding the relationship information is in the form of semantic triplets. A triplet has the structure [subject, predicate, object] which indicates that the entity subject has the relationship predicate with the entity object. Hence, the fact that arjuna has a son abhimanyu is encoded as the triplet [arjuna, has-son (putra), abhimanyu] ([अजुर्न, पुत्र, अिभमन्यु]).

The KG is built automatically by extracting such triplets from the text. We target KGs on specific types of relationships, namely, human relationships for epics, and synonymous relation-
ships in nighaṇṭu. One of the foremost jobs, therefore, is to identify the relationship words. This is a corpus-independent set and depends only on the language. However, since the text is free-flowing (except in technical texts where there is a structure) and almost always written in poetry in the form of śloka, even when a relationship word is identified, the subject and object words may be anywhere around it (both before and after). śloka (श्लोक) is a semantic unit in saṃskṛta and is equivalent to a verse. Sometimes, one or both of these entities may not be even in the same śloka. Hence, a context window around the relationship word must be defined and searched for the relevant entities. Specifying the length of such a context window is not easy; if it is too short, relationships may be missed, while if it is too long, too many spurious relationships may be inferred. Even identifying the śloka boundaries may not always be trivial. Fortunately, however, these boundaries are clearly marked in the texts that we have worked on.

The details of how such triplets are extracted are explained in Section 3. The knowledge graph is maintained in an RDF format as a set of all such extracted triplets.

2.3 Questions

The next important task in the pipeline is to parse the natural language question. Since the question is also in saṃskṛta, we adopt similar processing as the text to extract triplets. In this work, we assume only factoid based questions such as “Who is the son of arjuna?” (अर्जुननाथ पुत्रः कः?) The triplet extracted from the above question will be [arjuna, has-son, X] ([अर्जुन, पुत्र, किम्]).

Since saṃskṛta is quite free with word ordering, the above question may be asked in different manners, such as अर्जुननाथ पुत्रः कः or कः अर्जुननाथ पुत्रः or अर्जुननाथ कः पुत्रः? All of these should yield the same triplet [अर्जुन, पुत्र, किम्].

The inverse question may also be asked: “Who is the father of abhimanyu?” (कः अभिमन्यूः पिता?) The above can be answered only if it is known that the inverse of “has-father” is the relationship “has-son”. This, again, is a property of the language and must be explicitly mentioned.

Hence, we maintain a map of such inverse relationship rules. Note that it is not always one-to-one. For example, “has-mother” is also the inverse of “has-son”, and “has-father” is the inverse of “has-daughter” as well. Gender information, therefore, becomes important.

We augment the initially built knowledge graph by adding appropriate inverse relationship edges. It is ensured that an inferred inverse relationship does not contradict a directly inferred relationship from the text. The details are in Section 3.4.

Even though the questions are simple and short, they may contain multiple triplets. For example, a question पाण्डुः पपनीः अत्राता कः? may be asked by someone who does not know what the relation brother-of-wife is called in saṃskṛta. This question contains two relationships, पपनी and अत्राता. The triplet form of these relationships would be [पाण्डु, पपनी, किम्] corresponding to the subquestion ‘Who was the wife of pāṇḍu?’ and [पपनी, अत्राता, किम्] corresponding to the subquestion ‘Who was the brother of wife (of pāṇḍu)?’. All of these must be extracted correctly.

Further, they must be linked properly. In the example above, we must ensure that the object of the first triplet is the subject of the second triplet, that is, the correct triplets are [पाण्डु, पपनी, X] and [X, अत्राता, किम्]. Here, a variable is used to denote the person that satisfies both the triplets.

Once these are correctly linked, a SPARQL query pattern is formed. The SPARQL query equivalent for the above question is

```sparql
SELECT ?A
WHERE {
  :पाण्डु :पपनी ?X .
  ?X :अत्राता ?A .
}
```

This is finally directly queried against the KG, and the answer is returned. Section 4 describes in detail the intricacies of the different steps of the question-answering system.

Figure 1 describes the overall framework. The final accuracy of the system is dependent on each of the modules of the architecture. For example, if the extracting triplets component is
Figure 1: Overall framework of the system.

very erroneous, then neither the KG information is captured correctly, nor is the intention of the question understood. The overall error is a cascading effect of the errors in each of the individual components. Thus, for a successful system, each component must be reasonably accurate.

3 Construction of Knowledge Graph

In this section, we describe in detail the automated construction of knowledge graph (KG). The input consists of saṃskṛta text (in digital Unicode format) of an entire work (such as mahābhārata, bhāvaprakāśa nighantu, etc.) and the type of relationships intended (e.g., human relationships, synonymous words, etc.). The output is a set of triplets in the form [subject, predicate, object] where the predicate is of the relationship type intended and subject and object are entities. If [a, R, b] is an output triplet, then it implies that object b is relation R of subject a.

3.1 Pre-Processing of Text

saṃskṛta is a morphologically rich language. A single word root, called prātipadika (प्रातिपदिक), can yield many forms depending on the case, gender and number. Similarly, a single verb root, called dhātu (धातु), can lead to many forms as well depending on the tense, person and number. In addition, various prefixes (upasarga, उपसर्ग) and suffixes (pratyaya, प्रत्यय) get affixed to these forms to generate thousands of other forms.

Further, words are very often joined together to form compound words using either pronunciation rules through a process called sandhi (संधि) or semantic rules through a process called samāsa (समास). Often, both are invoked together, and a series of words are joined together to form one big compound word.

Splitting these compound words into their base words is a highly complicated procedure and may not always be unambiguous. For this step, we make use of the Sanskrit Sandhi and
Compound Splitter, a tool\textsuperscript{11} by Hellwig and Nehrdich (2018). For example, if the input text is कणर्जुनयोः को श्रेष्ठः, the output is कणर्जुनयोः को श्रेष्ठः.

The next task is to semantically analyze the form of the word. Again, we use a third-party analyser tool, The Sanskrit Reader Companion\textsuperscript{12} from The Sanskrit Heritage Platform by Goyal et al. (2012). This tool outputs the case (vibhakti, विभक्ति), number (vacana, वचन) and gender (linga, लिङ्ग) for each word. The tool uses various abbreviations\textsuperscript{13} to convey the linguistic information.

For the running example, the analysis yields कणर् ['voc.', 'sg.', 'm.'], अजुर्न ['loc.', 'du.', 'm.'], किम ['nom.', 'sg.', 'm.'], श्रेष्ठ ['nom.', 'sg.', 'm.'].

Here, 'nom.', 'loc.' and 'voc.' are abbreviations used to denote nominative case (प्रथमा), locative case (समस्ती) and vocative case (समवचन) respectively. Similarly, 'sg.' and 'du.' indicate singular and dual number (एकवचन and द्विवचन). While 'm.' denotes the masculine gender (पुंलिङ्ग).

The word श्रेष्ठ gets correctly analysed: it is in the nominative case, is in singular number, and masculine gender. However, the other words require some more adjustments. For example, the word अजुर्न is shown to be in dual number. This is output since the original compound word consisted of two persons. However, now that they are separated, it should no longer be in dual number, but adjusted to be in singular number. Similarly, the case analysis for कणर् is wrongly output to be vocative. The reason for this again is the fact that the original structure of the compound word was lost. We adjust the case of previous words in a compound word by adopting the case of the last word in the compound word. Thus, the case for कणर् is changed to locative, since that is the case for अजुर्न.

3.2 Identifying Relationship Words

Given a particular relationship type, the set of words pertaining to it is corpus-independent and is a property of the language. For example, if human relationships are targeted, in संस्कृत, the (roots of the) relevant words are पितृ (father, पितृ), मातृ (mother, मातृ), पुत्र (son, पुत्र), पुत्री (daughter, पुत्री), पति (husband, पति), पत्नी (wife, पत्नी), etc. Of course, these words can appear in various forms. More importantly, their synonyms can also appear. For example, all the words दूरिः, तनया, आँध्राः mean पुत्री.

While these can be learned, since the set is mostly fixed, we have employed a key-value based approach where we have listed many of such relationship words along with their synonyms. For each such group of synonyms, there is a canonical word (e.g., पुत्री for the group of words indicating daughter) that is used in the KG. The identification of a relationship word is simply a match from this entire set of words.

3.3 Identification of Triplets

Once a relationship word is identified, it forms the predicate of a triplet. The next task, therefore, is to identify the subject and object corresponding to it.

It is expected that the subject and object entities will not be too far off from the predicate word. To bound the sphere of influence or context, we use śloka (श्लोक) boundaries. Each śloka considered as a semantic unit and is akin to a verse. Fortunately, for the texts we have used, the śloka boundaries are clearly marked. In this work, we restrict the context to be one śloka before and after the one where the predicate is found, i.e., a total of 3 śloka.

Since subjects and objects are entities, they generally occur as nouns in a language. The analyser tool (The Sanskrit Reader Companion) described earlier marks the parts-of-speech tags

\textsuperscript{11}https://github.com/OliverHellwig/sanskrit/tree/master/papers/2018emnlp
\textsuperscript{12}https://sanskrit.inria.fr/DICO/reader.fr.html
\textsuperscript{13}All the abbreviations used by the tool are listed at https://sanskrit.inria.fr/abrevs.pdf.
of words. It, however, does not distinguish between nouns, pronouns and adjectives. Since
there is a fixed set of pronouns for sanskṛta, we use that set to correct some of the nouns.
We, however, fail to distinguish the adjectives from the nouns in a satisfactory and consistent
manner. This is a major future work.

Within the nouns (and adjectives), we look for those that are in the genitive case (षठी िवभित). The
genitive case pertains to the saṣṭhī vibhakti (genitive case) and denotes sambandha (समन्न). The word sambandha in sanskṛta literally means relationship and, therefore, a noun exhibiting
the genitive case is the most likely candidate for a subject. For example, the अजुर्नय पुतः अभिमन्युः
means abhimanyu was son of arjuna. Here, ‘of arjuna’ is expressed by the genitive case of
the word (अजुर्न), i.e., अजुर्नय. Hence, all such nouns in the genitive case are marked as subjects.

The relationship word or the predicate can be in different cases, numbers and gender, though.
Since the object follows the predicate, according to sanskṛta grammar, it must be in the same
case, number and gender as the predicate. We use this rule to extract objects. To be precise,
an object is a noun that exhibits the same case, number and gender as the predicate word. In
the sentence अजुर्नय पुतः अभिमन्युः आसीत् word पुतः is the predicate word and the word अभिमन्युः is
the object and both of these words are in the nominative case (प्रथमा िवभित).

We insert all such extracted triplets in the KG. We assume that if an entity appears multiple
times, it refers to the same person. The above assumption is almost always correct barring some
exceptional cases.

3.4 Enhancement of Relationships

As explained earlier (in Section 2), just the base relationships may not always be enough to
answer a question. If the triplet [arjuna, has-son, abhimanyu] ([अजुर्न, पुतः, अभिमन्यु]) is stored,
the question “Who is the father of abhimanyu?” (कः अभिमन्योः िपता?) cannot be answered, even
though the information is present.

To be able to answer such queries, we have enhanced the KG with inverse relationships. For
example, the inverse of “has-father” is “has-son”. This, again, is a property of the language and
are explicitly stored.

As discussed earlier, the inverse relationships are not always one-to-one. For example, “has-
mother” is also the inverse of “has-son”, and “has-father” is the inverse of “has-daughter” as
well. Hence, we use the gender information of the subject and the object to disambiguate.

The complication does not end here. Imagine a question “Who is maternal uncle of Nakula?”
(नकुलमातुलः कः). This information may not be directly stored in the KG. The relationship मातुल is a composition of मातृ and भातृ. These components [नकुल, मातृ, मादी] and [मादी, भातृ, शय] may be present in the KG. Again, the situation is that the KG contains the information but
cannot answer the question.

To solve this, derived relations could be broken into their component base parts. Thus,
“has-maternal uncle” is stored as “has-mother” and “has-brother” with an additional (possibly
unnamed) node in between. In particular, from the triplet [नकुल, मातृ, शय], two more triplets
[नकुल, मातृ, X] and [X, भातृ, शय] could be generated. If there is already such a node X, it could
be used; otherwise, a new node could be created. However, addition of such dummy nodes has
not been explored in this work.

We achieve the same result by handling this issue at the time of querying. This is discussed
in Section 4.2. We maintain a list of relationships and their possible derivations from base
relationships. Once more this mapping is rarely one-to-one. For example, “brother-of” can be
composed of “son-of-father” and “son-of-mother”. Also, the gender must be taken care of.

A particularly interesting case is “has-ancestor” and “has-descendant”. These are recursive
relationships, and the depth of recursion can be anything, i.e., a ‘father’ is an ancestor, so is an
‘ancestor-of-father’, and so on. We do not handle these cases in the current work.

14karna was the son of kunti, and one of the kaurava was also named karna.
4 Question-Answering

We now describe one application, that of question-answering. We assume that the questions are asked directly in Sanskrit and are about factoids, i.e., about a single piece of information. We also assume that the questions are only about the relationships that the knowledge graph encodes. If not, the question is ignored, since clearly the KG is incapable of answering it. Further, the questions are assumed to be short and consist of a single sentence only.

The question is first pre-processed in the same manner as the text (Section 3.1). To be more precise, compound words are split using Sanskrit Sandhi and Compound Splitter a tool by Hellwig and Nehrdich (2018), the component words are analysed using The Sanskrit Reader Companion from The Sanskrit Heritage Site, and relationship words and nouns are identified. Next, triplets are extracted.

4.1 Identifying Triplets

A blank triplet is initialized. The question words are scanned one by one. For each word, it is determined if it can be a subject word, a predicate word or an object word. If the word is a noun in genitive case but is not a relationship word, then it is likely to be a subject word. The relationship words directly give the predicates. The object word is generally in the nominative case. For example, consider the question अजुर्न् य पुत्रः कः? (“Who is the son of arjuna?”). Since अजुर्न् is in genitive case, it is the subject. The word पुत्र is the predicate. The object is किम. The triplet formed, therefore, is [अजुर्न्, पुत्र, किम].

Once a triplet is filled up, another new triplet is initialized. This is necessary since there may be chain questions of the form अजुर्न् य पुत्रः कः? The triplets generated from this are [अजुर्न्, पुत्र, X] and [X, पुत्र, किम].

The process goes on till all the words in the question are processed.

At the end of this phase, the triplets thus formed are called query triplets.

4.2 Enhancing Triplets

Each query triplet is next enhanced to a set of triplets, called the enhanced triplet set. The rules for enhancing the relationship of a query triplet is the same as that used in processing the KG triplets. In particular, each complex relation is broken into its constituent parts and new triplets are created using the aforementioned mapping of relationships to its constituents.

Suppose, a predicate (i.e., relation) R can be decomposed to two base predicates R1 and R2. Then, if a query triplet is of the form [A, R, B], then two triplets of the form [A, R1, X] and [X, R2, B] are generated. Note that {[A, R, B]} and {[A, R1, X], [X, R2, B]} are equivalent expressions and either of them can return the correct answer from the KG. However, since it is not known which information is stored in the KG, both are used.

Thus, each query triplet QT is replaced by its enhanced triplet set ET = {QT} ∪ IT where IT is a set of triplets inferred from QT, as shown in the example below.

For the question अजुर्न् य मातुल्य पिता कः?, we first obtain the triplets {[अजुर्न्, मातुल्, X], [X, पितु, किम]}. These triplets are then enhanced by appropriately splitting the relationship मातुल्य using the rule मातुल्य = मातृ + भातृ. Here, QT = [अजुर्न्, मातुल्, X] and IT = {[अजुर्न्, मातृ, Y], [Y, भातृ, X]}. As a result, we get two triplet sequences for this question, {[अजुर्न्, मातृ, Y], [Y, भातृ, X], [X, पितु, किम]} and {[अजुर्न्, मातुल्, X], [X, पितु, किम]}.

4.3 Query Pattern

If the question contains only one query triplet, then members of its enhanced triplet set form the alternate query patterns. Suppose, however, the question contains n query triplets with their corresponding n enhanced triplet sets ET1, ET2, · · · , ETn. The Cartesian product of the elements of these sets form the alternate query patterns. Thus, if there are 2 enhanced sets with 2 and 3 elements in them, the total number of alternate query patterns is 2 × 3 = 6.
Each of these alternate query patterns are posed to the KG and answer triplets are returned. The correct field of the answer triplet is returned as the factoid answer.

We have not encountered a case where alternate query patterns return different answers. If, however, such a situation arises, a further disambiguation step (possibly using majority voting, etc.) is required.

5 Technical Texts

We have chosen a technical text bhāvaprakāśa which is one of the important texts from āyurveda. bhāvaprakāśa nighaṇṭu is a glossary chapter from this text, which contains detailed information about the medicinal properties of various plants, animals and minerals written in a śloka format. There are 23 adhyāya in this chapter. Being a technical text, bhāvaprakāśa nighaṇṭu has more structure than rāmāyaṇa or mahābhārata.

5.1 Structure

The text bhāvaprakāśa nighaṇṭu loosely adheres to the following structure.

- Substances (dravya, द्रव्य) with similar properties or from the same class occur in the same chapter. For example, all the flowers are in one chapter, all the metals are in another chapter.

- Each chapter consists of various blocks (sets of consecutive śloka), where each block speaks about one substance.

- Each block generally has the following internal components:
  - Synonyms of the concerned substance
  - Where that substance can be found
  - Properties of the substance. e.g., colour, smell, texture, composition and other medicinal properties
  - Differences between the different varieties of the substance

While the blocks are structured to some extent, the following deviations exist.

- The length of each block is not fixed.
- The number of synonyms of each substance are not fixed.
- The order of the components of the block varies from substance to substance to a certain extent.
- Some of the internal components may, at times, be absent such as the varieties of a substance.

Importantly, the separation between two consecutive blocks is not marked in the text. These points of deviation from the pattern act as hurdles in the process of understanding and exploiting the structure of a text to extract information. Understanding the structure of a text can be a challenging task. We have taken the help of domain experts15 to form our understanding of the structure described above.

Properties (guna, गुण) are of the form (name, value). A property value can be directly attached to a substance, or it can be attached through a property-name. For example, a substance is “red”, or, a substance has colour “red”.

Relationships of interest can be of a number of types. Some of them are: (substance-1, is-synonym-of, substance-2), (substance, property-name, property-value), (substance,
Table 1 lists the top-10 most frequent words and nouns along with their frequencies. Notice that most frequent words also contain stopwords like च, तद्, etc., while the list of nouns indicates that the standard property words such as वात, कफ, कुठ have a high frequency. Following this empirical evidence, we choose the top-50 most frequent nouns as “properties”. The substances are chosen from the rest of the nouns.

Table 1: Top-10 most frequent words, nouns and their frequencies from bhāvaprakāśa nighaṇṭu.

When a property is directly attached to a substance, we assume the relationship to be has-property.

\begin{itemize}
\item We have currently focused our efforts on a single relationship in the bhāvaprakāśa nighaṇṭu, namely, is-synonym-of. In other words, the triplets that we are interested in are of the form (substance-1, is-synonym-of, substance-2). Since the predicate is same for all triplets, we choose to get rid of it and think of the problem as simply finding pairs of synonyms.
\item This task is subdivided into two tasks, (1) finding śloka that contain the synonyms, and (2) given such a śloka, finding pairs of synonyms from it.
\end{itemize}

5.2 Property Words

The corpus is initially pre-processed in a similar manner as described in Section 3.1. However, a next layer of processing is done to extract more information.

The set of properties is a relatively small set of words. The names and values of these properties together are called property words. Since the property words recur heavily in every block that describes a substance, they are expected to have much higher frequencies than the names of substances. We test this hypothesis by performing a frequency analysis of the top words and nouns in the entire text.

Table 1 lists the top-10 most frequent words and nouns along with their frequencies. Notice that most frequent words also contain stopwords like च, तद्, etc., while the list of nouns indicates that the standard property words such as वात, कफ, कुठ have a high frequency. Following this empirical evidence, we choose the top-50 most frequent nouns as “properties”. The substances are chosen from the rest of the nouns.

Table 2: Features of a śloka.

| Counts | Words, Nouns, Properties, Non-Properties, Special Words, Pronouns, Verbs, Case-i Nouns \(i = 1, \ldots, 8\), Number-j Nouns \(j = \text{singular, dual, plural}\).

Table 2: Features of a śloka.
5.3 Synonym śloka Identification

Generally, the different synonyms of a substance are listed in a single śloka at the beginning of a block. A set \( \{ n_1, n_2, \ldots, n_k \} \) of nouns is called a synonym-group if every \( n_i \) is a synonym of every other \( n_j \). Any such \((n_i, n_j)\) pair is called a synonym-pair. A śloka that gives information about a synonym-group or synonym-pairs is referred to as a synonym śloka. The first task is to identify instances of such synonym śloka.

To identify a synonym śloka automatically, we use various linguistic features of a śloka and then use them in a classifier. We create a 42-dimensional feature vector per śloka. The features are based on counts and their ratios. Some of the notable features include number of nouns, pronouns and verbs, number of property words present in a śloka, ratios of property words to total number of words, number of words in each case (वचन), and so on. The category “specials” contains adverbs, conjunctions and prepositions.

Once each śloka is converted into a 42-dimensional feature vector, various classifiers and ensemble methods are used to classify into a synonym śloka or otherwise.

5.4 Identifying Synonymous Nouns

Once a synonym śloka is identified, the next task is to identify the synonyms from it. Given a synonym śloka, we first exclude all the property words from it. We next consider the list of all the nouns in the śloka: \( \{ n_1, n_2, \ldots, n_k \} \).

We call a pair of nouns \((n_i, n_j)\) a synonym pair if both \( n_i \) and \( n_j \) have the same case (वचन) as well as the same number (वचन). We do not use the gender (िलग) information since there are examples of synonymous substance names that belong to different genders. For example, चन्य (neuter), चन्यका (feminine) and ऊषणा (feminine) form a synonym group.

6 Experiments and Results

In this section, we present our experiments and discuss the results. The code is written in Python3. All experiments are done on Intel(R) Core(TM) i7-4770 CPU @ 3.40GHz system with 16 GB RAM running Ubuntu 16.04.6 OS. RDF is used for storing the knowledge graph, and querying is done using SPARQL querying language. Python library RDFlib is used for working with RDF and SPARQL.

6.1 Datasets

We have worked with texts containing two types of relationships:

1. **Human Relationships:** The two well-known epics of ancient India, rāmāyaṇa and mahābhārata, contain numerous characters and relationships among them. We have, thus, used them as datasets for human relationships.

2. **Synonymous Relationships of Substances:** āyurveda, the traditional Indian system of medicine, has a rich source of information about medicinal plants and substances. We considered bhāvaprakāśa nighaṇṭu, a glossary chapter of the āyurveda text bhāvaprakāśa as the dataset. It enlists numerous medicinal plants and substances along with their properties and inter-relationships. In this work, we only consider the relationship “is-synonym-of”.

Table 3 shows the statistics about the datasets considered.

6.2 Knowledge Graph from rāmāyaṇa and mahābhārata

Table 4 shows the various statistics about the knowledge graphs constructed from the datasets rāmāyaṇa and mahābhārata.

While pre-processing the text requires a large amount of time, the other steps are significantly faster. The querying times are in microseconds.
| Dataset                      | rāmāyaṇa | mahābhārata | bhāvaprakāśa nighaṇṭu |
|-----------------------------|----------|-------------|------------------------|
| Type                        | Classical| Classical   | Technical              |
| Chapters                    | 7 (kāṇḍa)| 18 (parvan) | 23 (adhyāya)           |
| Documents                   | 606      | 2,327       | 23                     |
| śloka                       | 23,934   | 81,603      | 4,244                  |
| Words (total)               | 2,69,603 | 17,49,709   | 31,532                 |
| Words (unique)              | 1,52,878 | 6,36,781    | 19,689                 |
| Nouns (total)               | 9,553    | 20,545      | 3,684                  |
| Nouns (unique)              |          |             |                        |

Table 3: Statistics of the various datasets used.

|                      | rāmāyaṇa | mahābhārata |
|----------------------|----------|-------------|
| Time taken           |          |             |
| Preprocessing        | ~ 3.5 days | ~ 13 days |
| Triplet Extraction   | 14.18 sec | 57.19 sec  |
| Triplet Enhancement  | 0.40 sec  | 2.05 sec   |
| Before enhancement   |          |             |
| Entities (Nodes)     | 1,711    | 3,552       |
| Triplets (Edges)     | 6,155    | 18,936      |
| Type of Relations    | 24       | 25          |
| After enhancement    |          |             |
| Entities (Nodes)     | 1,711    | 3,552       |
| Triplets (Edges)     | 16,367   | 48,395      |
| Type of Relations    | 27       | 27          |

Table 4: Statistics of the knowledge graphs for the human relationships.

6.2.1 Questions

To evaluate the performance of the question-answering system, we collected 35 questions from rāmāyaṇa and 45 questions from mahābhārata from 12 different users, with each user contributing between 5-10 questions.

6.2.2 Performance

We evaluate the performance of the system for three tasks.

- **QParse** refers to the query parsing task. If the query pattern is correctly formed from the natural language question, we count it as a success; otherwise, it is a failure.

- **QCond** is the conditional question answering task subject to correct query formation. A success is counted only if the answer to the question is completely correct.

- **QAll** is the overall question answering task.

Table 5 demonstrates the performance of our system on the collected questions. The query parsing task is fairly accurate. However, the accuracy of question-answering has a lot of scope for improvement. We next analyze some of the reasons for failure.

6.3 Analysis of Wrong Answers

We analyze the wrong answers in two phases: parsing errors and answering errors.
| Text       | Task   | Total | Found | Correct | Precision | Recall | F1   |
|------------|--------|-------|-------|---------|-----------|--------|------|
| rāmāyana   | QParse | 35    | 33    | 27      | 0.82      | 0.77   | 0.79 |
|            | QCond  | 27    | 19    | 09      | 0.47      | 0.33   | 0.39 |
|            | QAll   | 35    | 20    | 10      | 0.50      | 0.29   | 0.37 |
| mahābhārata| QParse | 45    | 45    | 41      | 0.91      | 0.91   | 0.91 |
|            | QCond  | 41    | 36    | 22      | 0.61      | 0.54   | 0.57 |
|            | QAll   | 45    | 40    | 23      | 0.58      | 0.51   | 0.54 |
| Combined   | QParse | 80    | 78    | 68      | 0.87      | 0.85   | 0.86 |
|            | QCond  | 60    | 55    | 31      | 0.56      | 0.46   | 0.50 |
|            | QAll   | 80    | 60    | 33      | 0.55      | 0.41   | 0.47 |

Table 5: Performance of the question-answering tasks.

6.3.1 Parsing Errors

Following are some examples of queries that got incorrectly parsed.

- **गाधारी: पुताणाम ्नामािन कािन → [गाधारी, पुत, िकम्]**
The question expects all the names of sons of gāndhārī गाधारी but the parsed query only asks for the name of ‘a son’ of gāndhārī गाधारी. This error originates from the fact that we have not considered the number (वचन) of the relationship word while parsing the question. Strictly speaking, however, the question is not a simple factoid question. Nevertheless, number (वचन) can be considered, and all triplets that satisfy the criteria can be returned.

- **कणार्जुनयोः कः सबधः → [िकम ्, िकम्, सबध]**
There are patterns in the question set that are not handled by our algorithm. For example, the algorithm did not handle the way of asking the relationship between two people using the word सबध and, thus, results in a triplet that does not make sense. If the same question was phrased as कणां अजुर्नय कः, अजुर्नय कणां कः, अजुर्नय कणां कः and कणां कः अजुर्नय also get parsed correctly to [अजुर्न, किम, कणा].

- **विवाहः अजुर्नय अभवत्कया सह → [अजुर्न, किम, विवाह]**
The question parsing algorithm, while tolerant to some extent, is not fully robust to free word order. An occurrence of विवाह word needs to be followed by the instrumental case (तृतीया) word, followed by सह for it to be parsed correctly. Thus, if the question is changed to अजुर्नय विवाहः कया सह अभवत्, it will get parsed correctly to yield [अजुर्न, पनो, किम].

6.3.2 Answering Errors

Out of the queries that correctly get parsed, following are the queries which we cannot find the answer due to the inability of performing path queries.

- **उमिला द्वारकसय का → [द्वारक, किम, उमिला]**
This question would have got answered only if there is a direct edge between द्वारक and उमिला. If there is no direct edge, but an edge between द्वारक and उमिला exists along with the edge between उमिला and उमिला, then this answer should have been found. Our inability to pose it as a graph path searching query is the cause of this failure.

- **हनुमत: पिता क: → [हनुमत, पितृ, किम]**
We correctly parse this question and there exists a triplet [भासुत, पितृ, पवन]. However, as the information that भासुत is another name of हनुमत is not present in the knowledge graph, resulting in the failure to answer this question.
6.3.3 Correct Answers despite Wrong Parsing

Interestingly, there are cases when despite the query being parsed incorrectly, the correct answer exists in the result set. The following examples highlight two such cases.

- रावणः किनःतमः भाता कः → [रावण, भातृ, किनः]
  The triplet is incorrectly formed, since we did not capture the information किनःतमः (youngest). However, the correct answer, िवभीषण, being a brother of रावण, is captured in the result set. The question is, thus, deemed to be answered correctly.

- भीमः अगःजः कः आसीत् → [भीम, भातृ, अगःजः]
  Similar to the previous question, we classify the formed triplet as incorrect, for missing the quality ‘elder’. However, answers found do contain the correct answers युिधिठर and कणर्.

6.4 Analysis of Errors in KG Triplets

We now take a look at in-depth analysis of some incorrect triplets retrieved by our method and investigate the reasons behind the failure. For this purpose, we consider a small extract from the corpus and follow the entire pipeline of forming the triplets.

Table 6 gives an extract containing three śloka (25, 26 and 27) from adhyāya 67 of the ādi parvan in mahābhārata. Table 7, Table 8 and Table 9 contain the detailed analysis of these śloka as well as a classification of the errors in the analysis.

6.4.1 Types of Errors

We now discuss the possible errors, as exemplified in the analysis tables 7, 8 and 9.

- AnalysisError:
  This is an error in the analysis obtained from The Sanskrit Heritage Parser. For example, the word भायार् in śloka 25 is analysed as a form of भािर instead of a form of भायार्. Thus, the prātipadika identified is wrong. This also results in the other analysis details such as case, gender and number, being wrong. It should be noted that words can be analyzed differently in different contexts. For example, the word भायार्, if analyzed standalone as a word, can get analyzed correctly; however, in the current context, it results in an erroneous analysis.\(^\text{16}\)

- OversplitError:
  This is an error in the sandhi and samāsa splitter, where a word that should not have been split is split. For example, in śloka 26, वर्ेह्रिः is wrongly oversplit as वर् and ख्रिः, and ब्रह्मवादिनी
as ब्रह्म and वादिन्. Sometimes a word is erroneously oversplit by the analyser as well. Again, in śloka 26, for example, वादिन् is erroneously split as वा and आदिन.

- **SandhiSamaasaError:**
  There can be error in analyzing the correct sandhi and samāsa in a word. In other words, when a word is broken, the constituent words can be erroneous. For example, in śloka 27, योगिस्वैधा जगत् is split as योग, िस्वैधाः and जगत्, where योगिस्वैधा, in addition to being oversplit, is also changed into plural form.

### 6.4.2 Extracting Triplets

After obtaining the analysis, when we proceed to extract triplets as mentioned, we tried using 4 different filters for extracting triplets. In every filter, the case of the subject word must be sixth (षठी) and the gender of the object word must match with the gender of the predicate word. Filters differ in the allowed positions of subject and object words relative to the predicate word as well whether the number (वचन) of the object is matched or not.

Table 10 describe the different filters. Filter 1 is the superset of other filters and Filter 2 is the superset of Filter 3 and Filter 4.

Through empirical evidence, we found that Filter 2, although being stricter than Filter 1, still captures roughly the same number of triplets while reducing the errors. Filter 3 and Filter 4, while exhibiting fewer mistakes, find fewer correct triplets as well. While we acknowledge that such an analysis is required on a larger scale to decide among the filters, for our purposes, we choose Filter 2 based on the empirical evidence, and proceed further.

### 6.4.3 Analysis of Incorrect Triplets

In this section, we take a look at some wrong triplets that were retrieved and the reasons behind their retrieval.

- (प्रत्येक, पुत्र, मनोविन्द)
  śloka 26, listed in Table 6 contains two relationship words, पुत्र and पुत्रौ. The first one is used in relation to देवल who is the son of प्रत्येक, and the triplet (प्रत्येक, पुत्र, देवल) is found correctly. However, because of the presence of the second word पुत्रौ, which is actually used with देवलस्य, a wrong triplet (प्रत्येक, पुत्र, मनोविन्द) is formed. Due to the same reason, (प्रत्येक, पुत्र, शामात) is also

---

| Word | Root | Analysis | Is-Noun | Is-Verb | Error |

Table 9: Analysis of śloka 27.

found. Since the context for finding relationships covers the full śloka, when a single śloka contain multiple relationships, such errors occur. If sentences were instead used, the error could have been reduced. However, there do not exist clear sentence boundaries.
| Filter | Position of subject | Position of object | Number (स्थन) of object |
|--------|---------------------|--------------------|------------------------|
| 1      | Either side of predicate | Either side of predicate | Does not matter |
| 2      | Either side of predicate | Either side of predicate | Must match predicate |
| 3      | Before predicate     | After predicate     | Must match predicate   |
| 4      | After predicate      | Before predicate    | Must match predicate   |

Table 10: Filters for extracting triplets.

| Scenario | Training Set          | Testing Set            |
|----------|----------------------|------------------------|
| S1       | First 20\% of adhyāya 1 | Rest 80\% of adhyāya 1 |
| S2       | First 20\% of adhyāya 2 | Rest 80\% of adhyāya 2 |
| S3       | adhyāya 1             | adhyāya 2              |
| S4       | adhyāya 2             | adhyāya 1              |

Table 11: Training and testing scenarios on bhāvaprakāśa nighaṇṭu.

- (वृहस्पति, भिगनी, शी)
  As discussed in Section 6.4.1, the word वर्षी gets oversplit wrongly into वर and शी, and the split words are analysed separately, resulting in the wrong triplet. Even if this split did not occur, we would have got वर्षी as the object in this triplet. This is wrong since this is actually an adjective used for the sister of वृहस्पति. Since we currently do not have any mechanism of distinguishing between nouns and adjectives, it would have resulted in incorrect triplets.

- (अिनल, पनी, िशवा)
  The relationship word that occurs in śloka 25 in Table 6 is भायार्, which suffers an AnalysisError and is identified as तृतीया of भािर instead of पना of भायार्. Due to the root word (प्रतिपक्त) itself being misidentified, it is not recognized as a relationship word and thus, does not satisfy the filtering criterion. Consequently, the triplet (अिनल, पनी, िशवा) is missed.

- (प्रभास, पनी, ब्रम्बादिदी)
  In śloka 27, भायां of प्रभास is referred to with a pronoun सा, which is connected to a noun in the previous śloka. To correctly identify the triplet (प्रभास, पनी, ब्रम्बादिदी), we would need a mechanism to connect pronouns to their proper subjects. We do not handle this currently.

6.5 Synonym Identification from bhāvaprakāśa nighaṇṭu

Questions for the bhāvaprakāśa are implicit, as we are considering only the synonymous relationship. Therefore, the evaluation is performed on the synonym groups and synonym pairs identification. We created ground truth for the first two adhyāya of bhāvaprakāśa nighaṇṭu. adhyāya 1 contains 261 śloka, while adhyāya 2 contains 131 śloka. For each of these śloka, we first identified if it is a synonym śloka. If it is so, we next extracted the list of synonymous words contained in it.

6.5.1 Classification

Using the feature vectors obtained for each śloka, we used various classifiers to classify each śloka as a synonym śloka or otherwise. We tried four practical scenarios of training and testing set choices as described in Table 11.
Table 12: Performance of classifiers in identifying synonym śloka.

| Scenario | Train Size | Test Size | P | P' | TP | Accuracy | Precision | Recall | F1 |
|----------|------------|-----------|---|----|----|----------|-----------|--------|----|
| S1       | 52         | 209       | 84 | 56 | 42 | 0.73     | 0.75      | 0.50   | 0.60|
| S2       | 26         | 105       | 44 | 43 | 31 | 0.76     | 0.72      | 0.71   | 0.71|
| S3       | 261        | 131       | 54 | 45 | 36 | 0.79     | 0.80      | 0.67   | 0.73|
| S4       | 131        | 261       | 90 | 99 | 66 | 0.78     | 0.67      | 0.73   | 0.70|

Table 13: Examples of errors in classification (scenario S3).

The size of training sets were chosen to be smaller than those of test sets to resemble the real-world scenario where the ground truth can be created for only a small portion of the text, and predictions are needed to be made on the rest.

Table 12 shows the performance of the best classifier under various scenarios in identifying the śloka containing synonyms.

Table 13 shows some examples of wrongly classified śloka for the best performing scenario S3.

6.5.2 Synonym Identification

We next evaluate the performance of finding synonymous pairs from a synonym śloka. Table 14 shows the performance in identifying groups of synonymous substances. We say that a group of substances is covered even if a single pair in the group is identified. The result shows that even this has a scope for improvement.

Table 15 shows an example of a synonym śloka where none of the pairs are extracted correctly. The correct synonyms are चन्द्रिका, चंद्रेण, पशुमेहनकारिका, नामदेव, कारवी, भद्र, वासपुष्प, सुवासरा. We find the pairs (चन्द्रिका, हनु), (चन्द्रिका, भद्र), (चन्द्रिका, सुपुष्प), (नामदेव, रचि), (नामदेव, हनु), (नामदेव, सुपुष्प), (सुपुष्प, हनु), none of which are correct. The reasons for the errors are shown in Table 16. Almost all the nouns are analysed incorrectly, resulting in the group being completely missed.

In addition to the errors discussed in Section 6.4.1, an additional error occurs here, that of TextError. This refers to an error in the text corpus that we are working with. In particular, the original śloka contains the word चन्द्रिका while the corpus we are working with, has that word split as चन्द्रिका and का, which results in this word not being analysed correctly. After correcting this error manually, we now obtain a valid pair (चन्द्रिका, भद्र), thus covering this group.

We next analyse the finer errors that occur when some members of a synonymous group are identified correctly, but not all. Table 17 shows the performance.

Table 18 shows a synonym śloka from adhyāya 1 (हरिकथाकथितम्).

This śloka contains a total of 11 synonyms. We find pairs of synonyms involving 9 out of

Table 14: Group coverage in synonym pair identification.
these, synonym pairs involving 8 of which are correct. We show examples of some of the false negatives and false positives among the pairs of synonyms identified.

- **False Positive:** (अमृता, अवी)
  The word अमृता is split wrongly as अवी and अथा, and are then analysed separately. This results in both अमृता and अवी being in the same case (प्रथमा) and same number (एकवचन), thus getting wrongly marked as a synonymous pair.

- **False Negative:** (अभया, अमृता)
  The word अभया gets analysed as instrumental (तृतीया) case of अभा instead of nominative (प्रथमा) case of अभया. This results in a case mismatch with अमृता and the pair is not extracted as a synonymous pair.

### 7 Conclusions and Future Work

In this paper, we have designed a framework to build a knowledge graph (KG) directly from सांस्कृत texts, and use it for question-answering in सांस्कृत. Our framework has multiple components and is based on rules and heuristics developed using the knowledge of grammar of सांस्कृत language and structure of the text.

However, for almost all the components, the accuracy can be improved. Improvements on any of these components by us or by others will make the system better. In future, we would like to work on improving the modules in a systematic manner. The biggest source of improvement can possibly come from a better word analyser. Usage of dictionaries, thesauri (such as अमराकोश) and Sanskrit WordNet will be explored to see if they can help in understanding the structure of a word better. Crowd sourcing tools as well as human experts can also help refine some of
Table 17: Performance of finding synonym pairs.

| Synonym śloka | P   | P'   | TP  | Precision | Recall | F1   |
|---------------|-----|------|-----|-----------|--------|------|
| adhyāya 1     | 231 | 90   | 534 | 562       | 369    | 0.66 | 0.69 | 0.67 |
| adhyāya 2     | 161 | 54   | 300 | 348       | 214    | 0.62 | 0.71 | 0.66 |

Table 18: Example of wrong pairs from adhyāya 1 of bhāvaprakāṣa nighaṇṭu.

| Synonym śloka | sandhi-samāsa split | P   | P'   | TP  |
|---------------|----------------------|-----|------|-----|
| हरितकयोः पर्याय कार्यस्य पुनामस्मिता | हरितकृ-अयः पर्या कार्यस्य पुनाम-अमुता | 11  | 9    | 8   |
| हैमवत्यायपि चेलकी शेत्यसी शिवाः | हैमवती-अवथा च-अपि चेलकी शेत्यसी शिवाः | ॥ ॥ | ॥ ॥ | ॥ ॥ |

Acknowledgements

We thank Dr. Sai Susarla, Dean at Maharshi Veda Vyas MIT School of Vedic Sciences, Pune, India, and his team, for sharing their expertise in āyurveda with us. We thank Shubhangi Agarwal and Rujuta Pimprikar for the help in creating ground truth as well as providing valuable feedback from time to time. We thank Dr. Kripabandhu Ghosh and Garima Gaur for the discussions and valuable feedback. We thank our samskṛta teacher Pralay Manna for enabling us in understanding the language better. We also thank the anonymous reviewers for their comments and suggestions.

the steps. We would also like to expand the question-answering framework to work with longer questions that are not necessarily of the type factoid.

To conclude, we hope that this effort serves as a step towards the ultimate aim of automatically building a full-fledged knowledge graph from a samskṛta corpus.
