Details of protocols for ancient DNA

Extractions of mammoth samples in Norfolk were carried out in a room dedicated to ancient DNA work in a CleanSpot PCR hood (Coy Laboratory) following an established protocol [1]. Approximately 0.5 gram of drilled bone powder was used per extraction. The room had never been previously used for molecular biological work. Separating rooms used for processing ancient DNA samples and performing modern molecular biological investigations is a useful way of minimizing contamination risk [2]. Amplified PCR products never entered the clean room nor did modern DNA. Extraction of DNA from the bone samples was done using GeneClean Ancient DNA Kits (MP Biomedicals) according to manufacturer’s instructions. Mock extractions were performed to control for contamination introduced during extraction.

PCR amplifications were performed at least twice per primer pair. PCR amplification was performed for 40 cycles using HiFi Supermix (Invitrogen) which is known to perform well on ancient DNA extracts [3]. Annealing temperatures were chosen based on the Tm of the primers. All PCR products were cloned into T overhang vectors, transformed into competent bacteria, with positives colonies identified by colony PCR using M13 forward and reverse primers and multiple clones per PCR product sequenced using T7 or SP6 primers (Functional Biosciences, Inc.). Direct sequencing can lead to an erroneous sequence due to contamination and DNA damage in the extract. Cloning and sub-sampling individual representative amplified sequences provides a better representation of the original template amplified [4], therefore none of the consensus sequences generated in this study were determined from direct sequencing.

All pre-amplification work in Thunder Bay was performed in a ‘Clean Lab’. Only ancient and degraded samples with low-copy number are allowed in the Clean Lab area. This lab is physically separated from post-amplification analysis, free from PCR product, slight positive pressure, surface sterilized weekly with a thorough monthly sterilization, and monitored quarterly to ensure the absence of modern DNA contamination. The outer surface of the container holding the tooth and bone were surface sterilized with 10% bleach, irradiated with UV light for 20 minutes, then passed
into a clean laboratory area. Preventative measures were taken to reduce the introduction of modern DNA to this area by wearing protective gear: a Tyvek™ suit (Kepler), hair net, face mask, an extra pair of Tyvek™ sleeves (Kepler), inner pair of nitrile gloves, outer pair of latex gloves, and safety glasses. In addition, once suited up, each analyst entered an air shower designed to remove any residual surface particulates from the external surface of the Tyvek™ suit before entering the Clean Lab.

The bone and tooth sample were surface sterilized with successive washes of 10% bleach, sterilized water, and 70% ethanol (Fisher). A Dremel™ tool was used with separate bits to cut a small portion of sample. These samples were separately milled into a fine powder using a Retsch mixer mill. Approximately 200 mg of powder was placed into 2.0 mL tubes. The extraction buffer was prepared using a modified protocol [5]: 1.5 mL of 0.5M EDTA (Sigma), 75 µL of 20% N-lauroylsarcosine (Sigma), and 40 µL of Proteinase K (Qiagen). A blank tube was also prepared containing extraction buffer only to act as a negative control. The tubes were placed onto an Eppendorf Thermomixer-R to incubate overnight at 56°C and 1000 rpm.

Next, the sample tubes were centrifuged for 5 minutes at 13,000 rpm and the aqueous extract transferred to a sterile 15 mL tube; 400 µL of phenol (Sigma) and 400 µL of chloroform:isoamyl alcohol (24:1, v/v) (Sigma) were added directly to each 15 mL tube. The tubes were vortexed for 1 minute then centrifuged for 5 minutes at maximum speed. The extract in each tube separated into two layers. The top layer was transferred with a pipette into a sterile 15 mL tube and the above process repeated with this layer. The bottom layer was discarded. After transferring the top layer to another sterile 15 mL tube for the second time, 800 µL of chloroform:isoamyl alcohol (24:1, v/v) was added. The tubes were vortexed for 1 minute then centrifuged for 5 minutes at maximum speed. The top layer was transferred to another sterile 15 mL tube. To each tube was added a 10% volume of 3M sodium acetate (Sigma) and 2.5 times the volume of cold anhydrous ethanol (Commercial Alcohols). These tubes were placed into a -20°C freezer overnight to allow precipitation of product. The next day, the tubes were centrifuged for 5 minutes at maximum speed. The supernatant was discarded. A volume of 1.5 mL of 95% ethanol (Commercial Alcohols) was added to each tube, the tubes vortexed to resuspend the precipitate and centrifuged for 10 minutes at maximum speed. The supernatant was
discarded and the precipitate allowed to dry for 1 hour. After this time the precipitate was resuspended in 100 µL TE buffer (10 mM Tris-HCl, pH 8.0, 10 mM EDTA) and purified additionally with Micro Bio-Spin 30 Chromatography Columns (Biorad).

The samples were amplified using Platinum® Taq DNA Polymerase (Invitrogen), 25 µL reaction: 2.5 µL 10X PCR buffer (minus Mg), 0.5 µL dNTP (0.25mM each, Invitrogen), 1.0 µL 50 mM MgCl2, 0.1µL Platinum® Taq DNA Polymerase (5U/µL), 0.5 µL primer mix (0.1 µM each), 0.5 µL 20 mg/mL BSA (Fermentas) on an Eppendorf Mastercycler™. A hot start of 94°C for 2 minutes was used followed by 50 cycles of 94°C for 30 seconds denaturation, 47-65°C for 1 minute annealing, and 72°C for 2 minutes extension. 5 µL of each PCR product was mixed with 3 µL of 6X dye and resolved using 6% polyacrylamide gel electrophoresis run at 118V for 45 minutes. Ultra low range (Fermentas) size ladder was run in tandem with the PCR products. The 6% PAGE gel was stained with 0.4 µg/mL ethidium bromide (Sigma) for visualization of successful DNA amplification. Successful PCR products were purified using the QIAquick PCR purification kit (Qiagen) as per manufacturer’s protocol. Colony PCR and sequencing were performed as in Norfolk.

**Indigirka mammoth mtDNA clade**

Recent genetic analysis of woolly mammoth populations suggests that there are two distinct mtDNA clades of mammoths with “Clade II” having become extinct much earlier than “Clade I” or the species as a whole. Whether Clade I and Clade II mammoths differ in phenotype is not clear. A 100 bp fragment of the mitochondrial DNA 16S rDNA was sequenced, which indicated that the Indigirka mammoth sample belonged to Clade I, the more common mtDNA clade of woolly mammoth [6].

**Jarkov mammoth, exon 2 results**

While the complete FGF5 coding sequence was obtained for an Indigirka mammoth, few FGF5 fragments could be retrieved from the Jarkov mammoth. All FGF5 fragments retrieved were identical in sequence between the Indigirka mammoth and the Jarkov mammoth, with the exception of exon 2 amplicons from the Jarkov mammoth, which may have been due to contamination. Exon 2 was amplified in two
fragments. The first fragment was identical between all elephants and mammoth samples sequenced and differed from human at two positions. A second exon 2 fragment in the Jarkov mammoth was identical to human but differed from the elephants and the Indigirka mammoth at two positions. It seems likely that the second amplified fragment from the Jarkov mammoth represents contamination rather than variation among mammoth sequences. The difficulty in distinguishing between the alternatives is that exon 2 only differs between elephantids and human at four positions. The controls were negative and the same sequence was obtained from the Jarkov mammoth in all clones of two independent PCR reactions. This does not exclude the possibility that human contamination of the sample itself yielded the result. However, the other amplifications were identical to the Indigirka mammoth suggesting that contamination with human DNA was not present (Additional Figure S2). In addition, primers used to amplify mammoth sequences were designed based on elephant sequences which are quite divergent at the DNA level from human and thus not expected to co-amplify. The Jarkov mammoth failed to yield products for the majority of the PCR reactions successful with the Indigirka mammoth. Thus, it remains unclear whether there is among mammoth diversity in the FGF5 gene. Given the complete sequencing from the Indigirka mammoth, and the limited success for the majority of the PCRs from the Jarkov mammoth, further analysis was restricted to the Indigirka sequence.

Table S2. Primer combinations used for PCR and sequencing of extant elephant DNA.
Additional figures S1-S4 – Elephant sequences are used to show the positions of the overlapping primer pairs used to generate the sequences from the woolly mammoth for FGF5.

The PCR primers are shaded in grey and the product generated for each fragment is shown as a line above the sequence with the primer combination shown. The alignment uses the top sequence as a reference. Dots indicate identity to the reference and changes are shown as the base change. The primer sequences and combinations used are shown below the sequence alignments. Figures are in this order: exon 1, exon 2, exon 3 and promoter.

F5 + R6
Additional figure S5 – Graphical depiction of FGF5 amino acid variation along the MAFFT alignment carried out with the G-INSi alignment algorithm with the JTT200 scoring matrix.

Composition shows the most frequent residue in each position. Heterogeneity shows the relative residue frequency at each site. Identity allows for a quick visual identification of variable sites. Heterozygosity represents the expected heterozygosity at each residue, i.e. the sum of the squared frequencies of each amino acid at a site. “Charges” indicates whether the most frequent residue at each position is acidic, basic, or uncharged. Hydrophobicity depicts the most frequent hydrophobic, hydrophilic, and charged residues at each position.
Additional figure S6 – FGF5 amino acid sequence maximum likelihood phylogram based on the G-INSi alignment algorithm with the JTT200 scoring matrix.

The opossum FGF5 amino acid sequence was used as outgroup. The scale bar denotes 0.05 substitutions/residue. $\alpha = 0.32417$. Log-likelihood = -2594.951392.
Additional figures S7-S10 – Clone sequences from which the mammoth *FGF5* sequences were derived are shown by these figures (each shown in one figure) in the following order: exon 1, 2 and 3 (x1, x2, x3) followed by the promoter. Sequences are provided as an alignment in FASTA format. Modern elephant sequences determined by this study are also shown. “Ind” stands for the Indigirka mammoth. PCRs of the same fragment cloned and sequenced multiple times are designated A, B, C etc. The clone number is shown next to the letter e.g. A.1, A.2.
