ON SOME COMPONENTS OF HILBERT SCHEMES OF CURVES

FLAMINIO FLAMINI, PAOLA SUPINO

Abstract. Let $I_{d,g,R}$ be the union of irreducible components of the Hilbert scheme whose general points parametrize smooth, irreducible, curves of degree $d$, genus $g$, which are non-degenerate in the projective space $\mathbb{P}^R$. Under some numerical assumptions on $d$, $g$ and $R$, we construct irreducible components of $I_{d,g,R}$ other than the so-called distinguished component, dominating the moduli space $\mathcal{M}_g$ of smooth genus-$g$ curves, which are generically smooth and turn out to be of dimension higher than the expected one. The general point of any such a component corresponds to a curve $X \subset \mathbb{P}^R$ which is a suitable ramified $m$-cover of an irrational curve $Y \subset \mathbb{P}^{R-1}$, $m \geq 2$, lying in a surface cone over $Y$. The paper extends some of the results in [12, 13].

Introduction

Projective varieties are distributed in families, obtained by suitably varying the coefficients of their defining equations. The study of these families and, in particular, of the properties of their parameter spaces is a central theme in Algebraic Geometry and sets on technical tools, like flatness, base change, etc., as well as on the existence (due to Grothendieck, with refinements by Mumford) of the so-called Hilbert scheme, a closed, projective scheme parametrizing closed projective subschemes with fixed numerical/projective invariants (i.e. the Hilbert polynomial), and having fundamental universal properties.

Hilbert schemes have interested several authors over the decades, owing also to deep connections with several other subjects in Algebraic Geometry (cf. e.g. bibliography in [39] for an overview). Indeed, results and techniques in the “projective domain” of the Hilbert schemes have frequently built bridges towards other topics in Algebraic Geometry, as by improving already known results, as by providing new ones. The interplay between Hilbert schemes of curves in projective spaces and the Brill–Noether theory of line bundles on curves is one of the milestones in Algebraic Geometry (cf. e.g. [11, 17, 30]). The construction of the moduli space $\mathcal{M}_g$ of smooth, genus–$g$ curves (and its generalizations $\mathcal{M}_{g,n}$ of moduli spaces of smooth, $n$–pointed, genus–$g$ curves), the proof of its irreducibility and the construction of a natural compactification of it deeply rely on the use of Hilbert schemes of curves (cf. e.g. [2, 19, 31]). Similarly, together with the Deligne–Mumford compactification of $\mathcal{M}_g$ in [19], the use of Hilbert schemes of curves has been also fundamental in the construction of suitable compactifications of the universal Picard variety (cf. e.g. [10], Theorem, p. 592).

Besides these examples, the use of Hilbert schemes has been fundamental for several other issues in Algebraic Geometry: unirationality and/or Torelli’s type of theorems for cubic hypersurfaces and for prime Fano threefolds of given genus have been proved via the use of Hilbert schemes of lines and planes contained in such varieties (cf. e.g. [26, 18, 7, 23, 41, 27, 34]). Important connections between Hilbert schemes parametrizing $k$–linear spaces contained in complete intersections of hyperquadrics and intermediate Jacobians (cf. [22]) are worth to be mentioned, whereas in [8, 9] the Hilbert schemes of projective scroll surfaces have been related with families of rank–$2$ vector-bundles as well as with moduli spaces of (semi)stable ones. Surjectivity of Gaussian–Wahl maps on curves with general moduli (cf. [15, 16]) has deep reflections both on suitable Hilbert schemes of associated cones and on the extendability of such curves (especially in the $K3$–case). At last, Hilbert schemes parametrizing lines in suitable complete intersections are used either in [11], to deduce upper–bounds of minimal gonality of a family of curves covering a very–general projective hypersurface of high degree, or in [5, 6] to deduce new results concerning either enumerative properties or a certain “algebraic hyperbolicity” behavior.

In the present paper we focus on Hilbert schemes of smooth, irreducible projective curves of given degree and genus, the study of which is classical and goes back to Castelnuovo, Halphen (Castelnuovo bounds and the gap problem) and Severi.

Key words and phrases. Hilbert scheme of curves, Brill–Noether theory, ruled surfaces, cones, coverings, Gaussian–Wahl maps.

This collaboration has benefited of funding from the MIUR Excellence Department Project awarded to the Department of Mathematics, University of Rome Tor Vergata (CUP: E83-C18000100006) and from the MIUR Excellence Department Project awarded to the Department of Mathematics and Physics, University Roma Tre. Both authors are members of INDAM–GNSAGA.
Given non-negative integers $d$, $g$ and $R \geq 3$, we denote by $\mathcal{I}_{d,g,R}$ the union of all irreducible components of the Hilbert scheme whose general points parametrize smooth, irreducible, non-degenerate curves of degree $d$ and genus $g$ in the projective space $\mathbb{P}^R$. A component of $\mathcal{I}_{d,g,R}$ is said to be regular if it is generically smooth and of the expected dimension, otherwise it is said to be superabundant (cf. §11 for more details).

Under suitable numerical assumptions, involving the so called Brill-Noether number, it is well-known that $\mathcal{I}_{d,g,R}$ has a unique irreducible component which dominates the moduli space $\mathcal{M}_g$ parametrizing (isomorphism classes of) smooth, irreducible genus-$g$ curves (cf. [30] and §11 below). This is called the distinguished component of the Hilbert scheme.

In [40], Severi claimed the irreducibility of $\mathcal{I}_{d,g,R}$ when $d\geq g+R$, and this was actually proved by Ein for $R = 3$, 4 in (cf. 21, 25); further sufficient conditions on $d$ and $g$ ensuring the irreducibility of some $\mathcal{I}_{d,g,R}$ for $R \geq 5$ have been found e.g. in [8]. On the other hand, in several cases there have been also given examples of additional non-distinguished components of $\mathcal{I}_{d,g,R}$. Some of these extra components have been constructed by using either $m$–sheeted covers of $\mathbb{P}^1$ (cf. e.g. [35], [37], etc.), or by using double covers of irrational curves (cf. e.g. [12], [13], etc.) or even by using non-linearly normal curves in projective space (Harris, 1984 unpublished, see e.g. [17], Ch. IV).

In this paper we prove the following:

**Main Theorem.** Let $\gamma \geq 10$, $e \geq 2\gamma - 1$, $R = e - \gamma + 1$ and $m \geq 2$ be integers. Set $d := me$ and $g := m(g - 1) + \frac{m(m-1)}{2}e + 1$.

Then $\mathcal{I}_{d,g,R}$ contains an irreducible component which is generically smooth and superabundant, having dimension

$$\lambda_{d,g,R} + \sigma_{d,g,R},$$

where

$$\lambda_{d,g,R} := (R+1)me - (R-3)\left(m(g-1) + \frac{m(m-1)}{2}e\right)$$

is the expected dimension of $\mathcal{I}_{d,g,R}$ whereas the positive integer

$$\sigma_{d,g,R} := (R-4)\left[(\gamma - 1)(m-1) + 1 + e + \frac{m(m-3)}{2}e\right] + 4(e+1) + em(m-5)$$

is the superabundance summand for the dimension of such a component.

As additional result, we explicitly describe a general point of the aforementioned superabundant component (cf. Proposition 2.5 and §8 below). We want to stress that Main Theorem extends some of the results in [12, 13] which deal with the case $m = 2$.

The paper consists of three sections. In Section 1 we remind some generalities concerning Hilbert schemes of curves and associated Brill–Noether theory (cf. §11), Gaussian–Wahl maps and Hilbert schemes of cones (cf. §12) and ramified coverings of curves (cf. §13), which will be used for our analysis. Section 2 deals with the construction of curves $X$ which fill–up an open dense subscheme of the superabundant component of $\mathcal{I}_{d,g,R}$ mentioned in Main Theorem above. Precisely in §2.1 we more generally consider, for any $\gamma \geq 1$ and $e \geq 2\gamma - 1$, curves $Y$ of genus $\gamma$, degree $e$ with general moduli, which are non-special and projectively normal in $\mathbb{P}^{R-1}$ and which fill–up the distinguished component of the related Hilbert scheme $\mathcal{I}_{e,\gamma,R-1}$. Then in §2.2 we consider cones $F = F_Y$ extending in $\mathbb{P}^R$ curves $Y$ as above, we describe abstract resolutions of cones $F$, together with further cohomological properties (see Proposition 2.2), as well as an explicit parametric description of the parameter space of such cones, as $Y$ varies in the distinguished component of $\mathcal{I}_{e,\gamma,R-1}$. In §2.3 we construct the desired curves $X$ as curves sitting in cones $F$ as $m$–sheeted ramified covers $\varphi : X \to Y$, where the map $\varphi$ is given by the projection from the vertex of the cone. We prove that such curves $X$ are non–degenerate and linearly normal in $\mathbb{P}^R$, we moreover compute their genus $g$ and some other useful cohomological properties (cf. Proposition 2.5). We also prove Lemma 2.6 a technical result which deals with a more general situation involving projections and ramified covers of possibly reducible, connected, nodal curves and which is needed for a certain inductive procedure used in proving Main Theorem (see Lemma 3.3 and the proof of Claim 3.5). Finally, Section 3 focuses on the proof of Main Theorem, which also involves surjectivity of suitable Gaussian–Wahl maps (cf. proof of Claim 3.5). This explains why in this last section, as well as in Main Theorem, the hypothesis $\gamma \geq 10$ is required (cf. Proposition 3.2).
Notation and terminology. We work throughout over the field \( \mathbb{C} \) of complex numbers. All schemes will be endowed with the Zariski topology. By variety we mean an integral algebraic scheme and by curve we intend a variety of dimension 1. We say that a property holds for a general point \( x \) of a variety \( X \) if it holds for any point in a Zariski open non–empty subset of \( X \). We will interchangeably use the terms rank-\( r \) vector bundle on a variety \( X \) and rank-\( r \) locally free sheaf. To ease notation and when no confusion arises, we sometimes identify line bundles with Cartier divisors, interchangeably using additive notation instead of multiplicative notation and tensor products; we moreover denote by \( \sim \) the linear equivalence of divisors and by \( \equiv \) their numerical equivalence. If \( \mathcal{P} \) is either a parameter space of a flat family of closed subschemes of a variety \( X \), as e.g. \( \mathcal{P} \) a Hilbert scheme, or a moduli space parametrizing geometric objects modulo a given equivalence relation, as e.g. the moduli space of smooth genus-\( g \) curves, we will denote by \( [Y] \) the parameter point (resp., the moduli point) corresponding to the subscheme \( Y \subset X \) (resp., associated to the equivalence class of \( Y \)). For non–reminded terminology, we refer the reader to [33].

1. Generalities

We briefly recall some generalities and results which will be used in the next sections.

1.1. Hilbert schemes and Brill-Noether theory of curves. Let \( C \) be a smooth, irreducible, projective curve of genus \( g > 0 \). Given positive integers \( d \) and \( r \), the Brill-Noether locus, \( W^r_d(C) \subseteq \text{Pic}^d(C) \), when not empty, parametrizes degree–\( d \) line bundles \( L \) on \( C \) such that \( h^0(C,L) \geq r+1 \). Its expected dimension is given by the so called Brill-Noether number

\[
\rho(g,r,d) := g - (r+1)(g+r-d).
\]

(1.1)

It is well-known that if \( C \) has general moduli (i.e. when \( C \) corresponds to a general point of the moduli space \( \mathcal{M}_g \) parametrizing isomorphism classes of smooth, genus-\( g \) curves) it is well known that \( W^r_d(C) \) is empty if \( \rho(g,r,d) < 0 \), whereas it is generically smooth, of the expected dimension \( \rho(g,r,d) \), otherwise. Moreover, when \( \rho(g,r,d) > 0 \), \( W^r_d(C) \) is also irreducible and for a general \( L \) parametrized by \( W^r_d(C) \) it is \( h^0(C,L) = r+1 \) (cf. [1, Ch. IV, V, VI]).

Brill-Noether theory of line–bundles on abstract projective curves \( C \) is intimately related to the study of Hilbert schemes parametrizing projective embeddings of such curves. Indeed, assume for simplicity \( L \in W^r_d(C) \) very–ample and such that \( h^0(L,C) = r+1 \); hence one has an embedding \( C \to \mathbb{P}^r \) induced by the complete linear system \( |L| \) determined by \( L \), whose image \( Y := \phi|_L(C) \) is a smooth, irreducible curve of degree \( d \), genus \( g \) which is non–degenerate in \( \mathbb{P}^r \). If we denote by \( \text{Hilb}_{d,g,r} \) the Hilbert scheme parametrizing closed subschemes of \( \mathbb{P}^r \) with Hilbert polynomial \( P(t) = dt + (1-g) \), then \( Y \) corresponds to a point of \( \text{Hilb}_{d,g,r} \). If we denote by \( \mathcal{I}_{d,g,r} \) the union of all irreducible components of \( \text{Hilb}_{d,g,r} \) whose general points parametrize smooth, irreducible, non–degenerate curves in \( \mathbb{P}^r \), then \( Y \) represents a point \( [Y] \in \mathcal{I}_{d,g,r} \). When \( [Y] \) is a smooth point of \( \mathcal{I}_{d,g,r} \), then \( Y \) is said to be unobstructed in \( \mathbb{P}^r \).

If \( N_{Y'/\mathbb{P}^r} \) denotes the normal bundle of \( Y \) in \( \mathbb{P}^r \), one has

\[
T_{[Y]}(\mathcal{I}_{d,g,r}) \cong H^0(Y,N_{Y'/\mathbb{P}^r}) \quad \text{and} \quad \chi(Y,N_{Y'/\mathbb{P}^r}) \leq \dim_{[Y]} \mathcal{I}_{d,g,r} \leq h^0(Y,N_{Y'/\mathbb{P}^r}),
\]

(1.2)

where the integer \( \chi(Y,N_{Y'/\mathbb{P}^r}) = h^0(Y,N_{Y'/\mathbb{P}^r}) - h^1(Y,N_{Y'/\mathbb{P}^r}) \) in (1.2) is the so–called expected dimension of \( \mathcal{I}_{d,g,r} \) at \( [Y] \) and the equality on the right–most–side in (1.2) holds iff \( Y \) is unobstructed in \( \mathbb{P}^r \) (for full details, cf. e.g. [39 Cor. 3.2.7, Thm. 4.3.4, 4.3.5]).

The expected dimension of \( \mathcal{I}_{d,g,r} \), given by \( \chi(Y,N_{Y'/\mathbb{P}^r}) \), can be easily computed with the use of normal and Euler sequences for \( Y \subset \mathbb{P}^r \), and it turns out to be

\[
\lambda_{d,g,r} := \chi(Y,N_{Y'/\mathbb{P}^r}) = (r+1)d - (r-3)(g-1).
\]

(1.3)

A component of \( \mathcal{I}_{d,g,r} \) is said to be regular if it is both reduced (i.e. generically smooth) and of the expected dimension \( \lambda_{d,g,r} \); otherwise it is said to be superabundant.

By above, any component \( \mathcal{I} \) of \( \mathcal{I}_{d,g,r} \) has a natural rational map

\[
\mu_g : \mathcal{I} \to \mathcal{M}_g,
\]

which simply sends \( [Y] \in \mathcal{I} \) general to the moduli point \( [C] \in \mathcal{M}_g \) as above. The map \( \mu_g \) is called the modular morphism of \( \mathcal{I} \); with same terminology as in [38 Introduction], the dimension of \( \text{Im}(\mu_g) \) is called the number of moduli of \( \mathcal{I} \).

The expected dimension of \( \text{Im}(\mu_g) \) is \( \min\{3g-3, 3g-3 + \rho(g,r,d)\} \), where \( \rho(g,r,d) \) as in (1.1), and it is called the expected number of moduli of \( \mathcal{I} \). The expression of the expected number of moduli of \( \mathcal{I} \) is the obvious postulation which comes from the well–known interpretation, in terms of maps between vector bundles on Picard scheme, of the
existence of special line bundles on $C$ (cf. [1] Ch. IV, V, VI)). In this set–up, we remind the following result due to Sernesi:

**Theorem 1.1.** (cf. [38, Theorem, p.26]) For any integers $r \geq 2$, $d$ and $g$ such that

$$d \geq r + 1 \quad \text{and} \quad d - r \leq g \leq \frac{(r+1)(d-r)-1}{r}$$

there exists a component $\mathcal{I}$ of $\mathcal{I}_{d,g,r}$ which has the expected number of moduli. Moreover, $[Y] \in \mathcal{I}$ general corresponds to an unobstructed curve $Y \subset \mathbb{P}^r$ such that $h^1(Y, N_{Y/\mathbb{P}^r}) = 0$ and whose embedding in $\mathbb{P}^r$ is given by a complete linear system.

**Remark 1.2.** We want to stress the “geometric counter–part” of the numerical hypotheses appearing in Theorem 1.1. For $Y$ as in Theorem 1.1 let $(C, L)$ be the pair consisting of a smooth, irreducible, abstract projective curve $C$ of genus $g$ and of $L \in \text{Pic}^d(C)$ such that $Y = \phi_{|L|}(C)$. Then, condition $d \geq r + 1$ simply means that the curve $Y$ is of positive genus and non–degenerate in $\mathbb{P}^r$ whereas $d - r \leq g$, i.e. $g + r - d \geq 0$, simply decodes by Riemann–Roch the condition that the index of speciality $i(L) := g + r - d$ of $L$ is non–negative. At last, the condition $g \leq \frac{(r+1)(d-r)-1}{r}$ reads $g - r g + rd - r^2 - 1 \geq 0$ which is nothing but $\rho(g, r, d) + (r + g - d) = \rho(g, r, d) + i(L) \geq 1$, i.e. it is a “Brill-Noether type” condition on the pair $(C, L)$.

It is well known (cf. e.g. [30, p.70]) that, when $\rho(g, r, d) \geq 0$, $\mathcal{I}_{d,g,r}$ has a unique component with a dominant modular morphism $\mu_g$, i.e. dominating $M_g$; thus such a component has maximal number of moduli $3g - 3$. It is called the distinguished component of $\mathcal{I}_{d,g,r}$ and, in the sequel, we will denote it by $\tilde{\mathcal{I}}_{d,g,r}$ or simply by $\tilde{\mathcal{I}}$, if no confusion arises. As a direct consequence of the uniqueness of $\tilde{\mathcal{I}}$ and of Theorem 1.1 one has:

**Corollary 1.3.** For any integers $r \geq 2$, $d$ and $g$ such that

$$d \geq r + 1 \quad \text{and} \quad d - r \leq g \leq \frac{(r+1)(d-r)-1}{r}$$

the distinguished component $\tilde{\mathcal{I}}$ of $\mathcal{I}_{d,g,r}$ is not empty. Its general point $[Y]$ corresponds to an unobstructed curve $Y$ in $\mathbb{P}^r$ with $h^1(Y, N_{Y/\mathbb{P}^r}) = 0$ and whose embedding in $\mathbb{P}^r$ is given by a complete linear system. Furthermore $\tilde{\mathcal{I}}$ is regular, i.e. generically smooth and of the expected dimension $\lambda_{d,g,r}$.

**Proof.** The condition $g \leq \frac{(r+1)(d-r)-1}{r}$ is equivalent to $\rho(g, r, d) \geq 1$. Thus we conclude by applying Theorem 1.1 taking into account what discuss in Remark 1.2 and by applying [30, p.70] and (1.2), as the condition $h^1(Y, N_{Y/\mathbb{P}^r}) = 0$ implies both the non–obstructedness of $Y$ in $\mathbb{P}^r$ and the regularity of $\tilde{\mathcal{I}}$. \hfill $\square$

In [30], Severi claimed the irreducibility of $\mathcal{I}_{d,g,r}$ when $d \geq g + r$. Severi’s claim was proved by Ein for $r = 3, 4$ in (cf. [24,25]): further sufficient conditions on $d$ and $g$ ensuring the irreducibility of some $\mathcal{I}_{d,g,R}$ for $R \geq 5$ have been found e.g. in [8]. On the other hand, in several cases there have been also given examples of additional non–distinguished components of $\mathcal{I}_{d,g,r}$, even in the range $\rho(g, d, r) \geq 0$. Some of these extra components have been constructed by using either $m$–sheeted covers of $\mathbb{P}^1$ (cf. e.g. [35, 37], etc.), or by using double covers of irrational curves (cf. e.g. [12, 13], etc.) or even by using non–linearly normal curves in projective space (the latter approach is contained in a series of examples due to Harris, 1984 unpublished, fully described in e.g. [17, Ch. IV]). In some cases, these extra components have been also proved to be regular (cf. e.g. [17, Ch. IV], [13]).

1.2. **Gaussian-Wahl maps and cones.** Let $C$ be a smooth, irreducible projective curve of positive genus $g$ and $L$ be a very–ample line bundle of degree $d$ on $C$. Set $Y \subset \mathbb{P}^r$ the embedding of $C$ by the complete linear system $|L|$. Let $F_Y$ (equiv., $F_{C,L}$) denote the cone in $\mathbb{P}^{r+1}$ over $Y$ with vertex at a point $v \in \mathbb{P}^{r+1} \setminus \mathbb{P}^r$ (if no confusion arises, in the sequel we simply set $F$).

Fundamental properties of such cones are related to the so–called Gaussian–Wahl maps (cf. e.g. [15,16,42]), as we will briefly remind. If $\omega_C$ denotes the canonical bundle of $C$, one sets

$$R(\omega_C, L) := \text{Ker} \left[ H^0(C, \omega_C) \otimes H^0(C, L) \rightarrow H^0(C, \omega_C \otimes L) \right],$$

where the previous map is a natural multiplication map among global sections. One can consider the map

$$\Phi_{\omega_C,L} : R(\omega_C, L) \rightarrow H^0(\omega_C^\otimes L), \quad (1.4)$$
defined locally by \( \Phi_{\omega_{C,L}}(s \otimes t) := s \, dt - t \, ds \), which is called the Gaussian–Wahl map. As customary, one sets

\[
\gamma_{C,L} := \text{cork}(\Phi_{\omega_{C,L}}) = \dim \text{Coker}(\Phi_{\omega_{C,L}}). \tag{1.5}
\]

For reader’s convenience we will remind here statement of [16 Prop. 2.1], limiting ourselves to its (2.8)–part, which will be used in Section 3 indeed, the full statement of [16 Prop. 2.1] is quite long, with many exceptions and dwells also on curves with low genus whereas Section 3 will focus on curves of genus at least 10.

**Proposition 1.4.** (cf. [16 Proposition 2.1–(2.8)]) Let \( g \geq 6 \) be an integer. Assume that \( C \) is a smooth, projective curve of genus \( g \) with general moduli and that \( L \in \text{Pic}^1(C) \) is general. Then, \( \gamma_{C,L} = 0 \) (i.e. \( \Phi_{\omega_{C,L}} \) is surjective) if

\[
d \geq \begin{cases} 
g + 12 & \text{for } 6 \leq g \leq 8 \\
g + 9 & \text{for } g \geq 9 
\end{cases}.
\]

Gaussian–Wahl maps can be used to compute the dimension of the tangent space to the Hilbert scheme of surfaces in \( \mathbb{P}^{r+1} \) at points representing cones \( F \) as above (cf. e.g. [16]). Indeed, let \( W \) be any irreducible component of the Hilbert scheme of curves \( \mathcal{I}_{d,g,r} \) and let \( \mathcal{H}(W) \) be the variety which parametrizes the family of cones \( F \subset \mathbb{P}^{r+1} \) over curves \( Y \subset \mathbb{P}^r \) representing points in \( W \). Then, one has:

**Proposition 1.5.** (cf. [16 Cor. 2.20–(c), Prop. 2.12–(2.13) and (2.15)]) Set notation and conditions as in Proposition 1.4. Let \( r = d - g, Y \subset \mathbb{P}^r \) and \( W \) be any component of \( \mathcal{I}_{d,g,r} \) s.t. \( [Y] \in W \) is general. Then:

(i) The Gaussian–Wahl map \( \Phi_{\omega_Y,C_Y(1)} \) is surjective, i.e. \( \gamma_{Y,C_Y(1)} = 0 \).

(ii) \( h^0(Y, N_Y/\mathcal{O}_Y(-1)) = r + 1 \).

(iii) \( h^0(Y, N_Y/\mathcal{O}_Y(-j)) = 0 \), for any \( j \geq 2 \).

(iv) \( \mathcal{H}(W) \) is a generically smooth component of the Hilbert scheme parametrizing surfaces of degree \( d \) and sectional genus \( g \) in \( \mathbb{P}^{r+1} \). Moreover,

\[
\dim \mathcal{H}(W) = (r + 1)(d + 1) - (r - 3)(g - 1) = \lambda_{d,g,r} + (r + 1) \tag{1.6}
\]

and it is generically smooth, i.e. for \( [F] \in \mathcal{H}(W) \) general the associated cone \( F = F_Y \) is unobstructed in \( \mathbb{P}^{r+1} \).

### 1.3. Ramified coverings of curves

Let \( Y \) be a scheme. A morphism \( \varphi : X \to Y \) is called a covering map of degree \( m \) if \( \varphi^* \mathcal{O}_Y \) is a locally free \( \mathcal{O}_Y \)-sheaf of rank \( m \). A map \( \varphi \) is a covering map (or simply a cover) if and only if it is finite and flat. In particular, if \( Y \) is smooth and irreducible and \( X \) is Cohen–Macaulay, then every finite, surjective morphism \( \varphi : X \to Y \) is a covering map (cf. e.g. [11 p. 1361]).

When \( \varphi : X \to Y \) is a covering map of degree \( m \), one has a natural exact sequence

\[
0 \to \mathcal{O}_Y \xrightarrow{\varphi^*} \varphi^* \mathcal{O}_X \to \mathcal{T}_{\varphi}^Y \to 0,
\]

where \( \mathcal{T}_{\varphi}^Y := \text{Coker}(\varphi^*) \) is the so-called Tschirnhausen bundle associated to the covering map \( \varphi \), which is of rank \( m - 1 \) on \( Y \). Since \( \text{Char} \,(\mathbb{C}) = 0 \), the trace map \( \text{tr} : \varphi^* \mathcal{O}_X \to \mathcal{O}_Y \) gives rise to a splitting of the previous exact sequence, so that one has \( \varphi^* \mathcal{O}_X = \mathcal{O}_Y \oplus \mathcal{T}_{\varphi}^Y \) (cf. e.g. [11 13 20 21]).

If \( X \) and \( Y \) are in particular smooth, irreducible curves and \( \varphi : X \to Y \) is a covering map of degree \( m \), according to [23 Ex. IV.2.6–(d), p. 306], the branch divisor \( B_{\varphi} \) of \( \varphi \) is such that

\[
\left( \bigwedge^m(\varphi^* \mathcal{O}_X) \right)^{\otimes 2} \cong \mathcal{O}_Y(-B_{\varphi}). \tag{1.7}
\]

If moreover \( X \) (resp., \( Y \)) has genus \( g \) (resp., \( \gamma \)) then one has \( \deg B_{\varphi} = -2 \deg \left( \bigwedge^m(\varphi^* \mathcal{O}_X) \right) = 2(g - 1) - 2m(\gamma - 1) \). As for the ramification divisor \( R_{\varphi} \) such that \( \varphi(R_{\varphi}) = B_{\varphi} \), the Riemann–Hurwitz formula gives

\[
\omega_X = \varphi^*(\omega_Y) + \mathcal{O}_X(R_{\varphi}). \tag{1.8}
\]

In this set–up, we recall the pinching construction described in [21 § 3.1]. Let \( \varphi : X \to Y \) be a degree–\( m \) covering map between smooth irreducible curves \( X \) and \( Y \). Let \( Z \) be the reduced, reducible nodal curves

\[
Z := X \cup Y,
\]

where \( X \) and \( Y \) are attached nodally at \( \delta \) distinct points as follows: let \( y_i \in Y \) and \( x_i \in X \) be points such that \( \varphi(x_i) = y_i, 1 \leq i \leq \delta \). Set \( D := \sum_{i=1}^{\delta} y_i \), \( \mathcal{O}_D \) the structural sheaf of \( D \) and \( J \) the kernel of the map

\[
\varphi_* \mathcal{O}_X \oplus \mathcal{O}_Y \to \mathcal{O}_D,
\]
defined around any \( y_i \)'s as

\[ (f, g) \mapsto f(x_i) - g(y_i), \quad \forall \ 1 \leq i \leq \delta. \]

Then \( J \subset \varphi_* \mathcal{O}_X \oplus \mathcal{O}_Y \) is an \( \mathcal{O}_Y \)-subalgebra of \( \varphi_* \mathcal{O}_X \oplus \mathcal{O}_Y \) and \( \text{Spec}_Y(J) = Z = X \cup Y \). \( D \) is called the set of nodes of \( Z \). Let \( \psi : Z \to Y \) be the natural induced finite and surjective map. Since \( Y \) is smooth, irreducible and \( Z \) is l.c.i. (so in particular Cohen–Macaulay), from what reminded above the map \( \psi \) is a covering map of degree \( m + 1 \). In this set–up, one has the following:

**Proposition 1.6.** (cf. [21] Lemma 3.2) Let \( \varphi : X \to Y \) be a covering map of degree–\( m \) between smooth irreducible curves \( X \) and \( Y \). Let \( \psi : Z \to Y \) be the covering map of degree \( m + 1 \) induced by the pinching construction whose set of nodes is \( D \). Then, the following exact sequence of vector bundles on \( Y \)

\[ 0 \to \mathcal{T}_\varphi \to \mathcal{T}_\psi \to \mathcal{O}_Y(D) \to 0 \]

holds, where \( \mathcal{T}_\varphi \) and \( \mathcal{T}_\psi \) are the Tschirnhausen bundles associated to the covering maps \( \varphi \) and \( \psi \), respectively.

2. Curves and cones

In this section we first construct families of non–special curves \( Y \) of any positive genus \( \gamma \) and of degree \( e \geq 2\gamma - 1 \) in a projective space, which turn out to fill–up the distinguished component \( \mathcal{I} \) of the related Hilbert scheme (cf. §2.1). After that, we deal with the family \( \mathcal{H}(\mathcal{I}) \), as in §1.2, which parametrizes cones extending curves in \( \mathcal{I} \), i.e. cones having curves in \( \mathcal{I} \) as hyperplane sections. We describe an abstract resolution of a general point of \( \mathcal{H}(\mathcal{I}) \), and compute \( \dim \mathcal{H}(\mathcal{I}) \) via an explicit parametric description (cf. §2.2). To conclude the section, for cones \( F \) parametrized by \( \mathcal{H}(\mathcal{I}) \) we construct smooth, irreducible curves \( X \subset F \), of suitable degree \( d \) and genus \( g \), which turn out to be \( m \)-sheeted ramified covers of curves \( Y \) varying in the distinguished component \( \mathcal{I} \) (cf. §2.3).

2.1. Curves in distinguished components. Let \( \gamma > 0 \) and \( e \geq 2\gamma - 1 \) be integers. Let \( C \) be a smooth, irreducible, projective curve of genus \( \gamma \) and let \( \mathcal{O}_C(E) \in \text{Pic}^e(C) \) be a general line bundle. Thus, \( \mathcal{O}_C(E) \) is very–ample and non–special (i.e. \( h^1(C, \mathcal{O}_C(E)) = 0 \)). By Riemann-Roch, we set

\[ R := h^0(C, \mathcal{O}_C(E)) = e - \gamma + 1, \quad (2.1) \]

so that \( [\mathcal{O}_C(E)] \) defines an embedding \( C \xrightarrow{\phi_E} \mathbb{P}^{R-1} \), whose image we denote from now on by \( Y := \phi_E(C) \). Taking into account [20] Thm. 1], we therefore have:

\( Y \) is a smooth, projective curve of genus \( \gamma > 0 \), degree \( e \geq 2\gamma - 1 \), which is projectively normal in \( \mathbb{P}^{R-1} \). (2.2)

As in §1.1, one has in particular that \( [Y] \in \mathcal{I}_{e,\gamma,R-1} \).

If we let vary \([C] \in \mathcal{M}_\gamma\), and, for any such \( C \), we let \( \mathcal{O}_C(E) \) vary in \( \text{Pic}^e(C) \), the next result shows that the corresponding curves \( Y \subset \mathbb{P}^{R-1} \) fill–up the distinguished component \( \mathcal{I} := \mathcal{I}_{e,\gamma,R-1} \) which also turns out to be regular.

**Proposition 2.1.** Let \( \gamma > 0 \) and \( e \geq 2\gamma - 1 \) be integers. Let \( C \) be a smooth, projective curve of genus \( \gamma \) with general moduli, and let \( \mathcal{O}_C(E) \in \text{Pic}^e(C) \) be a general line bundle. Let \( Y := \phi_E(C) \subset \mathbb{P}^{R-1} \), where \( R = e - \gamma + 1 \). Then, \( Y \) is a smooth, irreducible curve of degree \( e \) and genus \( \gamma \) which is projectively normal in \( \mathbb{P}^{R-1} \), as an embedding of \( C \) via the complete linear system \( |E| \), and such that \( h^1(Y, N_{Y/\mathbb{P}^{R-1}}) = 0 \). It corresponds to a general point of the distinguished component \( \mathcal{I} := \mathcal{I}_{e,\gamma,R-1} \) of the Hilbert scheme \( \mathcal{I}_{e,\gamma,R-1} \), which is regular of dimension

\[ \dim \mathcal{I} = \lambda_{e,\gamma,R-1} = Re - (R - 4)(\gamma - 1). \quad (2.3) \]

**Proof.** Numerical assumptions and [20] Thm. 1 imply that \( E \) is very–ample, non–special and that \( Y \subset \mathbb{P}^{R-1} \) is projectively normal, the equality \( R = e - \gamma + 1 \) simply following by the non–speciality of \( E \) and by Riemann-Roch.

Under our assumptions, numerical hypotheses in Corollary 1.3 hold true. Indeed, as explained in Remark 1.2 we have the following: since \( Y \subset \mathbb{P}^{R-1} \) is non–degenerate and of positive genus \( \gamma \), then condition \( e \geq R \) is certainly satisfied; concerning condition \( e \geq e - (R - 1) \), i.e. \( i(E) \geq 0 \), it certainly holds from the non–speciality of \( E \); at last, non–speciality of \( E \) gives \( \rho(\gamma, R - 1, e) + i(E) = \rho(\gamma, R - 1, e) = \gamma \geq 1 \), therefore \( \gamma \leq \frac{R(e - (R - 1))}{e - (R - 1)} \) as in Corollary 1.3 certainly holds (cf. Remark 1.2).

Thus, by Corollary 1.3 \( [Y] \) corresponds to a point in the distinguished component \( \mathcal{I} \) of \( \mathcal{I}_{e,\gamma,R-1} \) and is such that \( h^1(Y, N_{Y/\mathbb{P}^{R-1}}) = 0 \), i.e. \( \mathcal{I} \) is generically smooth and of the expected dimension \( \lambda_{e,\gamma,R-1} \) which equals \( Re - (R - 4)(\gamma - 1) \), as it follows from 1.3. \( \square \)
2.2. Cones extending curves in \( \tilde{\mathcal{I}} \). With notation as in Section 2.2 here we will deal with the family of cones \( \mathcal{H}(\tilde{\mathcal{I}}) \), where \( \tilde{\mathcal{I}} = \mathcal{I}_{e, \gamma, R-1} \) is the distinguished component in Proposition 2.1 above. For \( [Y] \in \tilde{\mathcal{I}} \) general, we will denote by \( F := F_Y \subset \mathbb{P}^R \) a cone over \( Y \) with general vertex \( v \in \mathbb{P}^R \setminus \mathbb{P}^{R-1} \). In order to describe suitable smooth, abstract resolution of the cones \( F \), we recall the following general facts.

Let \( C \) be a smooth, irreducible projective curve of genus \( \gamma > 0 \) and let \( \mathcal{O}_C(E) \in \text{Pic}^e(C) \) be a general line bundle of degree \( e \geq 2\gamma - 1 \). Consider the rank–two, normalized vector bundle \( \tilde{\mathcal{I}} := \mathcal{O}_C \oplus \mathcal{O}_C(-E) \) on \( C \) and let \( S := \mathbb{P}(\tilde{\mathcal{I}}) = \text{Proj}\_C(\text{Sym}(\tilde{\mathcal{I}})) \) the associated geometrically ruled surface on \( C \). One has the structural morphism \( \rho : S \to C \) such that \( \rho^{-1}(p) = f_p \), for any \( p \in C \), where \( f_p \cong \mathbb{P}^1 \) denotes the fiber of the ruling of \( S \) over the point \( p \in C \). A general fiber of the ruling of \( S \) will be simply denoted by \( f \).

\( S \) is endowed with two natural sections, \( C_0 \) and \( C_1 \), both isomorphic to \( C \), and such that \( C_0 \cdot C_1 = 0 \), \( C_0^2 = -C_1^2 = -e \). The section \( C_0 \) (resp., \( C_1 \)) corresponds to the exact sequence

\[
0 \to \mathcal{O}_C \to \tilde{\mathcal{I}} \to \mathcal{O}_C(-E) \to 0 \quad (\text{resp.}, \quad 0 \to \mathcal{O}_C(-E) \to \tilde{\mathcal{I}} \to \mathcal{O}_C \to 0).
\]

Moreover, one has \( \text{Pic}(S) \cong \mathbb{Z}[\mathcal{O}_S(C_0)] \oplus \rho^*(\text{Pic}(C)) \) and \( \text{Num}(S) \cong \mathbb{Z} \oplus \mathbb{Z} \) (cf. e.g. [33, V.2]). To ease notation, for any \( D \in \text{Div}(C) \), we will simply set \( \rho^*(D) := D_f \).

If \( K_S \) (resp., \( K_C \)) denotes a canonical divisor of \( S \) (resp., of \( C \)), one has (cf. e.g. [33, V.2]):

\[
C_1 \sim C_0 + E f \quad \text{and} \quad K_S \sim -2C_0 + (K_C - E)f.
\]

Proposition 2.2. Let \( C \) be a smooth, irreducible projective curve of genus \( \gamma > 0 \) and \( \mathcal{O}_C(E) \in \text{Pic}^e(C) \) be a general line bundle of degree \( e \geq 2\gamma - 1 \). Consider the normalized, rank–two vector bundle \( \tilde{\mathcal{I}} := \mathcal{O}_C \oplus \mathcal{O}_C(-E) \) on \( C \) and let \( S := \mathbb{P}(\tilde{\mathcal{I}}) \), together with the natural sections \( C_0 \) and \( C_1 \), where \( C_1 \sim C_0 + E f \), \( C_0 \cdot C_1 = 0 \), \( C_0^2 = -C_1^2 = -e \). Then:

(i) The linear system \( |\mathcal{O}_S(C_1)| \) is base–point–free and not composed with a pencil. It induces a morphism

\[
\Psi := \Psi_{|\mathcal{O}_S(C_1)|} : S \to \mathbb{P}^R,
\]

where \( R = e - \gamma + 1 \).

(ii) \( \Psi \) is an isomorphism, outside the section \( C_0 \subset S \), onto its image \( F := \Psi(S) \subset \mathbb{P}^R \), whereas it contracts \( C_0 \) at a point \( v \in \mathbb{P}^R \).

(iii) \( F \) is a cone of vertex \( v \) over \( Y := \Psi(C_1) \cong C \), where \( Y \subset \mathbb{P}^{R-1} \) is a hyperplane section of \( F \) not passing through \( v \), which is smooth, irreducible, non-degenerate, of degree \( e \), genus \( \gamma \) and it is also projectively normal in \( \mathbb{P}^{R-1} \).

(iv) The cone \( F \subset \mathbb{P}^R \) is projectively normal, of degree \( \deg F = e \), of sectional genus and speciality \( \gamma \). In particular, \( h^0(F, \mathcal{O}_F(1)) = R + 1 = e - \gamma + 2 \) and \( h^1(F, \mathcal{O}_F(1)) = \gamma \).

(v) For any \( m \geq 2 \), one has \( h^0(F, \mathcal{O}_F(m)) = \frac{m(m+1)}{2} e - m(\gamma - 1) + 1 \).

Proof. (i) From [33, Ex. V.2.11 (a), p. 386] one deduces that \( |\mathcal{O}_S(C_1)| \) is base–point–free and not composed with a pencil. Therefore \( \Psi \) is a morphism and its image is a surface. Now, from [28, 4.1], we have

\[
h^0(S, \mathcal{O}_S(C_1)) = h^0(S, \mathcal{O}_S(C_0 + Ef)) = h^0(C, \mathcal{O}_C(E)) + h^0(C, \mathcal{O}_C) = (e - \gamma + 1) + 1 = R + 1,
\]

where the second equality follows from Leray’s isomorphism, projection formula and the fact that

\[
\rho_* (\mathcal{O}_S(C_0 + Ef)) = \rho_* (\mathcal{O}_S(C_0) \otimes \mathcal{O}_S(Ef)) = \tilde{\mathcal{I}} \otimes \mathcal{O}_C(E) = (\mathcal{O}_C \otimes \mathcal{O}_C(-E)) \otimes \mathcal{O}_C(E) = \mathcal{O}_C(E) \otimes \mathcal{O}_C,
\]

whereas the third and the last equality follow, respectively, from the fact that \( E \) is non-special of degree \( e \) on \( C \) of genus \( \gamma \) and from [2.1].

(ii) Since \( E \) is very–ample on \( C \), [28, Prop. 23] implies that the morphism \( \Psi \) is an isomorphism onto its image \( F \) outside the section \( C_0 \) of \( S \). On the other hand, \( C_1 \cdot C_0 = (C_0 + Ef) \cdot C_0 = -e + e = 0 \), i.e. \( C_1 \) contracts the section \( C_0 \) at a point \( v \in \mathbb{P}^R \) which is off \( Y = \Psi(C_1) \), the isomorphic image of the section \( C_1 \cong C \).

(iii) All the fibers of the ruling of \( S \) are embedded as lines, as \( C_1 \cdot f = 1 \). Since \( C_0 \) is contracted to a point \( v \) and since \( C_0 \cdot f = 1 \), for any fiber \( f \) of the ruling of \( S \), it follows that any line \( \ell \in \Psi(f) \) passes through \( v \); thus \( F = \Psi(S) \) is a cone over \( Y \), of vertex \( v \in \mathbb{P}^R \). From the isomorphism \( C_1 \cong C \), one also deduces \( \Psi_{|C_1} \cong \phi|\mathcal{O}_C(E)| \), as the following diagram summarizes:

\[
\begin{array}{ccc}
S & \xrightarrow{\Psi_{|\mathcal{O}_S(C_1)|}} & F \subset \mathbb{P}^R \\
\downarrow^\rho & & \downarrow^\pi_v \\
C & \xrightarrow{\phi|\mathcal{O}_C(E)|} & Y \subset \mathbb{P}^{R-1},
\end{array}
\]

(2.5)
where \( \pi_v \) denotes the projection from the vertex point \( v \). Since \( \mathcal{O}_F(1) \) is induced by \( \mathcal{O}_S(1) \), it is clear that \( Y \) is a hyperplane section of \( F \) so \( Y \subset \mathbb{P}^{R-1} \) is of degree \( e \), genus \( \gamma \) and it is projectively normal in \( \mathbb{P}^{R-1} \), as it follows from \([29]\) Thm. 1].

(iv) One has \( \deg F = Y^2 = C_1^2 = e \); moreover, since \( Y \cong C \) is a hyperplane section, then \( F \) has sectional genus \( \gamma \). Now, \( h^0(F, \mathcal{O}_F(1)) = h^0(C, \mathcal{O}_S(C_1)) = R + 1 = e - \gamma + 2 \), as computed in (i); whereas \( h^1(F, \mathcal{O}_F(1)) = h^1(S, \mathcal{O}_S(C_1)) \) so, from the exact sequence

\[
0 \to \mathcal{O}_S \to \mathcal{O}_S(C_1) \xrightarrow{rc_1} \mathcal{O}_C(C_1) \cong \mathcal{O}_C(E) \to 0
\]

one gets

\[
h^0(S, \mathcal{O}_S(C_1)) = R + 1, \quad h^0(C, \mathcal{O}_C(C_1)) = h^0(C, \mathcal{O}_C(E)) = R, \quad h^1(C, \mathcal{O}_C(C_1)) = h^1(C, \mathcal{O}_C(E)) = 0,
\]

as \( E \) is non–special. By Leray’s isomorphism and projection formula one also gets \( h^1(S, \mathcal{O}_S) = h^1(C, \mathcal{O}_C) = \gamma \). Thus the map \( H^0(rc_1) \), induced in cohomology by the map \( rc_1 \), is surjective hence, from the above exact sequence, one gets \( h^1(S, \mathcal{O}_S(C_1)) = \gamma \).

At last, since \( F \) has general hyperplane section which is a projectively normal curve in \( \mathbb{P}^{R-1} \), it follows that \( F \) is projectively normal in \( \mathbb{P}^R \) (cf. e.g. \([8]\) Proof of Lemma 5.7, Rem. 5.8).

(v) By the very definition of \( F \), one has \( h^0(F, \mathcal{O}_F(m)) = h^0(S, \mathcal{O}_S(mC_1)) \). From \([33]\) Ex. III.8.3, p. 253] it follows that

\[
h^0(S, \mathcal{O}_S(mC_1)) = h^0(S, \mathcal{O}_S(mC_0 + mE_f)) = \sum_{k=0}^m h^0(C, \mathcal{O}_C((m-k)E)) = \sum_{j=0}^m h^0(C, \mathcal{O}_C(jE)).
\]

Since \( E \) is non–special on \( C \), so it is any divisor \( jE \), for any integer \( 1 \leq j \leq m \). Therefore, by Riemann–Roch on \( C \), one has

\[
h^0(F, \mathcal{O}_F(m)) = \sum_{j=0}^m h^0(C, \mathcal{O}_C(jE)) = 1 + 1 + 3 + \ldots + (m - 1) + m | e - m\gamma + m| = m(m + 1) - e - m(\gamma - 1) + 1,
\]

as stated.

Proposition \([22]\) allows to give an explicit parametric description of the family of cones \( \mathcal{H}(\widehat{L}) \), where \( \widehat{L} := \mathcal{L}_{e, \gamma, R-1} \) is the distinguished component of the Hilbert scheme \( \mathcal{L}_{e, \gamma, R-1} \) as in Proposition \([21]\). For reader’s convenience, we first report here a special case of \([29]\) Lemma 6.3, which is needed for the parametric description of \( \mathcal{H}(\widehat{L}) \).

**Lemma 2.3.** With notation and assumptions as in Proposition \([22]\) assume further that \( \text{Aut}(C) = \{\text{Id}\} \) (this, in particular, happens when e.g. \( C \) has general moduli). Let \( G_F \subset \text{PGL}(R + 1, \mathbb{C}) \) denote the projective stabilizer of \( F \), i.e. the sub-group of projectivities of \( \mathbb{P}^R \) which fix \( F \) as a cone.

Then \( G_F \cong \text{Aut}(S) \) and \( \dim G_S = h^0(C, \mathcal{O}_C(E)) + 1 = R + 1 = e - \gamma + 2 \).

**Proof.** There is an obvious inclusion \( G_F \hookrightarrow \text{Aut}(S) \); we want to show that this is actually a group isomorphism.

Let \( \sigma \in \text{Aut}(S) \) be any automorphism of \( S \). Since \( C_0 \) is the unique section of \( S \) with negative self-intersection, then \( \sigma(C_0) = C_0 \), i.e. \( \sigma \) induces an automorphism of \( C_0 \cong C \). Assumption \( \text{Aut}(C) = \{\text{Id}\} \) implies that \( \sigma \) fixes \( C_0 \) pointwise. Now, from the fact that \( C_1 \sim C_0 + E_f \), it follows that \( \sigma^*(C_1) \sim \sigma^*(C_0) + \sigma^*(E_f) = C_0 + E_f \sim C_1 \). Therefore, since \( |C_1| \) corresponds to the hyperplane linear system of \( F = \Psi(S) \), one deduces that any automorphism \( \sigma \in \text{Aut}(S) \) is induced by a projective transformation of \( F \).

The rest of the proof directly follows from cases \([36]\) Theorem 2–(2) and (3)] and from \([36]\) Lemma 6]: indeed condition \( \text{Aut}(C) = \{\text{Id}\} \) implies that \( \text{Aut}(S) \cong \text{Aut}_C(S) \); furthermore, since \( C_0 \) is the unique section of negative self-intersection on \( S \), \( \dim G_S = h^0(C, \mathcal{O}_C(E)) + 1 \) follows by using the description of \( \text{Aut}_C(S) \) in \([36]\) Theorem 2].

With the use of Proposition \([22]\) and of Lemma \([2.3]\) one can explicitly describe the family of cones \( \mathcal{H}(\widehat{L}) \), where \( \widehat{L} \) the distinguished component in Proposition \([21]\) and also compute its dimension.

**Parametric description of \( \mathcal{H}(\widehat{L}) \):** letting \( |C| \) vary in \( M_\gamma \) and, for any such \( C \), letting \( \mathcal{O}_C(E) \) vary in \( \text{Pic}^e(C) \), cones \( F \) arising as in Proposition \([22]\) fill-up the component \( \mathcal{H}(\widehat{L}) \), which depends on the following parameters:

- \( 3\gamma - 3 \), since \( |C| \) varies in \( M_\gamma \), plus
- \( \gamma \), which are the parameters on which \( \mathcal{O}_C(E) \in \text{Pic}^e(C) \) depends, plus
- \( (R + 1)^2 - 1 = \dim \text{PGL}(R + 1, \mathbb{C}) \), minus
• \( \dim G_F \), which is the dimension of the projectivities of \( \mathbb{P}^R \) fixing a general \( F \) arising from this construction.

From Lemma 2.3 it follows that \( \dim G_F = R + 1 \), so

\[
\dim \mathcal{H}(\hat{\mathcal{I}}) = 4\gamma - 3 + (R + 1)^2 - (R + 2).
\] (2.6)

From Proposition 2.1 we know that \([Y] \in \hat{\mathcal{I}}\) general has \( h^1(Y, N_{Y/\mathbb{P}^R}) = 0 \); moreover, since \( R = e - \gamma + 1 \), it is a straightforward computation to notice that the expression in (2.6) equals the expression in (1.6) with the choice \( \mathcal{W} = \hat{\mathcal{I}} \), \( r = R - 1 \), \( d = e \) and \( g = \gamma \), namely

\[
\dim \mathcal{H}(\hat{\mathcal{I}}) = R(e + 1) - (R - 4)(\gamma - 1) = \lambda_{e, \gamma, R - 1} + R.
\] (2.7)

**Remark 2.4.** The previous parametric description of \( \mathcal{H}(\hat{\mathcal{I}}) \) can be formalized by taking into account the schematic construction of \( \mathcal{H}(\hat{\mathcal{I}}) \) which deals with universal Picard varieties over \( \mathcal{M}_1 \). To do so, we follow procedure as in [13, §2]. Let \( \mathcal{M}_0^e \) be the Zariski open subset of the moduli space \( \mathcal{M}_1 \), whose points correspond to isomorphism classes of curves of genus \( g \) without non-trivial automorphisms. By definition, \( \mathcal{M}_0^e \) is a fine moduli space, i.e. it has a universal family \( p : C \to \mathcal{M}_0^e \), where \( C \) and \( \mathcal{M}_0^e \) are smooth schemes and \( p \) is a smooth morphism. \( C \) can be identified with the Zariski open subset \( \mathcal{M}^{0,1}_{\gamma,1} \) of the moduli space \( \mathcal{M}_{\gamma,1} \) of smooth, 1–pointed, genus–\( \gamma \) curves, whose points correspond to isomorphism classes of \( \{(C, x)\} \), with \( x \in C \) a point and \( C \) a smooth curve of genus \( \gamma \) without non-trivial automorphisms. On \( \mathcal{M}^{0,1}_{\gamma,1} \) there is again a universal family \( p_1 : C_1 \to \mathcal{M}^{0,1}_{\gamma,1} \), where \( C_1 = C \times_{\mathcal{M}_0^e} C \). The family \( p_1 \) has a natural regular global section \( \delta \) whose image is the diagonal. By means of \( \delta \), for any integer \( k \), we have the universal family of Picard varieties of order \( k \) over \( \mathcal{M}^{0,1}_{\gamma,1} \), i.e.

\[
p_{(k)} : \mathcal{P}ic^{(k)} \to \mathcal{M}^{0,1}_{\gamma,1}
\]

(cf. [14 §2]) and, setting \( \mathcal{Z}_k := C_1 \times_{\mathcal{M}^{0,1}_{\gamma,1}} \mathcal{P}ic^{(k)} \), we have a Poincaré line-bundle \( L_k \) on \( \mathcal{Z}_k \) (cf. a relative version of [1, p. 166–167]). For any closed point \((C, x) \in \mathcal{M}^{0,1}_{\gamma,1}\) its fibre via \( p_{(k)} \) is isomorphic to \( \mathcal{P}ic^{(k)}(C) \).

Take \( k = e \geq 2\gamma - 1 \) and let \( \pi_2 : C_\infty \to \mathcal{P}ic^{(e)} \) be the projection onto the second factor. For a general point \( u := [(C, x), \mathcal{O}_C(E)] \in \mathcal{P}ic^{(e)} \), the restriction of \( L_u \) to \( \pi_2^{-1}(u) \) is isomorphic to \( \mathcal{O}_C(E) \in \mathcal{P}ic^{e}(C) \) for \( [(C, x) \in \mathcal{M}^{0,1}_{\gamma,1} \) general; one has \( C_\infty:= \mathcal{O}_\infty \oplus L_u \) as a rank–two vector bundle on \( C_\infty \).

The fibre of \( L_u \) over \( u = [(C, x), \mathcal{O}_C(E)] \in \mathcal{P}ic^{(e)} \) is the rank–two vector bundle \( C_\infty\langle \gamma \rangle = \tilde{\gamma}_u(E) := \mathcal{O}_C \oplus \mathcal{O}_C(E) \) on \( C \), where \( \tilde{\gamma}_u = \mathcal{O}_C(-E) \oplus \mathcal{O}_C \) as in [2.2] and where \( [(C, x) \in \mathcal{M}^{0,1}_{\gamma,1} \) is general. Moreover, the sheaf \( (\pi_2)^*(C_\infty) \) is free of rank \( R + 1 = e - \gamma + 2 \) on a suitable dense, open subset \( \mathcal{U} \) of \( \mathcal{P}ic^{(e)} \); therefore, on \( \mathcal{U} \), we have functions \( s_0, \ldots, s_R \) such that, for each point \( u \in \mathcal{U} \), \( s_0, \ldots, s_R \) computed at \( u = [(C, x), \mathcal{O}_C(E)] \) span the space of sections of the corresponding vector bundle \( \mathcal{E}_u = \tilde{\gamma}_u(E) \).

There is a natural morphism

\[
\Psi_e : \mathcal{P}ic^{(e)} \times \mathbb{P}(R + 1, \mathbb{C}) \to \mathbb{P}(R + 1, \mathbb{C})
\]

where \( \Psi(e, \gamma, R) \) denotes the Hilbert scheme of surfaces in \( \mathbb{P}^R \) of degree \( e \) and sectional genus \( \gamma \); given a pair \((u, \omega)\), embed \( S_u := \mathbb{P}(\mathcal{E}_u) \) to \( \mathbb{P}^R \) via the sections \( s_0, \ldots, s_R \) computed at \( u \), compose with the projectivity \( \omega \) and take the image. Since \( \mathcal{P}ic^{(e)} \times \mathbb{P}(R + 1, \mathbb{C}) \) is irreducible, by Proposition 2.2 \( \mathcal{H}(\hat{\mathcal{I}}) \) is the closure of the image of the above map to the Hilbert scheme. By construction, \( \mathcal{H}(\hat{\mathcal{I}}) \) dominates \( \mathcal{M}_\gamma \) and its general point represents a cone \( F \subset \mathbb{P}^R \), as in Proposition 2.2. From the previous construction, for \( [F] \in \mathcal{H}(\hat{\mathcal{I}}) \) general, one has \( \dim \Psi^{-1}([F]) = \dim G_F + 1 \). From Lemma 2.3 one has \( \dim G_F = R + 1 \) so \( \dim \mathcal{H}(\hat{\mathcal{I}}) = 4\gamma - 3 + (R + 1)^2 - (R + 2) \) as in (2.6).

2.3. Curves on cones and ramified coverings. In this section, we construct suitable ramified \( m \)–covers of \( Y \subset \mathbb{P}^{R-1} \), for \( [Y] \in \hat{\mathcal{I}} \) general in the distinguished component \( \hat{\mathcal{I}} \), with the use of cones \( F \) parametrized by \( \mathcal{H}(\hat{\mathcal{I}}) \). Our approach extends the strategy used in [13], which deals with double covers.

Using notation and assumptions as in Proposition 2.2 for any integer \( m \geq 1 \), let \( C_m \in \mathcal{O}_S(mC_1) \) be a general member of the linear system on \( S \) and let \( X_m := \Psi(C_m) \subset F \) denote its image.

**Proposition 2.5.** For any integer \( m \geq 1 \), one has:

(i) \( X_m \) is a smooth, irreducible curve of degree \( \deg X_m = me \), which is non–degenerate and linearly normal in \( \mathbb{P}^R \).

(ii) \( X_m \) is obtained by the intersection of the cone \( F \) with a hypersurface of degree \( m \) in \( \mathbb{P}^R \).

(iii) The projection \( \pi_v \) from the vertex \( v \in F \) gives rise to a morphism \( \varphi_m : X_m \to Y \), which is a degree–\( m \) covering map induced on \( X_m \) by the ruling of the cone \( F \).
(iv) The geometric genus of $X_m$ is
\[ g_m := g(X_m) = m(\gamma - 1) + \frac{m(m-1)}{2}e + 1. \] (2.8)

(v) For any $j \geq m$, the line bundle $O_{X_m}(j)$ is non-special and such that
\[ h^0(X_m, O_{X_m}(j)) = jme - m(\gamma - 1) - \frac{m(m-1)}{2}e, \quad \forall \ j \geq m. \] (2.9)

Proof. For $m = 1$, $X_1 = Y$ as in Proposition 2.2 and there is nothing else to prove. Therefore, from now on we will focus on $m \geq 2$.

(i) Since $C_m$ is a smooth, irreducible curve on $S$ and since $C_m \cdot C_0 = mC_1 \cdot C_0 = 0$, then $C_m$ is isomorphically embedded via $\Psi$ onto its image $X_m \subset F \subset \mathbb{P}^R$, which does not pass through the vertex $v \in F$. Moreover, $\deg X_m = C_m \cdot C_1 = mC_1 \cdot C_1 = mC_1^2 = me$.

Tensoring the exact sequence defining $C_m$ on $S$ by $O_S(1)$, we get
\[ 0 \to O_S((1-m)C_1) \to O_S(C_1) \xrightarrow{\gamma_1} O_{C_m}(1) \cong O_{X_m}(1) \to 0. \]
Since $m \geq 2$, then $h^0(O_S((1-m)C_1)) = 0$. Moreover, by Serre duality,
\[ h^1(S, O_S((1-m)C_1)) = h^1(S, \omega_S \otimes O_S((m-1)C_1)). \]
From the facts that $\Psi$ is birational, $C_1^2 = e > 0$ and $(m-1) > 0$, it follows that $O_S((m-1)C_1)$ is big and nef, so $h^1(S, \omega_S \otimes O_S((m-1)C_1)) = 0$, by Kawamata–Viehweg vanishing theorem. Thus,
\[ H^0(X_m, O_{X_m}(1)) \cong H^0(C_m, O_{C_m}(1)) \cong H^0(S, O_S(C_1)) \]
which implies that $X_m$ is non-degenerate and linearly normal, as it follows from Proposition 2.2-(iv).

(ii) Since $C_m \sim mC_1$ on $S$ and since $C_1$ induces the hyperplane section of $F$, it follows that $X_m \in |O_F(m)|$.

(iii) Taking into account diagram (2.5), the projection from the vertex $v$ induces the morphism $\varphi_m$. Since $C_m \cdot f = mC_1 \cdot f = m$ and since any fiber $f$ is embedded by $\Psi$ as a line of $F$, $\varphi_m$ is induced by the ruling of the cone. As $Y$ is smooth, irreducible and all the fibers of $\varphi_m$ have constant length $m$, then $\varphi_m$ is a finite, flat morphism from $X_m$ to $Y$ (cf. e.g. 39). Therefore, $\varphi_m$ is a covering map of degree $m$ as in §1.3

(iv) The genus of $X_m$ equals the genus of $C_m$. Therefore, to compute $g_m$ we can apply adjunction formula on $S$ and the Riemann–Hurwitz formula as in (2.3) to the map $\varphi_m : C_m \to C_1$ induced by the fibers of the ruling of $S$ (to ease notation, we use the same symbol as for the map $\varphi_m : X_m \to Y$ induced by the projection from the vertex $v$ of the cone $F$).

If $R_{\varphi_m}$ denotes the ramification divisor of $\varphi_m$ on $C_m$, by Riemann–Hurwitz (1.8) one has $O_{C_m}(R_{\varphi_m}) \cong O_{C_m}(K_{C_m} - \varphi_m(K_{C_1}))$. By adjunction formula, for $j = 1, m$, the canonical divisor $K_{C_j}$ is induced on $C_j$ by the divisor $K_S + C_j$ on $S$, which is
\[ K_S + C_j \sim (j-2)C_0 + (j-1)Ef + K_{C_f}, \quad j = 1, m. \]

Therefore one has
\[ O_{C_m}(R_{\varphi_m}) \cong O_{C_m}((m-1)C_1) \quad \text{and} \quad \deg R_{\varphi_m} = (m-1)C_1 \cdot C_m = m(m-1)C_1^2 = m(m-1)e. \] (2.10)

Using Riemann–Hurwitz formula (1.8), one gets therefore
\[ 2g_m - 2 = m(2\gamma - 2) + m(m-1)e \]
which gives (2.8).

(v) Since $\deg X_m = me$, then $\deg O_{X_m}(j) = jme$ whereas, from above, $\deg \omega_{X_m} = 2g_m - 2 = 2m(\gamma - 1) + m(m-1)e$. Since $e \geq 2\gamma - 1$, it is a straightforward computation to notice that if $j \geq m$ then
\[ \deg O_{X_m}(j) \geq \deg \omega_{X_m}, \]
which implies the non-speciality of $O_{X_m}(j)$ for any $j \geq m$. The computation of $h^0(X_m, O_{X_m}(j))$ then reduces to simply apply Riemann–Roch on the curve $X_m$. \qed
Lemma 2.6. Let $Z \subset \mathbb{P}^R$ be a non-degenerate, connected, projective curve, which is possibly reducible and which has at most nodes as possible singularities. Let $D = \text{Sing}(Z)$ denote its scheme of nodes, whose cardinality we denote by $\delta$ (in particular $\delta = 0$ and $D = \emptyset$ if e.g. $Z$ smooth and irreducible). Let $H$ be a hyperplane in $\mathbb{P}^R$ and $v \in \mathbb{P}^R \setminus (H \cup Z)$ be a point. Assume that the projection $\pi_v : Z \to H \cong \mathbb{P}^{R-1}$ from the point $v$ is such that $Y := \pi_v(Z) \subset H$ is smooth and irreducible. Let $R_{\pi_v}$ be the ramification divisor of $\pi_v$.

Then $R_{\pi_v}$ is a Cartier divisor on $Z$ and the following exact sequence holds
\begin{equation}
0 \to \mathcal{L}_Z \to N_{Z/\mathbb{P}^R} \to \pi_v^*(N_{Y/\mathbb{P}^{R-1}}) \to 0, \tag{2.11}
\end{equation}
where $N_{Z/\mathbb{P}^R}$ denotes the normal sheaf of $Z$, which is locally free on $Z$, and $\mathcal{L}_Z$ is a line bundle on $Z$ such that
\[
\deg \mathcal{L}_Z = \deg Z + \deg R_{\pi_v} + \delta.
\]

If, in particular, $Z = X_m$ as in Proposition 2.8, for some $m \geq 2$, and $v$ is the vertex of the cone $F = F_Y$ then $\pi_v(X_m) = Y$, where $Y$ a hyperplane section of $F$ not passing through $v$ as in Proposition 2.8 and (2.11) reads
\begin{equation}
0 \to \mathcal{O}_{X_m}(R_{\pi_v}) \otimes \mathcal{O}_{X_m}(1) \to N_{X_m/\mathbb{P}^R} \to \pi_v^*(N_{Y/\mathbb{P}^{R-1}}) \to 0. \tag{2.12}
\end{equation}

Proof. If $\mathcal{I}_{Z/\mathbb{P}^R}$ denotes the ideal sheaf of $Z$ in $\mathbb{P}^R$ then, since $Z$ is at most nodal, $N_{Z/\mathbb{P}^R} := \text{Hom}(\mathcal{I}_{Z/\mathbb{P}^R}, \mathcal{O}_Z)$ and $T_{\mathbb{P}^R}|_{Z} := \text{Hom}(\mathcal{O}_Z^1, \mathcal{O}_Z)$ are both locally–free of rank $R-1$ and $R$, respectively (cf. [38, page 30]).

If we take into account the projection $\pi_v : Z \to Y \subset H$, one has $\pi_v^*(\mathcal{O}_Y) \cong \mathcal{O}_Z$ and $\pi_v^*(\mathcal{O}_Y(1)) \cong \mathcal{O}_Z(1)$; thus, considering the Euler sequences of $Z$ and $Y$,
\[
0 \to \mathcal{O}_Z \to \mathcal{O}_Z(1)^{\oplus (R+1)} \to T_{\mathbb{P}^R}|_Z \to 0
\]
\[
0 \to \mathcal{O}_Y \to \mathcal{O}_Y(1)^{\oplus R} \to T_{\mathbb{P}^{R-1}}|_Y \to 0
\]
and pulling–back to $Z$ via $\pi_v$ the second Euler sequence, one deduces the following exact diagram

\[
\begin{array}{ccc}
0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow \\
0 & \mathcal{O}_Z(1) & \text{Ker } \alpha \\
\downarrow & \downarrow & \downarrow \\
0 & \mathcal{O}_Z & \mathcal{O}_Z(1)^{\oplus (R+1)} \\
\downarrow & \downarrow & \downarrow \\
0 & \mathcal{O}_Z & \mathcal{O}_Z(1)^{\oplus R} & \pi_v^*(T_{\mathbb{P}^{R-1}}|_Y) & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
0 & 0 & 0 & 0 & 0
\end{array}
\]
where the map $\alpha$ is surjective by the Snake Lemma. The exactness of the diagram implies that $\text{Ker } \alpha \cong \mathcal{O}_Z(1)$. Hence, from the right–most exact column of the diagram, we get
\begin{equation}
0 \to \mathcal{O}_Z(1) \to T_{\mathbb{P}^R}|_Z \to \pi_v^*(T_{\mathbb{P}^{R-1}}|_Y) \to 0. \tag{2.13}
\end{equation}

If we set $\Omega^1_Z$ the cotangent sheaf (or the sheaf of Kähler differentials) on $Z$, then its dual $\Theta_Z := \mathcal{Hom}(\Omega^1_Z, \mathcal{O}_Z)$ is not locally–free, but it is torsion free (cf. [38]) and it is called the sheaf of derivations of $\mathcal{O}_Z$ (when $Z$ is smooth and irreducible, $\Omega^1_Z$ coincides with the canonical bundle whereas $\Theta_Z$ with the tangent bundle). At last, $T^1_Z := \mathcal{Ext}^1(\Omega^1_Z, \mathcal{O}_Z)$ is called the first cotangent sheaf of $Z$, which is a torsion sheaf supported on $\text{Sing}(Z)$. Since by assumption $Z$ is at most nodal, it is either $T^1_Z = 0$ (i.e. the zero–sheaf) when $Z$ is smooth, or $T^1_Z \cong \mathcal{O}_D$, where $D$ the set of nodes of $Z$, otherwise. By [38, page 30, (1.2)], one has the exact sequence
\begin{equation}
0 \to \Theta_Z \to T_{\mathbb{P}^R}|_Z \to N_{Z/\mathbb{P}^R} \to T^1_Z \to 0. \tag{2.14}
\end{equation}
Putting together (2.13) and (2.14) and taking into account the map \( \pi_v: Z \to Y \), one gets the following exact diagram:

\[
\begin{array}{cccccc}
0 & 0 & 0 & 0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \\
Ker \pi_{v*} & \mathcal{O}_Z(1) & Ker \beta & \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
0 & T_{P^R|Z} & N_{Z/P^R} & T^1_Z & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
\pi_{v*} & \pi^*(T_{P^R|Z}) & \pi^*(N_{Z/P^R}) & \pi^*(T^1_Z) & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
Coker \pi_{v*} & 0 & 0 & 0 & \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
0 & 0 & 0 & 0 & \\
\end{array}
\]

where \( \beta \) is defined by the diagram. From \([38]\), the sequence (2.14) splits into two exact sequences

\[
\begin{align*}
0 & \to \Theta_Z \to T_{P^R|Z} \to N'_Z \to 0 \\
0 & \to N'_Z \to N_{Z/P^R} \to T_Z^1 \to 0,
\end{align*}
\]

where \( N'_Z \) is the equi–singular sheaf. Hence, the previous exact diagram gives rise to the following:

\[
\begin{array}{cccccc}
0 & 0 & 0 & 0 & 0 & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \\
Ker \pi_{v*} & \mathcal{O}_Z(1) & Ker \beta' & \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
0 & T_{P^R|Z} & N'_Z & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
\pi_{v*} & \pi^*(T_{P^R|Z}) & \pi^*(N'_Z) & 0 \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
Coker \pi_{v*} & 0 & 0 & 0 & \\
\downarrow & \downarrow & \downarrow & \downarrow & \\
0 & 0 & 0 & 0 & \\
\end{array}
\]

where \( \beta' \) is induced by \( \beta \) from the previous diagram. By the Snake Lemma, one has therefore

\[
0 \to Ker \pi_{v*} \to \mathcal{O}_Z(1) \to Ker \beta' \to Coker \pi_{v*} \to 0. \tag{2.16}
\]

Since \( \pi^*(TY) \) is a line bundle on \( Z \) and \( \Theta_Z \) has generically rank 1 on \( Z \), if it were \( Ker \pi_{v*} \neq 0 \) then it would be a torsion sheaf, which is a contradiction by (2.16) and the fact that \( \mathcal{O}_Z(1) \) is a line bundle on \( Z \). Therefore (2.16) gives

\[
0 \to \mathcal{O}_Z(1) \to Ker \beta' \to Coker \pi_{v*} \to 0. \tag{2.17}
\]

Since by the right–most column of diagram (2.15) the sheaf \( Ker \beta' \) has generically rank 1 and, by the left–most column of diagram (2.15), \( Coker \pi_{v*} \) is a torsion sheaf, from (2.17) it follows that \( Ker \beta' \) is a line bundle whereas \( Coker \pi_{v*} \cong \mathcal{O}_{R_{\pi_v}} \), and \( R_{\pi_v} \) is the (effective, Cartier) ramification divisor of the projection \( \pi_v \). Thus, \( Ker \beta' \) is a line bundle on \( Z \) such that, from (2.17), is isomorphic to \( \mathcal{O}_Z(R_{\pi_v}) \otimes \mathcal{O}_Z(1) \). Therefore, the sequence (2.17) reads as

\[
0 \to \mathcal{O}_Z(1) \to \mathcal{O}_Z(R_{\pi_v}) \otimes \mathcal{O}_Z(1) \to \mathcal{O}_{R_{\pi_v}} \to 0. \tag{2.18}
\]
From diagram (2.10) we deduce

\[
\begin{array}{cccccc}
0 & 0 & 0 & \downarrow & \downarrow & \downarrow \\
0 & \mathcal{O}_Z(R_{\pi_e}) \otimes \mathcal{O}_Z(1) & \mathcal{O}_D & \mathcal{O}_D & \mathcal{O}_D & 0 \\
0 & N'_Z & T'^1_Z \cong \mathcal{O}_D & 0 & 0 & 0 \\
0 & \pi_v^*(N_{Y/P^R}) & \pi_v^*(N_{Y/P^R}) & 0 & 0 & 0 \\
0 & 0 & 0 & & & \\
\end{array}
\]

By the Snake Lemma again, $\text{Ker } \beta =: \mathcal{L}_Z$ is a line bundle too, for which

\[0 \to \mathcal{O}_Z(R_{\pi_e}) \otimes \mathcal{O}_Z(1) \to \mathcal{L}_Z \to T'^1_Z \cong \mathcal{O}_D \to 0. \tag{2.19}\]

holds. In particular, by (2.19) one has

\[\deg \mathcal{L}_Z = \deg (\mathcal{O}_Z(R_{\pi_e}) \otimes \mathcal{O}_Z(1)) + \delta = \deg Z + \deg R_{\pi_e} + \delta\]

as stated. Moreover, from the middle–column of the above diagram, one also has

\[0 \to \mathcal{L}_Z \to N_{Z/P^R} \to \pi_v^*(N_{Y/P^R}) \to 0,\]

and this concludes the first part of the statement.

At last, if $Z = X_m \subset F$ as in Proposition 3.1 and if $v$ is the vertex of the cone $F$, the projection $\pi_v$ induces a $m$–sheeted ramified cover of the base curve $Y$ which is a hyperplane section of $F$ not passing through the vertex $v$; in this case $\delta = 0$, $D = 0$ and $\mathcal{L}_X \cong \mathcal{O}_X(R_{\pi_v}) \otimes \mathcal{O}_X(1)$ so (2.11) becomes (2.12), as stated. \qed

3. Superabundant components of Hilbert schemes

This section is entirely devoted to the construction of superabundant components of Hilbert schemes and to the proof of our Main Theorem. To do so, we will need to deal with the surjectivity of the Gaussian–Wahl map $\Phi_{\gamma, \mathcal{O}_Y}$ for $Y \subset \mathbb{P}^{R-1}$ as in §2.1 (cf. Claim 3.3 below).

Remark 3.1. Recall that $\mathcal{O}_Y(1) \cong \mathcal{O}_C(E)$ is of degree $e \geq 2\gamma - 1$. Taking into account numerical assumptions as in Proposition 1.4 for $6 \leq \gamma \leq 8$, the condition $2\gamma - 1 \geq \gamma + 12$ cannot hold since it would give $\gamma \geq 13$, contradicting that $6 \leq \gamma \leq 8$; similarly, condition $2\gamma - 1 \geq \gamma + 9$ does not hold for $\gamma = 9$. On the contrary, $\gamma \geq 10$ ensures that $\deg \mathcal{O}_C(E) = e \geq 2\gamma - 1 \geq \gamma + 9$ holds true so we can apply Proposition 1.4 to the pair $(C, \mathcal{O}_C(E))$ giving rise to $Y$ to prove the next result.

Proposition 3.2. Let $\gamma \geq 10$, $e \geq 2\gamma - 1$ and $R = e - \gamma + 1$ be integers. Let $\mathcal{I}_{e, \gamma, R-1}$ be the distinguished component of $\mathcal{I}_{e, \gamma, R-1}$ and let $[Y] \in \mathcal{I}_{e, \gamma, R-1}$ be general. Then:

(a) the Gaussian–Wahl map $\Phi_{\omega_Y, \mathcal{O}_Y}$ is surjective,

(b) $\mathcal{H}(\mathcal{I}_{e, \gamma, R-1})$ is generically smooth of dimension

\[\dim \mathcal{H}(\mathcal{I}_{e, \gamma, R-1}) = \lambda_{e, \gamma, R-1} + R = R(e + 1) - (R - 4)(\gamma - 1), \tag{3.1}\]

and

(c) the cone $F$, corresponding to $[F] \in \mathcal{H}(\mathcal{I}_{e, \gamma, R-1})$ general, is unobstructed in $\mathbb{P}^R$.

Proof. As observed in Remark 3.1 $\gamma \geq 10$ and $e \geq 2\gamma - 1$ imply that numerical assumptions of Proposition 1.4 certainly hold. Moreover, since the pair $(C, \mathcal{O}_C(E))$, giving rise to $Y$, is such that $C$ is with general moduli and $\mathcal{O}_C(E) \in \text{Pic}^c(C)$ is general we are in position to apply Propositions 1.4 and 1.5 from which (a), (b) and (c) directly follow. \qed
Notice that (3.1) coincides with the expression (2.7), which has been independently found via the parametric description of \( \mathcal{H}(\mathcal{I}_{e,\gamma,R}) \) in § 2.2.

From Remark 3.1 and Proposition 3.2, we therefore fix from now on the following numerical assumptions:

\[
\gamma \geq 10, \quad e \geq 2\gamma - 1, \quad R = e - \gamma + 1, \quad m \geq 2.
\] (3.2)

Furthermore, to ease notation, we simply pose:

\[
d := me, \quad X := X_m, \quad g := g_m,
\] (3.3)

where \( X_m \) and \( g_m \) are as in Proposition 2.5.

In this set–up we have that \([X] \in \mathcal{I}_{d,g,R} \); we now show that, as \([F] \) varies in \( \mathcal{H}(\mathcal{I}_{e,\gamma,R}) \), curves \( X \) fill–up an irreducible locus in \( \mathcal{I}_{d,g,R} \) as follows. With notation as in § 2.2 set first

\[
\mathcal{U}_{e,\gamma,R} := \left\{ u := ([C], \mathcal{O}_C(E), S, C_1) \mid [C] \in \mathcal{M}_\gamma \text{ general}, \mathcal{O}_C(E) \in \text{Pic}^e(C) \text{ general}, \mathfrak{F} = \mathcal{O}_C \oplus \mathcal{O}_C(-E), \ S = \mathbb{P}(\mathfrak{F}), \ C_1 \in |\mathcal{O}_S(C_0 + Ef)| \text{ general} \right\};
\]

by construction \( \mathcal{U}_{e,\gamma,R} \) is obviously irreducible. Then, for any \( m \geq 2 \), consider

\[
\mathcal{W}_{d,g,R} := \left\{ (u, C_m) \mid u \in \mathcal{U}_{e,\gamma,R}, \ C_m \in |\mathcal{O}_S(m(C_0 + Ef))| \text{ general} \right\} \xrightarrow{\pi} \mathcal{U}_{e,\gamma,R-1}, \ (u, C_m) \mapsto u,
\]

where the natural projection map \( \pi \) endows \( \mathcal{W}_{d,g,R} \) with a structure of a non–empty, open dense subset of a projective–bundle over \( \mathcal{U}_{e,\gamma,R} \); hence \( \mathcal{W}_{d,g,R} \) is irreducible too (recall that \( d = me \) and \( g = g_m \) depend on \( m \)).

By the very definition of \( \mathcal{W}_{d,g,R} \), one has a natural Hilbert morphism

\[
h : \mathcal{W}_{d,g,R} \rightarrow \mathcal{I}_{d,g,R}
\]

\[
(u, C_m) \mapsto [X_m] := [\Psi(C_m)],
\]

where \( \Psi \) the morphism as in Proposition 2.2, and one defines

\[
\mathcal{S}_{d,g,R} := h(\mathcal{W}_{d,g,R}) \subset \mathcal{I}_{d,g,R}.
\] (3.4)

**Lemma 3.3.** \( \mathcal{S}_{d,g,R} \) is irreducible, it has dimension

\[
\dim \mathcal{S}_{d,g,R} = \lambda_{d,g,R} + \sigma_{d,g,R},
\] (3.5)

where

\[
\lambda_{d,g,R} = (R + 1)me - (R - 3) (m(\gamma - 1) + \frac{m(m - 1)}{2} e)
\]

is the expected dimension of \( \mathcal{I}_{d,g,R} \) as in (1.3), whereas the positive integer

\[
\sigma_{d,g,r} := (R - 4) \left[ (\gamma - 1)(m(\gamma - 1) + e + \frac{m(m - 3)}{2} e) + 4(e + 1) + em(m - 5) \right]
\]

is called the superabundance summand of the dimension of \( \mathcal{S}_{d,g,R} \).

Furthermore, \( \mathcal{S}_{d,g,R} \) is generically smooth.

**Proof.** By construction of \( \mathcal{S}_{d,g,R} \), it is irreducible and

\[
\dim \mathcal{S}_{d,g,R} = \dim \mathcal{H}(\mathcal{I}_{e,\gamma,R-1}) + \dim |\mathcal{O}_F(m)|,
\]

where \([F] \in \mathcal{H}(\mathcal{I}_{e,\gamma,R-1}) \) is general. Thus, from (3.1) (equivalently, from (2.7)) and from Proposition 2.2(v), the latter reads

\[
\dim \mathcal{S}_{d,g,R} = R(e + 1) - (R - 4)(\gamma - 1) + \frac{m(m + 1)}{2} e - m(\gamma - 1) = \lambda_{e,\gamma,R-1} + R + \frac{m(m + 1)}{2} e - m(\gamma - 1).
\] (3.6)

Taking into account (1.3) which, in our notation, reads

\[
\lambda_{d,g,R} = (R + 1)me - (R - 3) (m(\gamma - 1) + \frac{m(m - 1)}{2} e),
\]

to prove the first part of the statement it suffices to showing that \( \dim \mathcal{S}_{d,g,R} - \lambda_{d,g,R} = \sigma_{d,g,r} \) and that the latter integer is positive.

To do so, observe that

\[
\dim \mathcal{S}_{d,g,R} - \lambda_{d,g,R} = R(e + 1) - (R - 4)(\gamma - 1) + \frac{m(m + 1)}{2} e - m(\gamma - 1) - \left[ (R + 1)me - (R - 3) \left(m(\gamma - 1) + \frac{m(m - 1)}{2} e\right) \right] =
\]
\[
= R \left( \gamma(m - 1) - m + 2 + e \right) + Re \frac{m(m - 3)}{2} - 4(\gamma - 1)(m - 1) - em(m - 1) = \\
= (R - 4) \left[ (\gamma - 1)(m - 1) + 1 + e + \frac{m(m - 3)}{2}e \right] + 4(e + 1) + em(m - 5).
\]

Notice that, since \( R = e - \gamma + 1, e \geq 2 \gamma - 1 \) and \( \gamma \geq 10 \), then \( R - 4 \geq 6 \); moreover, since \( m \geq 2 \), the summands in square–parentheses add–up to a positive integer: the statement is clear for \( m \geq 3 \), whereas for \( m = 2 \) one has \( (\gamma - 1)(m - 1) + 1 + e + \frac{m(m - 3)}{2}e = \gamma \geq 10 \). Concerning the summand \( 4(e + 1) \), in our assumptions it is \( 4(e + 1) \geq 8 \gamma \geq 80 \). The last summand \( em(m - 5) \) is non–negative for \( m \geq 5 \), whereas for \( m = 2, 3, 4 \) it is, respectively, \(-6e, -6e, -4e\); in all the latter three sporadic cases, the negativity of the summand \( em(m - 5) \) does not affect the positivity of the total expression.

The previous computations show that
\[
\dim S_{d,g,R} - \lambda_{d,g,R} = (R - 4) \left[ (\gamma - 1)(m - 1) + 1 + e + \frac{m(m - 3)}{2}e \right] + 4(e + 1) + em(m - 5) = \sigma_{d,g,R}
\]
and the first part of the statement is proved.

Concerning the generic smoothness of \( S_{d,g,R} \), we have first the following:

**Claim 3.4.** For \( [X] \in S_{d,g,R} \) general, one has
\[
h^0(X, N_{X/P}) = \lambda_{e, \gamma, R - 1} + h^0(Y, N_{Y/P,R - 1} \otimes \mathcal{T}_\phi) + \frac{m(m + 1)}{2}e - m(\gamma - 1),
\]
where \( \mathcal{T}_\phi \) is the Tschirnhausen bundle associated to the degree–\( m \) covering map \( \phi : X \to Y \) induced by the projection \( \pi_v \) from the vertex of the cone \( F \) as in diagram (2.5).

**Proof of Claim 3.4.** Consider the exact sequence (2.12) in Lemma 2.6 which, in the present notation, reads
\[
0 \to \mathcal{O}_X(R_{\pi_v}) \otimes \mathcal{O}_X(1) \to N_{X/P} \to \pi_v^*(N_{Y/P,R - 1}) \to 0.
\]
From Proposition 2.9 (iii), the degree–\( m \) covering map \( \phi : X \to Y \) is induced by the projection \( \pi_v \) from the vertex of the cone \( F \) and, by (2.10), we have \( \mathcal{O}_X(R_{\pi_v}) = \mathcal{O}_X(R_{\phi}) \cong \mathcal{O}_X(m - 1) \). Therefore, the previous exact sequence gives
\[
0 \to \mathcal{O}_X(m) \to N_{X/P} \to \phi^*(N_{Y/P,R - 1}) \to 0.
\]
From Proposition 2.9 (v), \( \mathcal{O}_X(m) \) is non–special on \( X \), so
\[
h^0(X, N_{X/P}) = h^0(X, \phi^*(N_{Y/P,R - 1})) + h^0(X, \mathcal{O}_X(m)).
\]
Since \( \phi \) is a finite morphism, using Leray’s isomorphism and projection formula, we get
\[
h^0(X, \phi^*(N_{Y/P,R - 1})) = h^0(Y, N_{Y/P,R - 1} \otimes \phi_* \mathcal{O}_X).
\]
Moreover, from §1.3 one has \( \phi_* \mathcal{O}_X = \mathcal{O}_Y \oplus \mathcal{T}_\phi \), where \( \mathcal{T}_\phi \) the Tschirnhausen bundle associated to \( \phi \). Thus,
\[
h^0(Y, N_{Y/P,R - 1} \otimes \phi_* \mathcal{O}_X) = h^0(Y, N_{Y/P,R - 1}) + h^0(Y, N_{Y/P,R - 1} \otimes \mathcal{T}_\phi).
\]
To sum–up, one has
\[
h^0(X, N_{X/P}) = h^0(Y, N_{Y/P,R - 1}) + h^0(Y, N_{Y/P,R - 1} \otimes \mathcal{T}_\phi) + h^0(X, \mathcal{O}_X(m)). \quad (3.7)
\]
By (2.9) with \( j = m \), one has
\[
h^0(X, \mathcal{O}_X(m)) = \frac{m(m + 1)}{2}e - m(\gamma - 1).
\]
From (1.3) and Corollary 1.3 it follows that
\[
h^0(Y, N_{Y/P,R - 1}) = \lambda_{e, \gamma, R - 1},
\]
since \( Y \) corresponds to a general point in the distinguished component \( \mathcal{I}_{e, \gamma, R - 1} \). \( \square \)

To conclude that \( S_{d,g,R} \) is generically smooth, we are left with the following:

**Claim 3.5.** For any \( m \geq 2 \), one has
\[
h^0(Y, N_{Y/P,R - 1} \otimes \mathcal{T}_\phi) = R. \quad (3.8)
\]
Proof of Claim 3.5. To prove the statement, we will use an inductive approach.

Assume first $m = 2$, so $X = X_2$ and $\varphi := \varphi_2 : X \to Y$ is the double cover of the curve $Y$, as in Proposition 2.5 (iii). In this case, the Tschirnhausen bundle $T_{\psi}^\vee$ is a line bundle on $Y$ which, from (1.7) and (2.10), equals $O_Y(-E) \cong O_Y(-1)$. Since $\gamma \geq 10$ and $e \geq 2\gamma - 1$, assumptions of Propositions 1.4 are satisfied. Therefore, from Proposition 1.5 (ii), we have $h^0(Y, N_{Y/P^{m-1}} \otimes O_Y(-1)) = R$ and (3.8) holds true in this case.

Take now $m \geq 3$ and assume that (3.8) holds for a degree $(m-1)$ covering map $\varphi := \varphi_{m-1} : X := X_{m-1} \to Y$, where $X_{m-1} \in |O_P(m-1)|$ general as in Proposition 2.5. To ease notation, the associated Tschirnhausen bundle $T_{\psi}^\vee$ on $Y$ will be simply denoted by $T_{m-1}^\vee$.

Let $Y' \in |O_P(1)|$ be general and consider the projective, connected, non-degenerate reducible curve $Z := X \cup Y' \subset F$ which, as a Cartier divisor on $F$, is such that $Z \in |O_P(m)|$. The singular locus of $Z$ is $D := X \cap Y'$ and consists of $\delta$ nodes, where $\delta := (m-1)H^2 = (m-1)e$, $H$ denoting the hyperplane section of $F$. As in §1.3 the curve $Z$ is endowed with a natural degree $m$ covering map $\psi : Z \to Y$, whose Tschirnhausen bundle $T_{\psi}^\vee$ on $Y$ will be simply denoted by $T_m^\vee$.

From Proposition 1.5 passing to duals, we get the exact sequence

$$0 \to O_Y(-D) \to T_m^\vee \to T_{m-1}^\vee \to 0$$

of vector bundles on $Y$. Tensoring this exact sequence with $N_{Y/P^{m-1}}$ gives

$$0 \to N_{Y/P^{m-1}} \otimes O_Y(-D) \to N_{Y/P^{m-1}} \otimes T_m^\vee \to N_{Y/P^{m-1}} \otimes T_{m-1}^\vee \to 0. \quad (3.9)$$

By induction, since $m-1 \geq 2$, one has $h^0(Y, N_{Y/P^{m-1}} \otimes T_{m-1}^\vee) = R$. Moreover, since $D$ is cut–out on the irreducible component $Y'$ by a hypersurface of degree $m-1$ in $\mathbb{P}^r$ and since $Y' \cong Y$, then $O_Y(D) \cong O_Y(m-1)$ and one has

$$h^0(Y, N_{Y/P^{m-1}} \otimes O_Y(-D)) = h^0(Y, N_{Y/P^{m-1}} \otimes O_Y(-(m-1))) = 0,$n

as it follows from Proposition 1.5 (iii) and from the fact that $m-1 \geq 2$.

By (3.9), we deduce that $H^0(Y, N_{Y/P^{m-1}} \otimes T_m^\vee)$ injects into $H^0(Y, N_{Y/P^{m-1}} \otimes T_{m-1}^\vee)$, so in particular

$$h^0(Y, N_{Y/P^{m-1}} \otimes T_m^\vee) \leq R. \quad (3.10)$$

On the other hand since $|Z| \in \mathfrak{R}_{d,g,R}$, where $\mathfrak{R}_{d,g,R}$ denotes the closure in $\mathcal{I}_{d,g,R}$ of $\mathcal{S}_{d,g,R}$, by (1.2) one must have

$$h^0(Z, N_{Z/P^n}) = \dim T_{|Z|}(\mathcal{I}_{d,g,R}) \geq \dim \mathcal{S}_{d,g,R} = \lambda_{e,\gamma,R-1} + R + \frac{m(m+1)}{2}e - m(\gamma-1), \quad (3.11)$$

as it follows from (3.8). Since $Z$ satisfies assumptions as in Lemma 2.6, we can consider the exact sequence (2.11). The line bundle $L_Z$ therein has degree

$$\deg L_Z = \deg Z + \deg R_\psi + \delta = me + \deg R_\psi + (m-1)e.$$n

By definition of $\psi : Z \to Y$, the ramification of this map is supported on the irreducible component $X = X_{m-1}$ of $Z$, namely $R_\psi = R_{\varphi_{m-1}}$ where $\varphi_{m-1} : X \to Y$. From (2.10) we therefore have $\deg R_{\varphi_{m-1}} = (m-1)^2e$, so

$$\deg L_Z = me + (m-1)^2e + (m-1)e = m^2e.$$n

Hence, $L_Z$ is a non–special line bundle on $Z$, $Z$ being a reduced, connected and nodal curve of arithmetic genus $p_a(Z) = g = g_m$ as in (2.8) (the non–speciality of $L_Z$ can be proved by applying the same numerical computation as in the proof of Proposition 2.5 (v), replacing the canonical bundle with the dualizing sheaf $\omega_Z$). Thus, from (2.11) one gets

$$h^0(Z, N_{Z/P^n}) = h^0(Z, \psi^*(N_{Y/P^{m-1}})) + h^0(Z, L_Z) \quad \text{where}$$

$$h^0(Z, L_Z) = \chi(Z, L_Z) = \frac{m(m+1)}{2}e - m(\gamma-1),$$

both equality following from the non–speciality of $L_Z$. As for the summand $h^0(Z, \psi^*(N_{Y/P^{m-1}}))$, we can apply projection formula and Leray’s isomorphism, which gives

$$h^0(Z, \psi^*(N_{Y/P^{m-1}})) = h^0(Y, N_{Y/P^{m-1}}) + h^0(Y, N_{Y/P^{m-1}} \otimes T_m^\vee).$$

Since $h^0(Y, N_{Y/P^{m-1}}) = \lambda_{e,\gamma,R-1}$ as $[Y] \in \mathcal{I}_{e,\gamma,R-1}$ is general (cf. Corollary 1.5), then comparing with (3.11) we deduce that $h^0(Y, N_{Y/P^{m-1}} \otimes T_m^\vee) \geq R$. Thus, using the previous inequality (3.10), we get $h^0(Y, N_{Y/P^{m-1}} \otimes T_m^\vee) = R$. 

By semi–continuity on the general element \([X_m] \in S_{d,g,R}\), with its degree–m covering map \(\varphi_m : X_m \to Y\) and its associated Tschirnhausen bundle \(T_{\varphi_m}^{\nu}\), we deduce that
\[
h^0(Y, N_{Y/B-R} \otimes T_{\varphi_m}^{\nu}) \leq R.
\]
On the other hand, replacing \(Z\) with \(X_m\) in the previous computations, since
\[
h^0(X_m, N_{X_m/B^m}) = \dim T_{[X_m]}(I_{d,g,R}) \geq \dim S_{d,g,R} = \lambda_{d,g,R} + R + \frac{m(m + 1)}{2} - m(g - 1),
\]
one can conclude by applying (2.12), with \(O_{X_m}(R_{\varphi_m}) \cong O_{X_m}(m - 1)\) as in (2.10), and reasoning as we did for \(Z\) above.

The previous computations show that, for \([X] \in S_{d,g,R}\) general, one has
\[
\dim S_{d,g,R} = \lambda_{d,g,R} + \sigma_{d,g,R} = \dim T_{[X]}(S_{d,g,R}) = T_{[X]}(I_{d,g,R}),
\]
which therefore implies that \(S_{d,g,R}\) is generically smooth.

We are finally in position to prove our Main Theorem.

**Proof of Main Theorem.** The first part of Lemma 3.3 ensures that any irreducible component of \(I_{d,g,R}\) containing \(S_{d,g,R}\) has to be superabundant, having dimension at least \(\dim S_{d,g,R} = \lambda_{d,g,R} + \sigma_{d,g,R}\). On the other hand, the proofs of Claims 3.4 and 3.5 show that \(S_{d,g,R}\) is contained in a unique component of \(I_{d,g,R}\), more precisely it fills–up an open, dense subset of an irreducible component of \(I_{d,g,R}\) which is generically smooth, superabundant, of dimension \(\lambda_{d,g,R} + \sigma_{d,g,R}\). Indeed, by (3.12), for \([X] \in S_{d,g,R}\) general we have that
\[
\dim T_{[X]}(S_{d,g,R}) = h^0(X, N_{X/B^m}) = \dim T_{[X]}(I_{d,g,R}) = \dim S_{d,g,R} = \lambda_{d,g,R} + \sigma_{d,g,R}.
\]

**Remark 3.6.** It is clear from the construction that \(S_{d,g,R}\) lies in a component of \(I_{d,g,R}\) which cannot dominate \(\mathcal{M}_g\). Indeed, the modular morphism of such a component maps to the Hurwitz space \(H_{e,g,m}\) parametrizing isomorphism classes of genus–\(g\) curves arising as \(m\)-sheeted, ramified covers of irrational curves of genus \(\gamma\).
