(Dated: May 31, 2021)

We investigate the possibility of obtaining chimera state solutions of the non-local Complex Ginzburg-Landau Equation (NLCGLE) in the strong coupling limit when it is important to retain amplitude variations. Our numerical studies reveal the existence of a variety of amplitude mediated chimera states (including stationary and non-stationary two cluster chimera states), that display intermittent emergence and decay of amplitude dips in their phase incoherent regions. The existence regions of the single-cluster chimera state and both types of two cluster chimera states are mapped numerically in the parameter space of $C_1$ and $C_2$ the linear and nonlinear dispersion coefficients respectively of the NLCGLE. They represent a new domain of dynamical behaviour in the well explored rich phase diagram of this system. The amplitude mediated chimera states may find useful applications in understanding spatio-temporal patterns found in fluid flow experiments and other strongly coupled systems.

PACS numbers: 05.45.Ra, 05.45.Xt, 89.75.-k

Chimera states, spatio-temporal patterns of co-existing coherent and incoherent behaviour in an array of coupled identical oscillators, have received a great deal of attention in recent times [1, 2]. First found by Kuramoto and Battogtakh [3] from numerical investigations of the weak coupling version of the non-local Complex Ginzburg-Landau Equation (NLCGLE), the chimera state has subsequently been studied for a variety of systems [7–26] including two dimensional ones [24, 27–29] and those that have time-delayed coupling [30] or those with a time-delayed feedback [31]. The phase only chimera state has been suggested as a useful paradigm to represent such curious phenomenon as unihemispheric sleep in certain mammals and birds, where during sleep one half of their brain is quiescent while the other half remains active [3, 32]. Recently the phase only chimera states have also been observed experimentally in a chemical system [33], in an opto-electronic set up [34] under controlled laboratory settings as well as in a mechanical experiment consisting of two populations of metronomes [35]. An experimental realization of a modified Ikeda time-delayed equation is also shown to exhibit chimera-like states [36]. These past studies have however been confined to the weak coupling limit of the oscillator arrays where the amplitude variations have been ignored and only the dynamical behaviour of the phases have been considered. In many practical situations, such as in fluid flow representations, amplitude equations provide a more realistic description of the physical phenomena and have been widely employed to study the collective behaviour of such systems. An interesting question to ask is therefore whether spatio-temporal patterns corresponding to chimera states can exist for the strong coupling limit. We note here that recently, multi-chimera states have been found in networks of coupled FitzHugh-Nagumo (FHN) and Hindmarsh-Rose (HR) neuron models [37, 38]. In this paper we address the question of the existence of chimera states in strong coupling limits. We report the numerical discovery of chimera solutions for the NLCGLE equation in the regime where amplitude effects matter. In contrast to the classical chimera states found for the phase only systems, the present ones display amplitude activity in the incoherent region of the solution in the form of intermittent emergence and decay of amplitude dips and we classify them as amplitude mediated chimeras (AMCs). The phases of the oscillators in the incoherent region continue to have a random distribution. These states bear a close resemblance to the simultaneous appearance of laminar and turbulent regions in Couette flow studies [39, 40] and may have wider applications to other strongly coupled systems.

Our model system is the well known one dimensional NLCGLE [41] that has been extensively studied in the past in the context of applications to various physical, chemical and biological phenomena [12, 44].

$$\frac{\partial W}{\partial t} = W - (1 + iC_2)|W|^2W + K(1 + iC_1)(\mathbf{W} - W)$$  \hspace{1cm} (1)

where $W(x, t) = A(x, t)e^{i\phi(x, t)}$ is a complex field quantity with $A(x, t)$ and $\phi(x, t)$ representing the amplitude and phase respectively. $C_1$, $C_2$ and $K$ are real constants characterizing the linear and the non-linear dispersion and the coupling strength respectively. The non-local mean field $\mathbf{W}(x, t)$ is given by

$$\mathbf{W}(x, t) = \int_{-1}^{1} G(x - x')W(x - x', t)dx'$$  \hspace{1cm} (2)

where the normalized coupling kernel $G(x - x')$ has an

*e-mail: gautam.sethia@gmail.com
exponentially decaying form, namely,
\[ G(x) = \frac{\kappa}{2(1 - e^{-\kappa|x|})} e^{-\kappa|x|} \]  
with $\kappa > 0$. $\kappa$ is the inverse of the coupling range and provides a measure of the non-locality of the coupling. The space coordinate is made dimensionless by normalizing it with the system length $L$ and hence the system size extends from $-1$ to 1. For $K \ll 1$, Eq. (1) can be reduced to a non-local evolution equation for the phase function $\phi(x,t)$ that has been the subject of several past studies for the classical chimera solutions. We have carried out extensive numerical explorations to seek chimera solutions of Eq. (1) and have discovered a variety of such states over a wide range of parameter space. Broadly they consist of stationary one cluster and two cluster chimera states and also a non-stationary (breather) variety of the two cluster state. The two coherent regions of the two cluster chimera states have opposite phases and are separated by incoherent regions. Multi-cluster phase coherent regions have also been observed before in time delayed systems [30] and more recently by Zhu et al. [31, 40] in the weak coupling limit of the NLCGLE. The major difference of the present solutions from their counterparts of the phase only systems is that these amplitude mediated chimera states have significant temporal variations of the amplitude in the incoherent spatial regions. These regions show intermittent emergence and decay of amplitude dips which in some cases can resemble amplitude hole (defect) solutions.

In looking for chimera states, our choice of the system parameters has been guided by earlier investigations of the NLCGLE including those in the weak coupling limit. Thus we have chosen two values of $K$, namely 0.05 and 0.4 to represent weak and strong coupling cases respectively. The value of $\kappa$ has been chosen to be equal to 2 so that $\kappa L = 4$ which is the same as chosen by Kuramoto and Battogtokh [4] (who had $\kappa = 4$ and $L = 1$). The values of $C_1$ and $C_2$ have been varied over a wide range. In Fig. 1 we show a typical snapshot of the amplitude mediated one cluster and two cluster solutions in panels (a) and (b) respectively whereas in panel (c) for comparison we display a classical phase only chimera obtained in this case from Eq. (1) in the weak coupling limit by taking a low value of $K$. Notice that for the classical chimera state the amplitude fluctuations are negligible, justifying their neglect in the weakly coupled limit of the NLCGLE. For the classical (phase only) chimera the set of values $C_1 = -0.9$ and $C_2 = 1$ corresponds to $\alpha = \tan^{-1}(C_2 - C_1)/(1 + C_1 C_2) = 1.52$ where $\alpha$ is the phase-shift parameter in the weak coupling limit [4]. For the AMCs the amplitude variations in the incoherent region are quite significant, sometimes dipping close to zero values corresponding to traveling hole like solutions. Our simulations have been done with the XPPAUT [47] package with 201 discrete oscillators equally spaced on a ring.

We have carefully checked our numerical results to rule out finite size effects. The nature of the AMC is found not to change when, for example, we change the number of oscillators from 201 to 401. The characteristics of the AMC remain the same and it does not exhibit any transient nature or tendency to collapse. The initial conditions of our simulations consist of slightly perturbed

FIG. 1: (Color online) Snapshots of the stationary state spatial profiles of the phase ($\phi$) and the amplitude $|W|$ (multiplied by 10 and shown in blue, the upper curves) for (a) a single cluster AMC with $K = 0.40, C_1 = -0.5$, $C_2 = 2.0$; (b) a 2-cluster AMC with $K = 0.40, C_1 = -4.0$, $C_2 = 0.5$; and (c) a phase-only chimera with $K = 0.05$, $C_1 = -0.9$, $C_2 = 1.0$ respectively. $\kappa$ is fixed at 2 for all the cases. Panels (d – f) show the corresponding spatial profiles of the long-time average of the order parameter amplitudes ($R$) and the frequencies ($\omega = <\phi>$). The computed value of $\Delta$ is marked with a horizontal dashed line (in black). The vertical dotted lines in the lower three panels (d – f) are drawn as a visual guidance to the coherent segments.
uniformly spaced phases from 0 to $2\pi$ with unit amplitude.

The stationary patterns of these AMCs can also be understood in terms of a complex order parameter defined as,

$$R(x,t)e^{i\theta(x,t)} = \int_{-1}^{1} G(x-x')A(x-x',t)e^{i\theta(x-x',t)}dx'$$

(4)

where $R(x,t)$ is the amplitude of the order parameter, $\Theta(x,t)$ is the mean phase and $\theta = \phi + \Omega t$ is the relative phase defined in the frame rotating with the angular frequency $\Omega$ and amplitude $A$ of the coherent segment of the chimera. Using Eq.(4), and separating Eq.(4) into its real and imaginary parts, one can get,

$$\frac{\partial A}{\partial t} = (1-K-A^2)A$$

$$+KR\cos(\Theta-\theta) - KR C_1 \sin(\Theta - \theta)$$

$$A \frac{\partial \theta}{\partial t} = -(-\Omega + KC_1 + C_2 A^2)A$$

$$+KR C_1 \cos(\Theta - \theta) + KR \sin(\Theta - \theta)$$

(5)

By restricting to time stationary solutions, we get:

$$\cos(\Theta - \theta) = \left[1 + \left(1 + C_1 C_2\right)A^2 - (1 + C_1 \Omega)\right] \left(\frac{A}{R(x)}\right)$$

(6)

The absolute value of the right hand side of Eq.(6) cannot be greater than 1 and this puts a condition on the magnitude $R$ of the order parameter, namely $(R(x) \geq |\Delta|)$ in any coherent segment in space where

$$\Delta = \left[1 + \left(1 + C_1 C_2\right)A^2 - (1 + C_1 \Omega)\right] A$$

(7)

We obtain the amplitude $A$ and the frequency $\Omega$ of the coherent segment from the simulations and compute the value of $\Delta$ using Eq.(7). In Fig(II)-d)-(f) we have plotted the time averaged profiles of $R(x)$ for the chimera states corresponding to the snapshots in Fig(II)-a)-(c) respectively. The horizontal line in each figure marks the computed $\Delta$ value. As can be seen the results are in good agreement in that the coherent segments found in Fig(II) correspond to regions where the condition $R > \Delta$ is satisfied. As a further check on the nature of the collective state we have also plotted the average frequency profiles in Fig(II) (d)-(f) which all show the typical signature of chimera states, namely a constant frequency in the coherent region (flat profile) and a peaked profile in the incoherent region [4]. For the non-stationary breather state the order parameter is no longer a constant quantity but shows a periodic temporal variation. This along with amplitude $|W|$ for any one of the oscillators is shown in Fig(II)-a) for the 2-cluster AMC state. Fig(II-b) shows the spatio-temporal pattern of the phase $\phi$ after the transients. Each oscillator goes through coherent and incoherent segments periodically.

To get a perspective of the existence regions of the AMCs with respect to other collective states of the NL-CGLE, we have next carried out a linear stability analysis of plane wave solutions of Eq.(II). that are of the form, $W_k^0(x,t) = a_k e^{i(\pi k x - \omega_k t)}$ and that satisfy the dispersion relation,

$$\omega_k = C_1(1 - a_k^2) + C_2 a_k^2$$

(8)

with $a_k^2 = 1 - K', K' = K(1 - I_{k,k})$ and

$$I_{k,k} = \int_{-1}^{1} G(x')e^{i\pi k x'} dx'$$

Perturbing these equilibrium solutions by writing $W_k = [1 + u(x,t)]W_k^0$, where $u(x,t) = \sum_n u_n(t)e^{i\pi k x}$ and substituting in the linearized form of Eq.(II), we can get a variational equation for $u_n$,

$$\frac{\partial u_n}{\partial t} = [1 + i \omega_k - 2(1 + i C_2) a_k^2 + K(1 + i C_1)] u_n - (1 + i C_2) a_k^2 \bar{u}_n$$

(9)

Taking $u_n(t) \sim e^{\lambda t}$, Eq.(9) and its complex conjugate yield a $2 \times 2$ matrix $M$, whose eigenvalues are determined from the following quadratic characteristic equation [4],

$$|M - \lambda I| \equiv \lambda^2 + (r_1 + i r_2) \lambda + p_1 + ip_2 = 0$$

(10)
where $I$ is the $2 \times 2$ unit matrix and $r_1 = -(a + e), r_2 = -(b + f), p_1 = -bf + ac - c^2 - d^2$ and $p_2 = af + be$, which in turn are expressed in terms of system parameters:

$$
\begin{align*}
a &= 1 - 2a_k^2 + K I_{k,n+k} - K \\
b &= \omega_k - 2C_2a_k^2 + KC_1(I_{k,n+k} - 1) \\
c &= -a_k^2 \\
d &= -C_2a_k^2 \\
e &= 1 - 2a_k^2 + K I_{k,n-k} - K \\
f &= -\omega_k + 2C_2a_k^2 - KC_1(I_{k,n-k} - 1).
\end{align*}
$$

Eq. (10) determines the eigenvalues $\lambda$ for a perturbation with a wave number $n$. Setting the real part of $\lambda$ to be zero gives us a condition for marginal stability of the form $\Phi(\kappa, k, n) = 0$, where

$$
\Phi(\kappa, k, n) = -p_2^2 + r_1 r_2 p_2 + r_1^2 p_1
$$

(12)

From our numerical analysis we find that the lowest mode number perturbation ($n = 1$) is the first one to get destabilized and therefore determines the marginal stability curve. We fix $n = 1$ for our further stability analysis. For the uniform ($k = 0$) state, we are able to get a simple analytic form for the marginal stability curve, namely,

$$
\Phi(\kappa, 0, 1) = 1 + C_1 C_2 + \frac{K(1 + C_2^2)}{2}(1 - \gamma) = 0
$$

(13)

where $\gamma \equiv I_{0,1} = \frac{\kappa^2 \coth(\kappa)}{\pi^2 + \kappa^2}$ accounts for the non-locality in the system.

The stability condition $\Phi > 0$ reduces to the well known Benjamin-Feir-Newell criterion $1 + C_1 C_2 > 0$ for $\gamma \to 1$ corresponding to large $\kappa$ i.e. local or diffusive coupling and in the global limit ($\gamma \to 0$ for small $\kappa$), to that reported in earlier works [49, 50]. Fig. (a) shows the stability diagram for the uniform state ($k = 0$) as well as for the $k = 1$ traveling wave state in the $C_1 - K$ phase space where $C_2$ is fixed at 1 and $\kappa$ at 2. The phase only models are valid near the dotted line at $K = 0$. Similarly Fig. (b), (c) show the stability diagrams in $C_1 - C_2$ phase space for two different values of $K$ but the same value of $\kappa$. The location of a few chimera states are marked by different point symbols (filled and open circles) on these stability diagrams. The open circles in Fig. (b) represent phase only chimera states that are found in the weak coupling limit. The filled circle marks the chimera state shown in Fig. (c). It is seen that the phase only chimera states co-exist with the stable uniform traveling wave state ($k = 0$) as has been noted earlier [2]. The AMCs on the other hand can exist in both the stable and unstable region of the $k = 0$ state. To determine the existence domain of the AMCs we have carried out a systematic and extensive numerical exploration in the $C_1 - C_2$ phase space. Our results are shown in Fig. (c) where the existence domains are marked in color. Single cluster AMCs are found in the region marked yellow (upper shaded region) and the two cluster and breather AMCs exist in the region marked in green (lower shaded region in bistable domain B). These domains thus mark a new dynamical region for the NLCGLE representing an additional collective excitation state of the system.

In conclusion, we have studied the NLCGLE system in the strong coupling limit and found a new class of chimera states where the incoherent regions display significant amplitude fluctuations. These amplitude mediated chimeras can be of the stationary kind (with a single or two cluster configuration of coherent regions) or have
an oscillatory nature. Our detailed numerical investigation have also marked out the existence regions of these hybrid states in the reference frame of the stability diagram of the uniform state and the k = 1 traveling wave state of the NLCGLE. These states not only complement the previously found phase only chimera states but also extend the applicability domain of such hybrid states to physical systems that are better represented by full blown amplitude equations such as the NLCGLE. Some systems that come to mind in this context are fluid flow simulations/experiments where the simultaneous appearance of laminar and turbulent regions have been observed\(^{39}\) and neuronal networks displaying bump states where a subset of neurons fire in synchrony while others fire incoherently\(^{51}\). The discovery of these novel states also opens up a number of interesting future areas of investigation including a study of their stability, delineating their linkages to other coherent solutions of the NLCGLE such as traveling waves and holes and exploring their existence for other forms of the coupling kernel.

GCS acknowledges the support of MPI-PKS, Dresden, Germany, where part of the work was carried out.
