Portfolio Theory and Risk Analysis Using Coefficient of Variation:

An Alternative to Mean-Variance Analysis

Julius O. Campeciño

Michigan State University, East Lansing, MI

Abstract

We presented here a direct calculation of risk from the coefficient of variation (CV) using an equation that has been derived here for the first time. We also presented a method to generate a stock CV that strongly correlates with performance. Consequently, we found that the price growths of stocks with low CV are approximately exponential which explains our finding here that the average total return of stocks with $0 \leq CV \leq 2$ between Dec 2008-2018 outperformed the average return of stocks with $CV > 2$ and $CV > 4$ by more than 300% and 400%, respectively. From these observations, we posit that minimizing CV does not only minimize risk but also maximizes returns, an observation that certainly goes against the high risk/high reward notion in modern finance as espoused in the mean-variance analysis, also known as the Modern Portfolio Theory.
Conflict of Interest Disclosure Statement

I have nothing to disclose.
I. Introduction

The 1950s saw the development of the mean-variance analysis also known as the Modern Portfolio Theory (MPT) which is still used today for optimizing security returns while minimizing risk (Markowitz (1952)). The method defined standard deviation (and variance) as the measure of risk which can be mathematically defined for a portfolio with \( n \) securities as:

\[
\sigma_P^2 = \sum_{i=1}^{n} w_i^2 \sigma_i^2 + \sum_{i=1}^{n} \sum_{j=1}^{n} 2w_i w_j \rho_{i,j} \sigma_i \sigma_j \quad j \neq i \quad Eq. 1
\]

where \( \sigma_i^2 \) and \( \sigma_P^2 \) are the variances for security \( i \) and portfolio \( p \), respectively, while \( w_i \) is the proportion of the asset allocated to each security, and \( \rho_{i,j} \) is the correlation of returns between securities \( i \) and \( j \). While MPT is a model that produced innumerous investment successes and nurtured better investing practices, it fails to accurately model risk in the financial markets (Chen (2016)). It had been argued that instead of measuring risk in terms of variance, risk should be measured only based on the probability of investment losses (Keppler (1990); Kim, Kim and Fabozzi (2015)). About 20 years later, Miller et al. developed a different method for risk analysis by introducing the use of coefficient of variation as a *relative measure of risk* (Miller and Karson (1977)). In their method, the coefficient of variation (CV) of one security is compared to the CV of another security using a test statistic to determine if the CV of the two securities differ significantly. The test statistic is complex which may not be accessible by many ordinary investors and are, admittedly, only good when \( n \geq 10 \) and \( \text{CV} \leq 0.67 \) for a one-sided alternative hypothesis, *i.e.*, \( H_0: CV_1 = CV_2 \) versus \( H_a: CV_1 \neq CV_2 \) (Feltz and Miller (1996)), but such a CV is rarely achieved in stocks (see Internet Appendix). This limitation is in addition to the fact that such a test is inaccurate when the data include negative values (Miller and Karson (1977)) which, unfortunately, is common in financial securities’ returns. In fact, Miller *et al.* used historical share prices instead of historical returns perhaps to avoid the inclusion of data with negative values and assumed that the prices under consideration were taken from a normal population (Miller and Karson (1977)). However, such an assumption may be often incorrect as it is well known that share prices have log-normal distribution (Antoniou, Ivanov, Ivanov and Zrelov (2004); Rosenkrantz (2003)).
This manuscript focuses on stock securities and describes an approach that generates stock CVs that are strongly correlated to share price performance. CV can also be used to estimate the probability of the occurrence of negative returns, herein defined as risk, using an equation that is described here for the first time.

II. Deriving risk from the probability density function

The probability density function, $f_X$, is a function that describes a normal distribution and is given by:

$$f_X(x) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad \text{Eq. 3}$$

where $\mu$, $\sigma$, and $\sigma^2$ are the mean, standard deviation, and variance (Naghettini (2017)). In finance, $\mu$ can be the average return of a security, and the distribution of returns has been theoretically and empirically proven to be normal (Fama (1965); Samuelson (2016)). With $\mu$ as the average return, the mean-variance analysis (also known as Modern Portfolio Theory or MPT) then defined $\sigma$ (and $\sigma^2$) as the measure of risk. To illustrate why standard deviation is an inaccurate measure of risk, consider the theoretical normal distribution of returns of portfolios A and B shown in Figure 1. Portfolio A has the larger standard deviation, and therefore should be the riskier portfolio according to MPT. However, its distribution is well within the positive domain, suggesting that this portfolio had not incurred any losses. In contrast, portfolio B has a smaller standard deviation, and this portfolio should have a lower risk according to MPT. However, it is obvious that portfolio B incurred losses and should, therefore, be the riskier portfolio. This example and the similar illustrations previously described (Kim, Kim and Fabozzi (2015)) demonstrate that risk should be defined only as the probability of incurring negative returns. This probability is the area under a normal distribution curve in which returns fall below zero. This area is defined by the probability density function evaluated at $(-\infty, 0]$ shown as follows,

![Figure 1. Theoretical normal distribution of returns of portfolios A and B.](image)
\[
\text{probability of negative returns (risk)} = \int_{-\infty}^{0} \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \, dx \quad \text{Eq. 4}
\]

Equation 4 transforms into an error function (Burkardt (2014); Marsaglia (2004); Weisstein (2002)) shown as follows:

\[
\text{probability of negative returns (risk)} = \frac{1}{2} \left[ 1 + \text{erf} \left( \frac{-\mu}{\sigma \sqrt{2}} \right) \right] \quad \text{Eq. 5}
\]

which can be rewritten as:

\[
\Phi_R = \frac{1}{2} \left[ 1 + \text{erf} \left( \frac{-1}{CV \sqrt{2}} \right) \right] \times 100\% \quad \text{Eq. 6}
\]

where \( \Phi_R \) is the \% probability of occurrence of negative returns (risk) and \( CV = \frac{\sigma}{\mu} \). This equation reveals for the first time the direct relationship between the coefficient of variation and risk. In contrast to using \( CV \) as relative risk as espoused by Miller et al., equation 6 is straightforward and the error function (erf) can be easily accessed in most spreadsheets, calculators, and graphing softwares.

**III. \( \Phi_R \) describes practical market phenomena**

Insights from equation 6 can be derived by plotting risk (\( \Phi_R \)) against standard deviation or volatility (\( \sigma \)) for various returns (\( \mu \)) (Figure 2). The plot suggests that as volatility (\( \sigma \)) increases, risk (\( \Phi_R \)) approaches but never crosses 50%. This observation is interesting because it suggests that so long as the average return (\( \mu \)) is positive, the odds of profiting are better than the odds of losing from an investment. Also apparent from the plot is the inverse relationship between risk (\( \Phi_R \)) and return.

![Figure 2. Plot of risk vs standard deviation for select returns.](image-url)
(blue arrow) which suggests that for the same volatility, assets with lower returns are riskier. Furthermore, it is apparent from the plot that for the same risk (red arrow), assets with higher returns tend to be more volatile. Overall, these observations point to the fact that equation 6 has a basis in the reality of the financial market.

Interestingly, there exists a region for each return where nonzero volatility carries zero risk. This region turns out to be within $0 \leq CV \leq 0.25$ regardless of the magnitude of the return (figure 2). The existence of this risk-free region suggests that volatility is not a risk factor when its magnitude is no more than 0.25 of the return, highlighting the argument that volatility and variance cannot be the true measures of risk.

IV. CV derived from monthly annual returns is strongly correlated to stock performance

This section presents for the first time the strong but inverse correlation between CV and stock performance when CV is calculated using annual returns calculated for each month of the period of interest. For lack of a better description, we shall call it as monthly annual return and is simply described as follows:

$$\frac{\text{month's closing price} - \text{closing price of the same month a year ago}}{\text{closing price of the same month a year ago}} \times 100\% \quad \text{Eq. 7}$$

It can be readily shown that if CV calculation only includes annual returns based on, for example, end-of-year closing prices (Figure 3A), price fluctuations from the intervening months are unaccounted for and often lead to a weak correlation between CV and stock performance. However, when CVs are derived from monthly annual returns (Figure 3B), most of the price fluctuations are accounted for and, therefore, should lead to a strong but inverse correlation between CV and stock performance - this manner of CV calculation is akin to integral calculus. To illustrate this idea, CVs

Figure 3. A. End of year annual returns. B. Monthly annual returns.
calculated from end-of-year vs monthly annual returns of ~3000 stock securities (see Internet Appendix) were generated using monthly closing share prices between 2008-2018 obtained from the Center for Research in Security Prices (CRSP), and calculations only include stock securities with complete historical monthly closing prices. Tickers (retrieved for the year 2020) were included which the reader may use for a quick verification using, for example, Yahoo!/Google Finance (see Internet Appendix). For securities with no tickers, PERMNOs were provided which can be used to retrieve historical share prices from CRSP. Indeed, we found that CVs derived from annual returns based only on end-of-the-year closing prices have a weaker correlation with stock performance. For example, WRB stock (Figure 4A) appears to be riskier compared to BMRN stock (Figure 4B) by comparison of the CVs based on end-of-year closing prices. However, it is apparent from the historical share prices of these two stocks that the WRB share price growth was more consistent than that of BMRN. Reconciliation of the seeming disconnect between CV and stock performance appears to be remediated by using monthly annual returns (compare CVs based on annual monthly returns in Figure 4). The reader is invited to verify this claim by comparing CVs and the performance of the stocks listed in the Internet Appendix using Yahoo!/Google Finance as described above.

**V. Price of stocks with low CV grows exponentially**

Examination of the relationship between CV (see Internet Appendix) and price growth (via Yahoo!/Google Finance) revealed that the price growth of stocks with low CV is approximately
exponential (at least up to 2018). Then, gradual flattening or appearance of large peaks and valleys occur as CV increases or a decline in price growth as CV becomes negative. This observation suggests that stocks with low CV should outperform stocks with high or negative CV. In fact, by calculating the total return between Dec 2008 – Dec 2018 for each stock found in the Internet Appendix, i.e.,

\[
\text{total return} = \frac{\text{Dec } 2018 \ \text{price} - \text{Dec } 2008 \ \text{price}}{\text{Dec } 2008 \ \text{price}} \times 100\% \quad \text{Eq. 8}
\]

we found that stocks with low CV generally produce high returns, i.e., stocks with a CV of up to 2.0 (30% risk) dominate the number of stocks with a total return greater than 100% (see Internet Appendix and figure 5A). This observation is in line with what has been previously observed by Baker et al. and many others (Baker and Haugen (2012); Haugen and Baker (1991); Haugen and Heins (1975); Jagannathan and Ma (2003)), i.e., low-risk stocks outperform in all markets. Our observation here, like the previous observations, goes against the well-established notion in finance that high-risk stocks (or equities) produce higher returns. Also, we can show that only

![Figure 5. A. Plot of total return vs CV for stocks with CV \( \leq \) 10 (see Internet Appendix). B-D. Theoretical risk-free price growth growths.](image-url)
exponential growth can achieve zero risk. Assuming $price = ce^{a+bt}$, where $a, b, c$ are positive constants and $t$ is the number of invested years,

$$risk-free\,\,return\,\,per\,\,year = \frac{ce^{a+2b} - ce^{a+b}}{ce^{a+b}} \times 100\% = \frac{ce^{a+3b} - ce^{a+2b}}{ce^{a+2b}} \times 100$$

$$= \frac{ce^{a+b(t+1)} - ce^{a+bt}}{ce^{a+bt}} \times 100 \quad Eq.\,9$$

which can be simplified to

$$risk-free\,\,return\,\,per\,\,year = (e^b - 1) \times 100\% \quad Eq.\,10$$

and with plots of selected risk-free price growth presented in figure 5B-D. Theoretically, the risk-free return has no limit, but the question is: what distinguishes a high yield risk-free stock from a
stock in a bubble? In theory, the return of a risk-free stock is constant with respect to time. In practice, the return randomly fluctuates around a mean value (figure 6 A-B). For a stock in a bubble, however, the return is either trending up during bubble formation or trending down during bubble rupture (figure 6 C-D).

VI. CV allows calculation of risk along the efficient frontier

A low CV does not always guarantee positive future returns for stock. To mitigate such risk, it has been a practice to build a portfolio, and this idea was mathematically embodied in MPT and gave rise to a very popular investment tool known as the efficient frontier (Fabozzi, Markowitz and Gupta (2008); Markowitz (1952)). MPT suggests that for any group of securities, there exists a set of portfolios offering the highest expected return for any given risk (defined in MPT as $\sigma$). These portfolios lie along the upper half of a curve (see sample curves in Figure 7) that is said to be the efficient frontier (Fabozzi, Markowitz and Gupta (2008); Markowitz (1952)). Portfolios that lie to the left of the efficient frontier are considered to have lower risks but also offer lower returns, whereas portfolios that lie to the right of the efficient frontier are considered to have higher risks but also deliver higher returns. Portfolios that lie below the curve are said to be suboptimal (Fabozzi, Markowitz and Gupta (2008); Markowitz (1952)).

We examined $\Phi_R$ along the efficient curve of a two-security portfolio (Table 1) previously described (Templeton (2013)). The relationship of portfolio expected return ($\mu_p$), standard deviation ($\sigma_p$), and coefficient of variation ($CV_p$) is described as follows:

$$CV_p = \frac{\sigma_p}{\mu_p} = \frac{\sqrt{\left(\sum_{i=1}^n w_i^2 \sigma_i^2 + \sum_{i=1}^n \sum_{j=1}^n 2w_i w_j \rho_{i,j} \sigma_i \sigma_j \quad j \neq i \right)}}{\sum_{i=1}^n w_i \mu_i} \quad Eq. 11$$

For a two-security portfolio, equation 7 is reduced to

$$CV_p = \frac{\sigma_p}{\mu_p} = \frac{\sqrt{[w_1^2 \sigma_1^2 + (1-w_1)^2 \sigma_2^2 + 2w_1 (1-w_1) \rho \sigma_1 \sigma_2]}}{w_1 \mu_1 + (1-w_1) \mu_2} \quad Eq. 12$$

where $w_1$ and $(1-w_1)$ are the proportions of the asset allocated to securities 1 and 2, respectively. The frontiers with correlation $\rho = -1, 0, and 1$ were constructed and described in Figure 6.
Indeed, we observe from the frontier with $\rho = -1$ (Figure 7) that lower $\sigma_p$ is associated with lower $\Phi_R$ and vice versa, and this relationship is maintained even at $\rho = 0$. However, at $\rho = 0$, a comparison of $\mu_p$ and risk (CV or $\Phi_R$) among the portfolios becomes an important consideration. For example, the portfolio that has an expected return $\mu_p = 6.4$ has $\Phi_R \sim 23\%$, while the portfolio with an expected return $\mu_p = 12$ has $\Phi_R \sim 27\%$. The expected return almost doubled but there is

Figure 7. Calculation of CV and $\Phi_R$ along the efficient frontier. Encircled points in each figure correspond to the data of the same highlight color found in each table.

Indeed, we observe from the frontier with $\rho = -1$ (Figure 7) that lower $\sigma_p$ is associated with lower $\Phi_R$ and vice versa, and this relationship is maintained even at $\rho = 0$. However, at $\rho = 0$, a comparison of $\mu_p$ and risk (CV or $\Phi_R$) among the portfolios becomes an important consideration. For example, the portfolio that has an expected return $\mu_p = 6.4$ has $\Phi_R \sim 23\%$, while the portfolio with an expected return $\mu_p = 12$ has $\Phi_R \sim 27\%$. The expected return almost doubled but there is
only a slight increase in $\Phi_R$, suggesting that the portfolio with $\mu_p = 12$ may be the more efficient of the two portfolios. Even more surprising is the fact that the relationship between $\sigma_p$ and $\Phi_R$ is reversed at $\rho = 1$, *i.e.*, lower $\sigma_p$ corresponds to higher $\Phi_R$, and vice versa. These analyses revealed that the direct proportionality between $\sigma_p$ and $\Phi_R$ along the efficient frontier may only hold true for portfolios that have a negative overall correlation. However, the reader is invited to verify that even at a slightly negative correlation (*e.g.*, $\rho = -0.3$), $CV_p$ remains an important consideration. Interestingly, it had been found that inter- and intra-assets are likely to be positively correlated even for assets from a diversified international origin (Chernih, Vanduffel and Henrard (2006); Hunter and Coggin (1990); Newell and Peng (2008); Van Landschoot (2007 )), indicating that $CV_p$ calculation would be the more superior tool than MPT. Judging from the observations from this and the previous section, we can posit that to maximize portfolio returns, one only needs to minimize portfolio CV (minimize risk), but with the caveat that the stocks’ price growths are supported by healthy valuations.

**VII. Summary and Conclusion**

In addition to presenting a method for generating a CV that strongly correlates with stock performance, we also presented here for the first time a mathematical equation that allows us to calculate risk from a CV. This equation perfectly describes known market phenomena and provides confidence for its practical application in risk analysis. The equation also suggests that stocks with high returns are not necessarily risky. In fact, any stock with high returns can be a risk-free investment if its volatility is no more than 25% of its return. This observation appears to contradict the notion that volatility is a measure of risk as proposed by the mean-variance analysis. Finally, we found that stocks with low CV (up to $\sim 2.00$) have approximately exponential price growths and that these stocks appear to be outperforming stocks with high CV (high risk). Recent empirical data by Baker and others suggest that the low risk/high return may indeed be the true risk and return correlation. These observations appear to contradict the notion of high risk/high return as espoused in modern finance. Consequently, it appears that in building a portfolio, one must minimize CV (minimize risk) to maximize returns. It needs to bear in mind though that CV comparison must be done only within an asset class as previously illustrated (Baker and Haugen (2012); Haugen and Heins (1975)) .
VIII. Methodology

The historical monthly raw share prices between December 2018 to December 2019 were downloaded from the Center for Research in Security Prices database which is available at Wharton Research Data Services. The prices were adjusted to reflect stock splits, repurchases, etc. by dividing the raw prices with the corresponding cumulative factor (CFACPR) also downloaded from the same database. Only stocks that have the complete historical monthly closing prices within the aforementioned period were included in the calculation. Bitcoin historical monthly closing prices were downloaded from www.investing.com. All plots were generated using OriginPro 2021 (OriginLab®).

**Notes:**
- Y, X, Z, Y2, X2, Z2 represent the coordinates of the data points.
- The data points are organized in columns, with each column representing a different site.
- The values in each cell represent the corresponding coordinates for each site.
