Ischemic stroke · Hemorrhagic stroke · Bypass surgery

Abstract
Moyamoya disease is an uncommon vascular disease, which causes obstruction and stenosis of arteries of the circle of Willis, and preferentially affects children and young adults. This disease is seen across the world, but is more common in East Asia. It may cause hemorrhagic or ischemic stroke, or transient ischemic attack. If symptoms or cerebral blood flow become worse, revascularization surgery is recommended. We present 2 cases of moyamoya disease who underwent bypass surgery. We also discuss the epidemiology, pathology, genomics, and symptomatology as well as diagnosis, and management of moyamoya disease.

Introduction
Moyamoya disease is a rare, progressive vascular disorder in which arteries of the circle of Willis becomes obstructed or stenosed, reducing blood flow to the brain \cite{1-3}. Moyamoya disease is found all over the world, but it is more common in East Asian countries. There are
two peaks of onset in moyamoya disease [2, 4, 5]; one is in childhood and the other is in young adulthood. Moyamoya disease may cause transient ischemic attack (TIA), stroke, aneurysm, or bleeding in the brain [2, 5, 6]. If symptoms become worse or if tests show evidence of low blood flow, revascularization surgery is recommended. We present 2 cases of moyamoya disease; one had ischemic stroke and the other had hemorrhagic stroke, they both underwent bypass surgery.

**Case 1**

A 44-year-old male had repeated attacks of right hemiparesis after hyperventilation and exercise such as swimming since childhood. He visited a pediatric clinic, but no diagnosis was made, and did not have any further attack. Since 1 year ago, he had frequent tingling of the right upper extremity and muscle cramps of the right lower extremity. Thereafter, he had left hemiparesis after drinking alcohol. He visited a clinic, and was found to have bilateral internal carotid artery (ICA) occlusion and a watershed infarction in the right frontal lobe, and thus was diagnosed with moyamoya disease. He was referred to the Department of Neurosurgery of Tokyo Women’s Medical University Hospital for the purpose of surgery. He had no particular medical history, but his daughter had moyamoya disease.

Upon neurological examination on admission, he had left hemiparesis; 2/5 in the upper extremity and 4/5 in the lower extremity on manual muscle testing. Walking was possible with assistance of a cane. His brain MRI showed an infarction in the frontal watershed area (Fig. 1a). On brain MR angiography, the right ICA was poorly visualized, and the left ICA was obstructed, even though it had been previously treated with carotid artery stenting by a neurosurgeon at another hospital (Fig. 1b). The right conventional cerebral angiography showed complete occlusion of the right ICA distal to the bifurcation of the ophthalmic artery, and anastomosis from the ophthalmic artery to the contralateral anterior cerebral artery territory. There was no indirect anastomosis from the external carotid artery, and only flow from the posterior communicating artery to the right side. His single-photon emission computerized tomography (SPECT) showed extreme reduction of blood flow at rest (Fig. 1c) and steal phenomenon (Fig. 1d) in the right cerebral hemisphere.

The right superficial temporal artery (STA)-middle cerebral artery (MCA) double bypass surgery was performed. After the surgery, good patency of double bypass was confirmed (Fig. 1e). There was no recurrence of stroke thereafter. This was a case in whom diagnosis and surgical intervention were delayed despite frequent episodes. After the surgery, his motivation and activity remarkably improved.

**Case 2**

A 34-year-old male was transferred to the Emergency Department of Tokyo Women’s Medical University because of sudden loss of consciousness. His brain CT showed ventricular hemorrhage (Fig. 2a) and acute hydrocephalus. Drainage of his bilateral lateral ventricles was performed. He was diagnosed with moyamoya disease by cerebral angiography after improvement of consciousness. He was planned to be treated with vascular reconstruction procedure after moving to a rehabilitation hospital. He had medical histories of syphilis and gout, but no particular family history. He had no residual neurological deficits.

On cerebral angiography, there was marked dangerous anastomosis via the left anterior choroidal artery and meningeal anastomosis from the left anterior cerebral artery, and no
stenotic lesion of the posterior cerebral artery. His SPECT showed reduced cerebral blood flow (Fig. 2b) and cerebrovascular reactivity (Fig. 2c) in the left cerebral hemisphere.

He underwent the left STA-MCA double bypass surgery (Fig. 2d). Mild hyperperfusion occurred after the surgery but could be controlled with sedation, analgesia, and blood pressure lowering [7, 8]. His cognitive function improved.

This was a typical case of hemorrhagic stroke with dangerous choroidal anastomosis on cerebral angiography [9]. Only direct bypass surgery is proven to be effective in patients with hemorrhagic type of moyamoya disease.

Discussion

Moyamoya disease is a rare, progressive vascular disorder in which arteries of the circle of Willis become obstructed or stenosed, reducing the blood flow to the brain [1, 3]. Tiny blood vessels then develop at the base of the brain in an attempt to supply blood to the brain. The word “moyamoya” means “puff of smoke” in Japanese, a term describing the appearance of net-like tiny blood vessels.

Moyamoya disease is found all over the world, but it is more common in East Asian countries, especially Japan, Korea, and China, and in people of East Asian descent [4]. Female gender is more prevalent in Japanese and Korean patients [4, 5]. There are two peaks of onset in moyamoya disease [2, 4, 5]; one is in childhood, and the other is in young adults. Ischemic stroke is dominant in children and hemorrhagic stroke is dominant in adults [2, 5, 6].

In autopsy, intimal hyperplasia, atrophic media, and widening of the internal elastic lamina can be seen in affected arteries [2, 5]. In 2011, A genome-wide association study identified RNF213 as the first moyamoya disease gene in Japanese patients with familiar moyamoya disease [10]. In the same year, RNF213 was also identified as a susceptibility gene for not only Japanese but also Korean and Chinese populations [11].

Moyamoya disease may cause TIA, stroke, aneurysm, or bleeding in the brain [2, 5, 6]. It can also cause cognitive and developmental delays or disability. Cerebral angiography of moyamoya disease shows stenosis and occlusion of arteries of the circle of Willis with moyamoya vasculature as developed collateral circulation [2, 3, 12]. Flow void sign suggests moyamoya vasculature on MRI in bilateral basal ganglia [13, 14]. Electroencephalography shows rebuild up of delta waves once hyperventilation is stopped, which is a typical finding in moyamoya disease [2, 11, 15].

Medications are prescribed to reduce the risk of stroke or to control seizure [2]. Aspirin or other antiplatelet drugs are recommended to prevent strokes. Calcium channel blockers may relieve headaches. Anti-seizure medications should be prescribed if the patient has seizure disorder.

If symptoms become worse or if tests show evidence of low blood flow, revascularization surgery is recommended. Direct or indirect revascularization procedures, or a combination of both may be used. Indirect procedures include encephaloduroarteriosynangiosis or encephalomyosynangiosis [2, 12, 16]. In direct revascularization surgery, the scalp artery is sutured directly to a brain artery to immediately increase blood flow to the brain [2, 12, 16]. The Japan Adult Moyamoya (JAM) trial compared bilateral extracranial-intracranial direct bypass and conservative care in 80 patients with moyamoya disease with an age range of 18–65 years. Patients in the bypass surgery group at the primary endpoint experienced significantly less recurrent intracranial hemorrhage, completed stroke, or crescendo TIA, and also experienced
less recurrent bleeding related to death or severe disability at the secondary endpoint compared to the conservative care group [17].

**Statement of Ethics**

The 2 patients presented signed written informed consent forms.

**Conflict of Interest Statement**

The authors have no conflicts of interest to disclose for this report.

**Funding Sources**

The authors did not receive any funding to support this report.
