Prematurity, a significant predictor for worse outcome in viral bronchiolitis: a comparative study in infancy

Noussa R. El Basha 1*, Huda Marzouk 1, May M. Sherif 2 and Amani A. El Kholy 2

Abstract

Background: The rate of admissions to hospital with bronchiolitis has increased over the past years. The reasons for this are likely to be multifactorial including improved survival of preterm infants.

Aim: To assess the severity of viral bronchiolitis in preterm compared to term infants admitted at a tertiary hospital in Cairo, Egypt, based on the outcome.

Patients and methods: This prospective study was conducted throughout a 3-year period from September 2011 to October 2014. It included 153 infants, 74 healthy preterm, and 79 healthy term infants admitted with clinical diagnosis of bronchiolitis at a tertiary hospital in Cairo, Egypt. Bronchiolitis severity score (BSS) was recorded, and nasopharyngeal swabs were obtained from each patient at the time of presentation. Viruses were identified using reverse transcription polymerase chain reaction (RT-PCR). The clinical course and patient’s outcome were recorded.

Results: This study recorded a significantly more severe BSS for preterm compared to term infants. The preterm group had an increased mean length of hospital stay and oxygen therapy and was more likely to need intensive care unit admission and mechanical ventilation (MV) compared to the term group. The mean (± SD) BSS for infections with h-MPV, RSV, and para-influenza 3 was more significantly severe in preterm compared to term infants. Bacterial co-infection was significantly correlated with severity scoring in both groups.

Conclusion: Prematurity significantly affects the severity of bronchiolitis, and this underscores the importance of early categorization as a high-risk group on their first visit. The physician should be aware that their illness runs a more severe course, even if they have no underlying disorders.

Keywords: Bronchiolitis, Viruses, Preterm, Severity

1 Introduction

Bronchiolitis is the most common lower respiratory tract infection in children less than 1 year of age and is usually of viral etiology [1]. Human respiratory syncytial virus (RSV) is the most commonly causing virus and identified in 60–70% of hospitalized infant with bronchiolitis [2]. Bronchiolitis by itself accounts for the greatest number of hospitalization in infancy during the fall and winter season [3].

Bronchiolitis is a self-limiting condition but may be life threatening causing significant severe illness [4–6], and it is the most common cause of hospital admission for infant beyond the neonatal period with rate varying between 1 and 3%. Furthermore, approximately 10% of hospitalized infants will need intensive care admission [7–10].

The rate of admissions to hospital with bronchiolitis has increased over the past 10 years. The reasons for this are not fully understood and are likely to be multifactorial and include improved survival of preterm infants [11].

Epidemiological evidence revealed that young age (less than 6–12 weeks) and premature birth (less than 37 weeks) are associated with high risk of severe bronchiolitis [7, 12, 13].
The aim of the present study was to assess the severity of viral bronchiolitis in healthy preterm compared to healthy term infants in terms of the duration of hospital stay, oxygen saturation and duration of oxygen requirement, and ICU and/or MV requirement.

2 Materials and methods

2.1 Study design and subjects

This prospective study was conducted throughout a 3-year period from September 2011 to October 2014. It included 153 infants in the first year of life with clinical diagnosis of bronchiolitis, according to American Academy of Pediatrics [14], and all were admitted to inpatient departments at the Cairo University Specialized Pediatric Hospital. Seventy-four of those infants were healthy preterm (less than 37 weeks) and 79 infants were healthy term. The following specific groups were excluded: neonates, recurrent wheeze, and association of underlying chronic diseases.

2.2 Ethical considerations

This study was approved by the Cairo University Clinical Research Ethics Committee, and informed verbal consents were obtained from parents of the included children. The study design conformed to the Revised Helsinki Declaration of Bioethics.

3 Methods

All patients were subjected to thorough history taking, including demographic data, and also, full physical examination was performed with emphasis on signs of respiratory tract infection. The respiratory severity score that has been used in this study is the modified Tal score. This score ranges from 0 to 12, with a higher score indicating more severe disease. Each score is an aggregate of assigned values ranging from 0 to 3 in categories of respiratory rate, retractions, wheezing, and oxygen saturation in room air [15]. Bronchiolitis severity score (BSS) was recorded for each patient at the time of presentation. Subsequently, during inpatient management, the following data were recorded: the clinical course was observed during the hospital stay including the need for intensive care unit (ICU) admission, need for mechanical ventilation (MV), duration of oxygen therapy, and duration of hospital stay.

3.1 Clinical specimens

Complete blood count (CBC) and C-reactive protein (CRP) were determined at the time of study enrollment for each patient. Oropharyngeal (OP) and nasopharyngeal (NP) swabs were obtained for PCR at the time of presentation and put in viral transport media (VTM).

3.2 Molecular identification of respiratory viruses

Total nucleic acid (TNA) was extracted from the NP/OP swabs by the automated KingFisher Flex Magnetic Particle Processor (Thermo Scientific, Waltham, USA) using MagMAX Total Nucleic Acid Isolation Kit (Cat No. AM 1840, Applied Biosystems, Foster City, USA) according to the manufacturer's instructions. All the viral targets were amplified using specific primers and probes produced by the Center of Disease Control and Prevention (CDC), Atlanta, USA, and following standard protocol for quantitative reverse transcription PCR detection.

Detection of influenza viruses was conducted in the Cairo University Hospital laboratory and confirmed by the Naval Medical Research Unit No.3 (NAMRU-3) laboratory. The samples were screened for the presence of influenza A and B using the CDC kit for influenza following CDC protocol [16]. Samples positive for influenza A were further subtype according to the CDC protocol to the following types: pandemic influenza 2009 A(H1N1) and seasonal H1 and H3.

Testing for adenovirus; human parainfluenza viruses 1, 2, and 3 (hPIV); respiratory syncytial virus (RSV); and human metapneumovirus (hMPV) was done at NAMRU-3 laboratory by RT-qPCR using CDC specific primers and probes and following a CDC protocol for the detection of non-influenza viruses. Samples were considered positive to the viral target if the amplification curve crossed the threshold line before cycle 40. All clinical samples had to be positive for the human RNAse P gene (RP), with a Ct value ≤ 37, for validation. A positive control for each virus was added to each run to ensure adequate amplification of the target genes.

3.3 Statistical analysis

Precoded data was entered on the Statistical Package of Social Science Software program, version 23 (IBM SPSS Statistics for Windows, Version 23.0. Armonk, NY, IBM Corp.) to be statistically analyzed. Data was presented using mean and standard deviation for quantitative variables and frequency and percentage for qualitative ones. Comparison between groups was performed using independent sample \( t \) test or Mann-Whitney for quantitative variables and chi-square and Fisher’s exact test for qualitative ones. Spearman correlation coefficient was used to estimate the association between different quantitative variables. \( P \) values less than 0.05 were considered statistically significant.

4 Results

The study included 153 infants with a clinical diagnosis of acute bronchiolitis in otherwise healthy infants. Seventy-nine of them were term and 74 were preterm infants. The detailed demographic characteristics including risk factors for bronchiolitis of both preterm
and term infants are summarized in Table 1. Preterm infants were significantly younger than term infants (P value 0.001).

Clinical findings at the time of presentation, BSS, and outcomes of both groups are shown in Table 2. BSS (Mean ± SD) was significantly more severe for preterm compared to term infants at time of presentation (P value 0.045). Also, preterm group had an increased mean length of hospital stay, and mean duration of oxygen therapy compared to term group (P value 0.002 and 0.001, respectively). Preterm infants were significantly more likely to need ICU admission (P value 0.007) and MV (P value 0.033) than term infants.

Viral screening results are summarized in Table 3. Respiratory viruses were detected in 36 (48.6%) preterm patients and in 53 (67%) term patients with acute bronchiolitis. RSV was the most commonly detected virus in both groups, although, more significantly frequent in term infants (57%) than preterm infants (32.4%) (P value 0.003). On the other hand, adenovirus was more significantly frequent in preterm than term infants (16.2% and 5.1%, respectively, P value 0.033). Concomitantly with the viral respiratory infection, preterm patients had more frequent concomitant bacterial infections than term despite non-significance (P value 0.221).

On comparing BSS of different viral agents in preterm and term infants, the mean (± SD) score for h-MPV, RSV, and para-influenza 3 was more significantly severe in preterm compared to term infants (P value 0.003, 0.009, and 0.013, respectively), as shown in Table 4.

On correlating bronchiolitis severity score to screened viruses and outcome in both groups mixed viral infection did not correlate with severity scoring of bronchiolitis in preterm and term groups (P value 0.723, 0.537, respectively). However, bacterial co-infection was significantly more likely to occur in preterm than term infants (P value 0.045).

### Table 1
Demographic characteristics of preterm and term infants with bronchiolitis, Cairo University Specialized Pediatric Hospital

| Variables                        | Preterm infants (n = 74) | Term infants (n = 79) | *P value |
|----------------------------------|--------------------------|-----------------------|----------|
| Age in months (mean ± SD)        | 5.2 ± 4.1                | 7 ± 4.2               | 0.001    |
| Sex                              |                          |                       |          |
| Male                             | 36 (48.6%)               | 41 (51.9%)            | 0.747    |
| Female                           | 38 (51.4%)               | 38 (48.1%)            |          |
| History of passive smoking       | 46 (62.2%)               | 41 (51.9%)            | 0.253    |

| Lethargy                         | 28 (37.8)              | 9 (11.4)           | < 0.001  |
| No drink                         | 34 (45.9)              | 46 (58.2)          | 0.147    |
| Seizures                         | 4 (5.4)                | 2 (2.5)            | 0.431    |
| Vomiting                         | 16 (21.6)              | 36 (45.6)          | 0.002    |
| Oxygen saturation (mean ± SD)    | 85.4 ± 13.1            | 90.6 ± 9.7         | 0.016    |
| Duration of oxygen therapy (mean ± SD) | 4.4 ± 1.7     | 2.9 ± 1.4         | 0.001    |
| PICU admission                   | 18 (24.3)              | 6 (7.6)            | 0.007    |
| Duration of PICU admission (mean ± SD) | 3.8 ± 1.3       | 3.2 ± 0.4         | 0.186    |
| Mechanical ventilation (MV)      | 12 (16.2)              | 4 (5.1)            | 0.003    |
| Duration of MV (mean ± SD)       | 3.3 ± 1.0              | 2.5 ± 1.0          | 0.128    |
| Duration of hospital stay (mean ± SD) | 5.4 ± 1.6        | 4.0 ± 1.6         | 0.002    |
| Bronchiolitis severity score (BSS) |                        |                    |          |
| Mean ± SD                        | 9.6 ± 3.8              | 8.3 ± 3.3          | 0.045    |
| Severe bronchiolitis             | 36 (48.6%)             | 26 (32.9%)         | 0.051    |

*P values < 0.05 is statistically significant
correlated with severity scoring in both groups ($P$ value < 0.001). Also, we found significant correlation between BSS and need for admission. Also, there was significant correlation between severity and duration of hospital stay and oxygen therapy as shown in Table 5.

### 5 Discussion

We identified a viral etiology in 48.6% of preterm infants and in 67% of term infants hospitalized with acute bronchiolitis; one or more viral pathogens were detected. RSV was the most frequently isolated respiratory virus in both preterm and term infants with bronchiolitis, and adenovirus was the second most frequently detected virus in the current study. The predominance of RSV is in concordance with the assertion that this virus is the single most frequently identified lower respiratory tract pathogen in hospitalized infants worldwide [17–20]. Although, RSV significantly affects more term infant in this study, yet it is likely to be associated with more severe disease in preterm infants, this observation is important in planning protocols for bronchiolitis prophylaxis and management in such high-risk preterm infants. Similarly, h-MPV and para-influenza 3 infections were more severe in preterm than term infants. So, physicians treating preterm infants with RSV, h-MPV, and para-influenza 3 bronchiolitis should be aware that their illness is more protracted and runs a more severe course than term infants, even if otherwise healthy.

The low prevalence of virus detection among preterm compared to term infants with acute bronchiolitis in this study could be attributed to other respiratory viruses which were not included in this study such as coronavirus, bocavirus, and rhinoviruses, and may be also explained by the fact that only patients admitted with severe infections were included in our study.

Although there were no significant differences in the length of stay in PICU and the duration of MV among preterm and term, these preterm patients had more frequent need to be managed in PICU, more frequent need for MV, and more prolonged oxygen therapy and hospital stay than term ones. These findings were in consistence with the study by Howidi et al. [21]. These differences may be explained by smaller airway and/or suboptimal immune response in preterm infants. In addition, the significant difference in age between the two groups could partly explain the higher severity among preterm group.

We found also significant correlation between bronchiolitis severity scoring and need of hospital admission, the same as for the duration of hospital stay and duration of oxygen therapy. This was similar to results reported by Ricart et al. [22] who found that severe bronchiolitis had more mean of hospital stay compared to non-severe and more prolonged duration of oxygen and MV. We documented that preterm infants have a more severe form of illness than term infants where we found that prematurity significantly affects the severity score of bronchiolitis. Increased illness severity in infants who had bronchiolitis was discussed in several researches [1, 23]. In this study, we found that preterm infants were significantly younger than those born term, similar to that reported by Fleming et al. [1].

### Table 3 Viral PCR results among preterm and term infants with bronchiolitis

| Viruses      | Viral positive in preterm infants | Viral positive in term infants | *P* value |
|--------------|----------------------------------|--------------------------------|-----------|
| RSV          | 24 (32.4)                        | 45 (57)                        | 0.003     |
| Adenovirus   | 12 (16.2)                        | 4 (5.1)                        | 0.033     |
| h-MPV        | 4 (5.4)                          | 1 (1.3)                        | 0.198     |
| Influenza A  | 8 (10.8)                         | 2 (2.5)                        | 0.051     |
| Influenza B  | 0 (0.0)                          | 0 (0.0)                        | –         |
| Para-influenza 1 | 0 (0.0)                  | 0 (0.0)                        | –         |
| Para-influenza 3 | 2 (2.7)                        | 6 (7.6)                        | 0.278     |
| Mixed viral infection | 12 (16.2)               | 5 (6.3)                        | 0.071     |
| Co-infection with bacterial | 12 (16.2)               | 7 (8.9)                        | 0.221     |

*P* values < 0.05 is statistically significant

### Table 4 Correlation between screened viruses and bronchiolitis severity score (BSS) in preterm and term infants

| Outcome          | Bronchiolitis severity score (mean ± SD) | *P* value |
|------------------|------------------------------------------|-----------|
| Virus            | Preterm                                  | Term      |          |
| RSV              | 9.7 ± 3.9                                 | 7.4 ± 3.1 | 0.009    |
| Adenovirus       | 9.5 ± 4.0                                 | 10.3 ± 2.6| 0.717    |
| h-MPV            | 11.0 ± 1.2                                | 5 ± 0.0   | 0.003    |
| Influenza A      | 10.0 ± 3.4                                | 13.5 ± 2.1| 0.212    |
| Para-influenza 3 | 13.0 ± 0.0                                | 6.7 ± 2.4 | 0.013    |

*P* values < 0.05 is statistically significant
Mixed viral infection and bacterial co-infection in the present study were more frequently observed in preterm compared to term infants with acute bronchiolitis. However, bacterial co-infection was significantly correlated with severity scoring, while mixed viral infection did not correlate with severity scoring of bronchiolitis, and this was in consistence with what was reported by others [22, 24, 25]. This indicates that infection with multiple viruses in infants is a common situation that does not change the clinical course of bronchiolitis. However, some studies have reported an increased risk for severe bronchiolitis in dual viral infection [26–28] or even in some specific viral infections such as RSV and h-MPV co-infection [29–31].

Although respiratory viruses seem to be related to increased risk of severe disease, our data suggest that prematurity have more specific weight in predicting bronchiolitis outcome. So, understanding host susceptibility and immune response of preterm infants to these viruses, as well as targeting the prevention of infection with these viruses in preterm infant, may have even broader implications than only focusing on their role in disease morbidity.

5.1 Limitations of the study
Limiting this study is a possible underestimation of viral etiologies of acute bronchiolitis because testing for rhinoviruses, coronaviruses, and other viruses was not done, and these viruses were previously detected in such patients [32–35]. Also, the enrolled patients were from a single tertiary institution which is a referral center for many local hospitals, so enrolled patients may be more ill than those at other hospitals. The enrolled patients were inpatients only, while patients with mild respiratory symptoms did not undergo diagnostic testing for viral infections; they were treated in outpatient clinics and this could further direct results towards a more severe population and could influence the scores.

### Table 5: Correlating bronchiolitis severity score to screened viruses and outcome in preterm and term infants

| Variable                          | BSS in preterm | P value | BSS in term | P value |
|-----------------------------------|----------------|---------|-------------|---------|
| Screened virus (mean ± SD)        |                |         |             |         |
| h-MPV                             | 11 ± 1.2       | 0.721   | 5 ± 3.3     | 0.329   |
| RSV                               | 9.7 ± 3.9      | 0.676   | 7.4 ± 3.1   | 0.015   |
| Adenovirus                        | 9.5 ± 4        | 0.953   | 10.3 ± 2.6  | 0.233   |
| Para-influenza 3                  | 13 ± 0.0       | 0.214   | 6.7 ± 2.4   | 0.189   |
| Influenza A                       | 10 ± 3.4       | 0.7     | 13.5 ± 2.1  | 0.042   |
| Mixed viral infection             | 9.8 ± 3.6      | 0.723   | 9.2 ± 3.8   | 0.537   |
| Co-infection with bacterial       | 13.7 ± 1.0     | < 0.001 | 13.7 ± 2.0  | < 0.001 |

Outcome (r)\(^a\)

| Outcome                          | BSS in preterm | P value | BSS in term | P value |
|----------------------------------|----------------|---------|-------------|---------|
| Duration of oxygen therapy       | 0.653          | < 0.001 | 0.721       | < 0.001 |
| Duration of hospital stay        | 0.644          | < 0.001 | 0.803       | < 0.001 |
| Duration of PICU admission       | 0.304          | 0.220   | 0.310       | 0.550   |

\(^a\) (r) is coefficient correlation

Mixed viral infection and bacterial co-infection in the present study were more frequently observed in preterm compared to term infants with acute bronchiolitis. However, bacterial co-infection was significantly correlated with severity scoring, while mixed viral infection did not correlate with severity scoring of bronchiolitis, and this was in consistence with what was reported by others [22, 24, 25]. This indicates that infection with multiple viruses in infants is a common situation that does not change the clinical course of bronchiolitis. However, some studies have reported an increased risk for severe bronchiolitis in dual viral infection [26–28] or even in some specific viral infections such as RSV and h-MPV co-infection [29–31].

### 6 Conclusion and recommendations
Prematurity is one of the risk factors that significantly affect the bronchiolitis severity, and this underscores the importance of early categorization of these infants as a high-risk group on their first visit. Physicians treating preterm infants with bronchiolitis should be aware that their illness runs a more severe course than term infant, even if they have no underlying disorders.

### Authors’ contributions
NREB and HM have conducted, analyzed, and drafted the manuscript of this study. MMS and AAEK have performed the laboratory workup. All authors read and approved the final manuscript.

### Ethics approval and consent to participate
This study was approved by Cairo University Clinical Research Ethics Committee, and informed verbal consents were obtained from parents of the included children. Informed verbal consent has been obtained because most of our patient guardian’s are uncomfortable with reading and writing and may be too embarrassed by the written consent process to participate in a research. This informed verbal consent has been approved by Cairo University Clinical Research Ethics Committee as it covers the basic elements of the consent process that include full disclosure of the nature of the research, adequate comprehension on the part of the potential participant, and the participant’s voluntary consent.

### Table 5: Correlating bronchiolitis severity score to screened viruses and outcome in preterm and term infants

| Variable                          | BSS in preterm | P value | BSS in term | P value |
|-----------------------------------|----------------|---------|-------------|---------|
| Screened virus (mean ± SD)        |                |         |             |         |
| h-MPV                             | 11 ± 1.2       | 0.721   | 5 ± 3.3     | 0.329   |
| RSV                               | 9.7 ± 3.9      | 0.676   | 7.4 ± 3.1   | 0.015   |
| Adenovirus                        | 9.5 ± 4        | 0.953   | 10.3 ± 2.6  | 0.233   |
| Para-influenza 3                  | 13 ± 0.0       | 0.214   | 6.7 ± 2.4   | 0.189   |
| Influenza A                       | 10 ± 3.4       | 0.7     | 13.5 ± 2.1  | 0.042   |
| Mixed viral infection             | 9.8 ± 3.6      | 0.723   | 9.2 ± 3.8   | 0.537   |
| Co-infection with bacterial       | 13.7 ± 1.0     | < 0.001 | 13.7 ± 2.0  | < 0.001 |

Outcome (r)\(^a\)

| Outcome                          | BSS in preterm | P value | BSS in term | P value |
|----------------------------------|----------------|---------|-------------|---------|
| Duration of oxygen therapy       | 0.653          | < 0.001 | 0.721       | < 0.001 |
| Duration of hospital stay        | 0.644          | < 0.001 | 0.803       | < 0.001 |
| Duration of PICU admission       | 0.304          | 0.220   | 0.310       | 0.550   |

\(^a\) (r) is coefficient correlation
choice to participate. The study design conformed to the Revised Helsinki Declaration of Bioethics.
