Comparison of EPS Extraction Efficiencies from *Cladophora Glomerata* by Two Chemical Extraction Methods

Hwey-Lin Sheu, Shui-Ping Chang, and Yi-Chao Lee

**Abstract**—For a macroalga *Cladophora glomerata*, the extracellular matrix on the surface of algae cell, extracellular polymeric substances (EPS) has a gel-like structure that could fractioned into loosely bound EPS (LB-EPS) and tightly bound EPS (TB-EPS). The ratio of protein to polysaccharides (P/S) is TB-EPS is higher than LB-EPS. The contents and extraction rate of EPS were compared two chemical extraction methods (formaldehyde-NaOH and NH$_4$OH). The analysis demonstrated that more extraction rates of EPS were achieved by the formaldehyde-NaOH method. The protein to polysaccharides ratio (P/S) in EPS is between 0.299 to 0.375 by formaldehyde-NaOH and between 0.232 to 0.374 by NH$_4$OH. The results indicated that the EPS could be efficiently extracted by the formaldehyde-NaOH method, but the influence of P/S ratios were not obvious.

**Index Terms**—*Cladophora glomerata*, algae, extracellular polymeric substances (EPS), protein, polysaccharide

I. INTRODUCTION

EPS are the products of cellular lysis and hydrolysis of macromolecules with a high molecular weight, and they usually produced by microorganisms [1]-[3]. Based on binding force with cell, the EPS are usually divided into loosely bound EPS (LB-EPS) and tightly bound EPS (TB-EPS) [4]-[6].

*Cladophora* is a genus of large filamentous green algae commonly found in a variety of marine and freshwater and provides habitat and food for numerous organisms. It may be the most abundant macroalga in freshwater worldwide [7]. The cell surface of *C. glomerata* can excrete large amounts of EPS and then form a unique mucilage layer. It is a high potential for EPS exploration algae. However, the EPS extraction methods of *C. glomerata* and the features of EPS were not explored.

The application of algae EPS in the industry has been valued. The demands for natural polymers in various industrial applications have increased, and therefore, novel algae have been used to synthesize high-value products [1], [8], [9].

This study compared the EPS extraction yield of the large freshwater algae *C. glomerata* and the levels of its primary major contents of polysaccharides and proteins with two different chemical extraction methods of NH$_4$OH and formaldehyde-NaOH. We expect to establish an EPS extraction and analysis procedures biotechnology from *C. Glomerata*, and explore its potential in industrial development.

II. MATERIALS AND METHODS

A. Algae and Microscopy

In this study, the species *C. glomerata* were collected from the Zengwun River (23°04′N, 120°04′E) in southern Taiwan. The algae with India ink was applied to visualize the EPS structure in mucilage layer of algae [10], [11] using the microscopy. The algae were washed twice with tap water, placed at room temperature for 2 h naturally drain, and then used for EPS extraction.

B. EPS Extraction

Samples were suspended in a 0.05% NaCl solution and centrifuged at 5000 g for 20 min, with the liquid collected for LB-EPS measurement [12], [13]. The remaining algae samples were resuspended with 0.05% NaCl solution for TB-EPS extraction using Formaldehyde-NaOH and NH$_4$OH chemical method.

1. NH$_4$OH: remaining algae+0.05% (w/w) NaCl solution to 100 ml+50 ml 0.1 M NH$_4$OH at 4°C for 1 h.
2. Formaldehyde-NaOH: remaining algae+0.05% (w/w) NaCl solution to 100 ml+50 ml 36.5% Formaldehyde-NaOH at 4°C for 1 h.

The treated suspension was centrifuged (15000 g) for 20 min with the suspension being collected (Fig. 1).

C. Analysis Method

All chemicals used in this work were of analytical grade. Polysaccharide content was determined by the phenol-sulfuric acid using glucose as a standard [14]. Protein content was determined according to Bradford (1976) with bovine serum albumin BSA, Sigma A2153 100mg/ml [15]. The total EPS content was measured as the sum of these two substances.

III. RESULTS AND DISCUSSION

A. Microscopy and Comparison of Polysaccharide with Protein in EPS

Microscopic examination by India ink reverse staining showed appearance of extracellular matrix on the surface of algae cell. The EPS had a gel-like structure that could fractionated into loosely bound EPS (LB-EPS) and tightly bound EPS (TB-EPS) (Fig. 2). Two chemical extraction methods (formaldehyde-NaOH and NH₄OH) were applied to extract the EPS. The EPS and composition resulting are showed in Table I, Fig. 3 (Formaldehyde-NaOH method) and Table I, Fig. 4 (NH₄OH method). The formaldehyde-NaOH method exhibited the higher efficiency, with the polysaccharide and protein contents of 2.3 mg g⁻¹ and 5.5 mg g⁻¹ in the TB-EPS, respectively. Comparing TB-EPS and LB-EPS, the results also show that polysaccharides rather than proteins became the predominant compositions in TB-EPS.

|                  | 1.16 4.06 5.22 0.232 |
|                  | 1.15 3.29 4.44 0.275 |
B. Comparison of Contents and Composition at Different Extraction Method

The results are shown in Table III and Fig. 5. The data reflect the average results from 6 repeated measurements, which showed that the average EPS extraction yield of formaldehyde-NaOH is greater than NH₄OH, and the variation of P/S ratios.

This study further compared the primary contents of EPS with different extraction methods. The results showed that using different extraction methods can lead to different extraction yields of EPS, the ratios of protein to polysaccharide in EPS also significant different [16].

| Table III: Comparison of Contents and Extraction Yields of EPS by Different Extraction Methods |
| --- |
| EPS extractions | Extracted method | Organic matter contents (mg g⁻¹ fresh algae) |
|     | protein | polysaccharide | EPS(protein + polysaccharide) | Protein/polysaccharide |
| LB-EPS | Formaldehyde-NaOH | 2.14 ± 0.23 | 0.66 ± 0.09 | 2.80 ± 0.36 | 3.27 ± 0.22 |
|     | NH₄OH | 2.14 ± 0.28 | 0.66 ± 0.10 | 2.80 ± 0.32 | 3.28 ± 0.28 |
| TB-EPS | Formaldehyde-NaOH | 2.28 ± 0.26 | 5.52 ± 0.63 | 7.80 ± 0.65 | 0.327 ± 0.028 |
|     | NH₄OH | 1.31 ± 0.17 | 3.71 ± 0.33 | 5.02 ± 0.45 | 0.291 ± 0.047 |

IV. SUMMARY

In this study of macroalgae EPS, the extraction and analysis of EPS is a most challenging work. To compare the extration yields of EPS from C. glomerata mucilage layer (LB-EPS and TB-EPS) and the changes in its primary contents of polysaccharides and proteins with two different chemical extraction methods (formaldehyde-NaOH and NH₄OH), the study results show that: (1) EPS (Both contents of polysaccharide and protein) could be efficiently extracted by formaldehyde-NaOH method. (2) The ratios of protein to polysaccharide in LB-EPS are not obvious different. C. glomerata is a widely distributed dominant macro-green algae. In its natural habitat, C. glomerata has great potential in EPS extraction. These preliminary study results help us understand the extraction methods of EPS applicable to large algae, and the influence on its primary contents.
