Abstract. In this paper, we classify the three-dimensional partially hyperbolic diffeomorphisms whose stable, unstable, and central distributions $E^s$, $E^u$, and $E^c$ are smooth, such that $E^s \oplus E^u$ is a contact distribution, and whose non-wandering set equals the whole manifold. We prove that up to a finite quotient or a finite power, they are smoothly conjugated either to a time-map of an algebraic contact-Anosov flow, or to an affine partially hyperbolic automorphism of a nil-Heis(3)-manifold. The rigid geometric structure induced by the invariant distributions plays a fundamental part in the proof.

Key words: partially hyperbolic diffeomorphisms, rigid geometric structures, Lagrangian contact structures, parabolic Cartan geometries

1. Introduction

In many natural situations, a differentiable dynamical system on a smooth manifold preserves a geometric structure on the tangent bundle, defined by invariant distributions. For instance, if it preserves a Borel measure, then Oseledet’s theorem provides an almost-everywhere-defined splitting of the tangent bundle, given by the rates of expansion or contraction of the tangent vectors by the differentials of the dynamics.

Although invariant geometric structures naturally arise, they are in general highly non-regular (Oseledet’s decomposition is, for instance, only measurable), and this lack of regularity allows considerable flexibility of the dynamics: former examples can be deformed in order to produce many new ones. By contrast, the smoothness of the invariant distributions puts a strong restriction on the system, and the known examples with smooth (that is, $C^\infty$) distributions are in general ‘very symmetric’: typically, they arise from compact quotients of Lie groups, with action by affine automorphisms.

It is thus natural to ask to what extent the geometric structure preserved by the dynamics makes the situation rigid, and especially why.
Let us give a paradigmatic example of rigidity with the following result of Étienne Ghys concerning three-dimensional Anosov flows (the statement proved by Ghys in [Ghy87] is more precise than the one given below).

**Theorem 1.1.** [Ghy87] Let \((\phi^t)\) be an Anosov flow of a three-dimensional closed connected manifold. If the stable and unstable distributions of \((\phi^t)\) are smooth, then either:

- \((\phi^t)\) is smoothly conjugated to the suspension flow of a hyperbolic automorphism of the two-torus; or
- \((\phi^t)\) is smoothly orbit equivalent to a finite covering of the geodesic flow of a compact hyperbolic surface.

We recall that a smooth non-singular flow \((\phi^t)\) of a compact manifold \(M\) is Anosov if its differentials preserve two distributions \(E^s\) and \(E^u\), respectively called the stable and unstable distributions of \((\phi^t)\), satisfying \(TM = E^s \oplus \mathbb{R}(d\phi^t/dt) \oplus E^u\), such that \(E^s\) is uniformly contracted by \((\phi^t)\), and \(E^u\) is uniformly expanded by \((\phi^t)\).

Under the smoothness assumption of \(E^s\) and \(E^u\), Ghys notes that the plane distribution \(E^s \oplus E^u\) can only have two extreme geometrical behaviours: either it integrates into a foliation, or it is a contact distribution (that is, it is locally the kernel of a contact one-form). In the first case, former results of Plante and Franks conclude the proof and lead to the suspension examples. The work of Ghys in [Ghy87] is therefore almost entirely devoted to three-dimensional contact-Anosov flows, that is, when \(E^s\) and \(E^u\) are smooth, and \(E^s \oplus E^u\) is contact. Under these geometrical assumptions, the pair \((E^s, E^u)\) is a rigid geometric structure preserved by the Anosov flow, which makes the classification possible and leads to the finite coverings of geodesic flows.

In this paper, we investigate the same type of geometrical rigidity conditions but for the discrete-time analogues of Anosov flows that are the partially hyperbolic diffeomorphisms.

1.1. Principal results. We refer to [CP15] for a very complete introduction to partially hyperbolic diffeomorphisms, for which we use the following definition.

**Definition 1.2.** A smooth diffeomorphism \(f\) of a compact manifold \(M\) is partially hyperbolic if it preserves a splitting \(TM = E^s \oplus E^u \oplus E^c\) of the tangent bundle into three non-zero continuous distributions, such that there exists a Riemannian metric on \(M\) with respect to which the following dynamical conditions hold.

- The stable distribution \(E^s\) is uniformly contracted by \(f\), that is, for any \(x \in M\) and any unit vector \(v^s \in E^s(x)\), \(|\|D_x f(v^s)\|| < 1\).
- The unstable distribution \(E^u\) is uniformly expanded by \(f\), that is, uniformly contracted by \(f^{-1}\).
- The splitting is dominated, that is, for any \(x \in M\) and any unit vectors \(v^s \in E^s(x)\), \(v^c \in E^c(x)\), and \(v^u \in E^u(x)\), \(|\|D_x f(v^s)\|| < \|D_x f(v^c)\| < \|D_x f(v^u)\|\) (\(E^c\) is called the central distribution).

The three invariant distributions of a partially hyperbolic diffeomorphism have in general no reasons to be differentiable, but we study in this paper the particular case
when they are smooth, that is, $C^\infty$, and when $E^s \oplus E^u$ is furthermore a contact distribution.

The (non-zero) time maps of the contact-Anosov flows appearing in Ghys’ Theorem 1.1 give us the first examples satisfying these geometrical conditions. They have the following nice algebraic description (see [Ghy87] for more details). Let us denote by $\tilde{A} = \{a^t\}_{t \in \mathbb{R}}$ the one-parameter subgroup of the universal cover $\tilde{SL}_2(\mathbb{R})$ of $SL_2(\mathbb{R})$ generated by $(1, 0, 0, -1) \in sl_2$. Then, for any cocompact lattice $\Gamma_0$ of $\tilde{SL}_2(\mathbb{R})$, the flow $(R_{a^t})$ of right translations by $\tilde{A}$ on the quotient $\Gamma_0 \backslash \tilde{SL}_2(\mathbb{R})$ is a finite covering of the geodesic flow of a compact hyperbolic surface (up to a constant rescaling of the time by a factor of $1/2$), and is thus Anosov. Moreover, if a morphism $u : \Gamma_0 \to \tilde{A}$ is such that the graph-group $\Gamma = \{(\gamma, u(\gamma)) \mid \gamma \in \Gamma_0\}$ acts freely, properly, and cocompactly on $\tilde{SL}_2(\mathbb{R})$ by the action $(g, a) \cdot x = gx a$, then $(R_{a^t})$ still induces an Anosov flow of the quotient $\Gamma_0 \backslash \tilde{SL}_2(\mathbb{R})$, which is a time-change of the former one (non-trivial if $u \neq \text{id}$). We call these flows the three-dimensional algebraic contact-Anosov flows.

By contrast, the following algebraic examples are time-maps of none Anosov flows. For $(\lambda, \mu) \in \mathbb{R}^+\times\mathbb{R}$, we consider the automorphism

$$\varphi_{\lambda, \mu} : \begin{pmatrix} 1 & x & z \\ 0 & 1 & y \\ 0 & 0 & 1 \end{pmatrix} \in \text{Heis}(3) \mapsto \begin{pmatrix} 1 & \lambda x & \lambda \mu z \\ 0 & 1 & \mu y \\ 0 & 0 & 1 \end{pmatrix} \in \text{Heis}(3)$$

(1.1)

of the Heisenberg group. If $\varphi = \varphi_{\lambda, \mu}$, $g \in \text{Heis}(3)$, $\Gamma$ is a cocompact lattice of $\text{Heis}(3)$, and $g\varphi(\Gamma)g^{-1} = \Gamma$, then $L_g \circ \varphi(\Gamma x) = \Gamma(g\varphi(x))$ is a well-defined diffeomorphism of the nil-$\text{Heis}(3)$-manifold $\Gamma \backslash \text{Heis}(3)$. If we moreover assume that either $|\lambda| < 1$ and $|\mu| > 1$, or the opposite, then $L_g \circ \varphi$ is a partially hyperbolic diffeomorphism, whose invariant distributions are smooth, such that $E^s \oplus E^u$ is contact (see §4.1.2). Concrete examples of cocompact lattices preserved by such automorphisms indeed exist, and we will call $L_g \circ \varphi$ a partially hyperbolic affine automorphism. We emphasize the existence in dimension three of partially hyperbolic automorphisms of nil-manifolds (distinct from tori), by contrast with the uniformly hyperbolic case, that is, the one of Anosov automorphisms of nil-manifolds. In [LW09], the authors prove that an Anosov automorphism of a nil-manifold of dimension less than eight which is not covered by a torus can only occur in dimension six or eight. Examples of such automorphisms in dimension six are given in [Sma67, §1.3], along with several general properties of Anosov automorphisms.

The principal result of this paper is that assuming all points are non-wandering, there are no other examples than the two families we described previously.

**Theorem A.** Let $M$ be a closed, connected and orientable three-dimensional manifold, and let $f$ be a partially hyperbolic diffeomorphism of $M$ such that:

- the stable, unstable, and central distributions $E^s$, $E^u$, and $E^c$ of $f$ are smooth;
- $E^s \oplus E^u$ is a contact distribution; and
- the non-wandering set $NW(f)$ equals $M$.

Then we have the following description.

1. Either some finite power of $f$ is smoothly conjugated to a non-zero time-map of a three-dimensional algebraic contact-Anosov flow; or
f lifts by a covering of order at most four to a partially hyperbolic affine automorphism of a nil-Heis(3)-manifold.

Actually, our geometrical conditions are so rigid that the uniformity of the contraction and the expansion of the diffeomorphism will be obtained as a byproduct.

**Definition 1.3.** We will say that a distribution \( E \) of a compact manifold \( M \) is weakly contracted by a diffeomorphism \( f \) if for some Riemannian metric on \( M \), we have for any \( x \in M \):

\[
\lim_{n \to +\infty} \|D_x f^n|_E\| = 0 \quad \text{or} \quad \lim_{n \to -\infty} \|D_x f^n|_E\| = 0. \tag{1.2}
\]

We emphasize that the ‘direction’ of weak contraction can a priori change from point to point, and that this notion is unchanged when replacing \( f \) by \( f^{-1} \). Definition 1.3 is closely related to the notion of quasi-Anosov diffeomorphism investigated by Mañé in [Mañ77]. (More precisely, to the one of a quasi-Anosov isomorphism of a vector bundle; see [Mañ77, Definition 3], which should be applied here to the quotient bundle \( TM/E^c \).) However, in the absence of uniformity on \( M \) of the limit (1.2), we cannot find any clear implication between Definition 1.3 and the unboundedness appearing with quasi-Anosov diffeomorphisms.

**Theorem B.** Let \( M \) be a closed, connected, and orientable three-dimensional manifold, endowed with a smooth splitting \( TM = E^\alpha \oplus E^\beta \oplus E^c \) such that \( E^\alpha \oplus E^\beta \) is a contact distribution. Let \( f \) be a smooth diffeomorphism of \( M \) that preserves this splitting, such that:

- each of the distributions \( E^\alpha \) and \( E^\beta \) is weakly contracted by \( f \); and
- \( f \) has a dense orbit.

Then the conclusions of Theorem A hold. In particular, \( f \) is a partially hyperbolic diffeomorphism.

Theorem A will directly follow from Theorem B by an argument of Brin, as explained in §8.2 at the end of this paper. We also give in this section a precise statement of Theorem A that does not use any domination hypothesis on \( E^c \) (see Corollary 8.2). The rest of the paper is devoted to the proof of Theorem B.

The classification question for partially hyperbolic diffeomorphisms in dimension three has led to much work in recent years, and significant progress has been made concerning the general case, as can be seen, for instance, in the survey [HP18]. Recently, different additional rigidity conditions have also been studied.

Carrasco, Pujals, and Rodriguez-Hertz obtain in [CPRH21] a classification result under the smoothness assumption of invariant distributions. In contrast to Theorem A, no additional geometrical condition is assumed, but the authors assume that the differential of the partially hyperbolic diffeomorphism is constant when read in the global frame given by three smooth vector fields generating these distributions. The geometric structure \((E^s, E^u, E^c)\) defined by such a partially hyperbolic diffeomorphism is in general not rigid, and their result is obtained through dynamical arguments.
Beside the smoothness assumption on invariant distributions, Bonatti and Zhang obtain in \[\text{BZ20}\] different rigidity results in the continuous category, under specific dynamical assumptions.

1.2. A rigid geometric structure preserved by partially hyperbolic diffeomorphisms. Roughly speaking, a rigid geometric structure is a structure with ‘few automorphisms’. More precisely, it is one of those smooth geometric structures whose Lie algebra of local Killing fields (that is, local vector fields whose flow preserves the structure) is everywhere finite dimensional.

As d’Ambra and Gromov pointed out in \[\text{GD91}\], it is natural to believe that rigid geometric structures preserved by rich dynamical systems have to be particularly peculiar: ‘one does not expect rigid geometry to be accompanied by rich dynamics’ \[\text{GD91}, \S 0.3, \text{p. 21}\]. It seems therefore reasonable to look for classification results in these situations. The general idea is that rich dynamical properties will imply strong restrictions on the rigid geometric structure, inducing in return a rigidity of the dynamical system itself.

Several rigid geometric structures can be preserved by a contact-Anosov flow \((\varphi^t)\). First, \((\varphi^t)\) always preserves a contact one-form \(\alpha\), and the induced volume form \(\alpha \wedge d\alpha\) is thus also preserved, that is, contact-Anosov flows are conservative. For contact-Anosov flows of any odd dimension, \((\varphi^t)\) moreover preserves a natural linear connection on the tangent bundle, initially defined by Kanai in \[\text{Kan88}\]. An invariant connection of this kind allowed, for example, Benoist, Foulon, and Labourie to obtain a classification result for contact-Anosov flows of any odd dimension in \[\text{BFL92}\].

While these invariant rigid geometric structures require the existence of a continuous one-parameter flow, we study in this paper rigid geometric structures preserved by discrete-time dynamics.

The transition from a flow to a diffeomorphism completely changes the situation. From a dynamical point of view, partially hyperbolic diffeomorphisms of ‘contact’ type no longer preserve a contact one-form and are thus (\textit{a priori}) not conservative (which explains the extra hypothesis on non-wandering points). From a geometrical point of view, the difficulties that appear are analogous to the ones of a conformal geometry, in contrast to a metric geometry; for example, the invariant Kanai connection no longer exists. This situation requires one to look for a new rigid geometric structure.

A contact plane distribution is far from being rigid; according to Darboux’s theorem, they are all locally isomorphic. A single smooth one-dimensional distribution in a contact plane distribution is still not sufficient to make it rigid. But if the stable and unstable distributions of the partially hyperbolic diffeomorphism are smooth and of contact sum, then the pair \((E^s, E^u)\) is a rigid geometric structure, called a \textit{Lagrangian contact structure}.

For this structure, the invariant Kanai connection will be replaced by another type of connection called a \textit{Cartan connection}, which defines a \textit{Cartan geometry} (actually, this Cartan geometry partially appears in \[\text{Ghy87}\] but under the disguised form of ‘the geometry of second-order ordinary differential equations’). The strength of Cartan geometries is to link the Lagrangian contact structures with the \textit{homogeneous model space} \(X = \text{PGL}_3(\mathbb{R})/\text{P}_{\text{min}}\) of complete flags of \(\mathbb{R}^3\) (where \(\text{P}_{\text{min}}\) is the subgroup of
upper-triangular matrices). In particular, the flat Lagrangian contact structures, that is, the ones whose curvature identically vanishes, are locally isomorphic to $X$ (see §§2.2.2 and 2.3.2). The geometry of $X$ will thus have a prominent role in this paper.

In [Bar10], Barbot also studied the geometry of $X$ and the dynamics of $\text{PGL}_3(\mathbb{R})$ but with a different approach. His purpose, among others, was to construct Anosov representations in $\text{PGL}_3(\mathbb{R})$ and compact quotients of open subsets of $X$.

1.3. **Organization of the paper.** This paper is organized in the following way. Section 2 introduces several notions and results about three-dimensional Lagrangian contact structures that will be used throughout the whole paper. At the end of the paper in §8.2, we prove Theorem A from Theorem B; the rest of the paper is devoted to the proof of Theorem B. In §3, we begin this proof by showing that the triplet $S = (E^\alpha, E^\beta, E^c)$ is quasi-homogeneous, that is, locally homogeneous in restriction to a dense open subset $\Omega$ of $M$, and that its isotropy on $\Omega$ is non-trivial. This implies that the Lagrangian contact structure $(E^\alpha, E^\beta)$ is flat, that is, that $M$ has a $(\text{PGL}_3(\mathbb{R}), X)$-structure. In §4, we refine this description, proving that $S|_{\Omega}$ is locally isomorphic to one of two possible homogeneous models, $(Y_t, S_t)$ or $(Y_a, S_a)$. This relies on a technical classification of the underlying infinitesimal model, done in §5. A critical step is to show in §6 that the open dense subset $\Omega$ is actually equal to $M$, implying that $M$ has a $(H, Y)$-structure, with two possible models, $(H_t, Y_t)$ and $(H_a, Y_a)$. We prove in §7 that this $(H, Y)$-structure is complete, implying that $(M, S)$ is a compact quotient $\Gamma \backslash Y$ of one of these two models, with $\Gamma$ a discrete subgroup of $H = \text{Aut}(Y)$. This description allows us to conclude the proof of Theorem B in §8.1.

1.4. **Conventions and notation.** From now on, every differential geometric object will be assumed to be smooth (that is, $C^\infty$) if not otherwise specified, and the manifolds will be assumed to be boundaryless.

The flow of a vector field $X$ is denoted by $(\varphi^t_X)$. The Lie algebra of a Lie group $G$ is denoted by $\mathfrak{g}$, and for any $v \in \mathfrak{g}$, we denote by $\tilde{v}$ the left-invariant vector field of $G$ generated by $v$. If $\Theta : G \times M \to M$ is a smooth group action (on the left or the right) of $G$ on a manifold $M$, then the orbital map of the action at $x \in M$ is denoted by $\theta_x = \Theta(\cdot, x)$, and we denote by $L_g = \Theta(g, \cdot)$ the translation by $g \in G$ if the action is on the left (respectively by $R_g$ if the action is on the right). For any $v \in \mathfrak{g}$ we denote by $v^\dagger$ the fundamental vector field of the action generated by $v$, defined for $x \in M$ by $v^\dagger(x) = D_e \theta_x(v)$.

2. **Three-dimensional Lagrangian contact structures**

The following rigid geometric structures will be studied in the rest of this paper.

**Definition 2.1.** A Lagrangian contact structure $\mathcal{L}$ on a three-dimensional manifold $M$ is a pair $\mathcal{L} = (E^\alpha, E^\beta)$ of transverse one-dimensional smooth distributions, such that $E^\alpha \oplus E^\beta$ is a contact distribution. An enhanced Lagrangian contact structure $S$ on $M$ is a triplet $S = (E^\alpha, E^\beta, E^c)$ of one-dimensional smooth distributions such that $TM = E^\alpha \oplus E^\beta \oplus E^c$, and $E^\alpha \oplus E^\beta$ is a contact distribution.
A (local) isomorphism between two Lagrangian contact structures is a (local) diffeomorphism that individually preserves the distributions $\alpha$ and $\beta$, and the (local) isomorphisms of enhanced Lagrangian contact structures preserve in addition the central distribution $E^c$.

We first define what will be for us the most important example of a three-dimensional Lagrangian contact structure.

2.1. Homogeneous model space. We will call a projective line the projection in $\mathbb{R}P^2$ of a plane of $\mathbb{R}^3$, and we denote by $\mathbb{R}P^2_*$ the set of projective lines of $\mathbb{R}P^2$ (called the dual projective plane). For any subset $Q$ of $\mathbb{R}^{n+1}$ we denote by $[Q]$ the projection in $\mathbb{R}P^n$ of the linear subspace of $\mathbb{R}^{n+1}$ generated by $Q$.

A pointed projective line is a pair $(m, D)$ with $D \in \mathbb{R}P^2_*$ and $m \in D$, and we denote by $X=\{(m, D) | D \in \mathbb{R}P^2_*, m \in D\} \subset \mathbb{R}P^2 \times \mathbb{R}P^2_*$ the space of pointed projective lines. In other words, $X$ is the space of complete flags of $\mathbb{R}^3$.

Throughout the paper, we denote by $G=\text{PGL}_3(\mathbb{R})$ the group of projective transformations of $\mathbb{R}P^2$. As the projective action of $G$ on $\mathbb{R}P^2$ and $\mathbb{R}P^2_*$ preserves the incidence relation $m \in D$, it induces a natural diagonal action of $G$ on $X$. The action of $G$ on $X$ is transitive, and the stabilizer in $G$ of the base-point $o = ([e_1], [e_1, e_2])$ of $X$ is the subgroup

$$\text{Stab}_G(o) = \text{P}_{\text{min}} = \left\{ \begin{bmatrix} * & * & * \\ 0 & * & * \\ 0 & 0 & * \end{bmatrix} \right\} \subset G$$

of upper-triangular matrices. From now on, we will identify $X$ and $G/\text{P}_{\text{min}}$ by the orbital map $\bar{\theta}_o: G/\text{P}_{\text{min}} \to X$ at $o$. The homogeneous space $X$ is a $\mathbb{R}P^1$-bundle over $\mathbb{R}P^2$ and $\mathbb{R}P^2_*$ through the coordinate projections

$$\pi_\alpha: (m, D) \in X \mapsto m \in \mathbb{R}P^2 \quad \text{and} \quad \pi_\beta: (m, D) \in X \mapsto D \in \mathbb{R}P^2_*.$$  \hspace{1cm} (2.1)

For $x = (m, D) \in X$, we will denote by $C^\alpha(x) = C^\alpha(m)$ (respectively $C^\beta(x) = C^\beta(D)$) the fibre of $x$ with respect to $\pi_\alpha$ (respectively $\pi_\beta$), and we will call it the $\alpha$-circle (respectively the $\beta$-circle) of $x$. We denote by

$$E^\alpha = \text{Ker}(D\pi_\alpha) \quad \text{and} \quad E^\beta = \text{Ker}(D\pi_\beta)$$

the one-dimensional vertical distributions of these bundles, tangent to the foliations by $\alpha$- and $\beta$-circles, respectively. The sum $E^\alpha \oplus E^\beta$ is contact, and we will call $L_X = (E^\alpha, E^\beta)$ the standard Lagrangian contact structure of $X$.

Lemma 2.2. The group $G$ is the group of automorphisms of the standard Lagrangian contact structure $L_X$. In particular, the structure $(X, L_X)$ is homogeneous.
Proof. First, the action of \( G \) preserves the foliations of \( X \) by \( \alpha \)- and \( \beta \)-circles, that is, it preserves the structure \( \mathcal{L}_X = (\mathcal{E}^\alpha, \mathcal{E}^\beta) \). Conversely, if \( f \) is a diffeomorphism of \( X \) that preserves \( \mathcal{L}_X \), the fact that \( f \) preserves the foliation by \( \alpha \)-circles simply means that it induces a diffeomorphism \( \tilde{f} \) of \( \mathbb{P}^2 \) for which \( f \) is a lift through the projection \( \pi_\alpha \). As \( f \) moreover preserves the foliation by \( \beta \)-circles, \( \tilde{f} \) maps any projective line to a projective line. This implies that \( \tilde{f} \) is a projective transformation according to a classical result of projective geometry (proved, for example, in [Sam89, Theorem 7, p. 32]), that is, \( f \) is induced by the action of an element of \( G \).

2.2. Lagrangian contact structures as Cartan geometries. We now introduce the Cartan geometries modelled on the homogeneous space \( G/P_{\text{min}} \), and make the link with Lagrangian contact structures. This notion will be our principal technical tool to deal with Lagrangian contact structures. We refer the reader to [Sha97, ČS09] for further details about Cartan geometries in a more general context.

2.2.1. Cartan geometries modelled on \( G/P_{\text{min}} \).

Definition 2.3. A Cartan geometry \( C = (\hat{M}, \omega) \) modelled on \( G/P_{\text{min}} \) on a three-dimensional manifold \( M \) consists of the data of a \( P_{\text{min}} \)-principal bundle over \( M \) denoted by \( \pi: \hat{M} \to M \) and called the Cartan bundle, together with a \( \mathfrak{sl}_3 \)-valued one-form \( \omega: T\hat{M} \to \mathfrak{sl}_3 \) on \( \hat{M} \) called the Cartan connection, that satisfies the three following properties:

1. \( \omega \) defines a parallelism of \( \hat{M} \), that is, for any \( \hat{x} \in \hat{M} \), \( \omega_{\hat{x}} \) is a linear isomorphism from \( T_{\hat{x}}\hat{M} \) to \( \mathfrak{sl}_3 \);
2. \( \omega \) reproduces the fundamental vector fields of the right action of \( P_{\text{min}} \), that is, for any \( v \in \mathfrak{p}_{\text{min}} \) and \( \hat{x} \in \hat{M} \) we have \( v^\flat(\hat{x}) = (d/dt)|_{t=0}\hat{x} \cdot e^{tv} = \omega_{\hat{x}}^{-1}(v) \); and
3. \( \omega \) is \( P_{\text{min}} \)-equivariant, that is, for any \( p \in P_{\text{min}} \) and \( \hat{x} \in \hat{M} \) we have \( R_p^*\omega = \text{Ad}(p)^{-1} \circ \omega \) (where \( \text{Ad}(p) \) is the adjoint action of \( p \)).

A (local) automorphism \( f \) of the Cartan geometry \( C \) between two open sets \( U \) and \( V \) of \( M \) is a (local) diffeomorphism from \( U \) to \( V \) that lifts to a \( P_{\text{min}} \)-equivariant (local) diffeomorphism \( \hat{f} \) between \( \pi^{-1}(U) \) and \( \pi^{-1}(V) \), such that \( \hat{f} \) preserves the Cartan connection \( \omega \) (that is, \( \hat{f}^*\omega = \omega \)).

Example 2.4. The homogeneous model space \( X \) is endowed with the Cartan geometry of the model \( C_X = (G, \omega_G) \), given by the canonical \( P_{\text{min}} \)-bundle \( \pi_G: G \to G/P_{\text{min}} = X \) over \( X \), together with the Maurer–Cartan one-form \( \omega_G: TG \to \mathfrak{sl}_3 \) defined by \( \omega_G(\tilde{v}) \equiv v \) on the left-invariant vector fields of \( G \).

We consider for the rest of this subsection a Cartan geometry \( (M, C) = (M, \hat{M}, \omega) \) modelled on \( G/P_{\text{min}} \).

2.2.2. Curvature of a Cartan geometry. The following definition replaces the curvature of a Riemannian metric in the case of Cartan geometries.
Definition 2.5. The curvature form of $\mathcal{C}$ is the $\mathfrak{sl}_3$-valued two-form $\Omega$ of $\hat{M}$ defined by the following relation for two vector fields $X$ and $Y$ on $\hat{M}$:

$$\Omega(X, Y) = d\omega(X, Y) + [\omega(X), \omega(Y)].$$

(2.2)

Thanks to the connection $\omega$, the curvature form $\Omega$ is equivalent to a curvature map $K : \hat{M} \to \text{End}(\Lambda^2 \mathfrak{sl}_3, \mathfrak{sl}_3)$ on $\hat{M}$ (that we will often simply call the curvature of $\mathcal{C}$), having values in the vector space of $\mathfrak{sl}_3$-valued alternated bilinear maps on $\mathfrak{sl}_3$, and defined by the following relation for $\hat{x} \in \hat{M}$ and $v, w \in \mathfrak{sl}_3$:

$$K_{\hat{x}}(v, w) = \Omega(\omega_{\hat{x}}^{-1}(v), \omega_{\hat{x}}^{-1}(w)).$$

(2.3)

We say that the Cartan geometry $\mathcal{C}$ (or the Cartan connection $\omega$) is torsion-free if $K_{\hat{x}}(v, w) \in \mathfrak{p}_{\text{min}}$ for any $\hat{x} \in \hat{M}$ and $v, w \in \mathfrak{sl}_3$.

If $v$ or $w$ is tangent to the fibre of the principal bundle $\hat{M}$, then the curvature form satisfies $\Omega(v, w) = 0$ (this is proved in [Sha97, Ch. 5 Corollary 3.10]). As $\omega$ maps the tangent space of the fibres to $\mathfrak{p}_{\text{min}}$ (because the fundamental vector fields are $\omega$-invariant), this implies that the curvature $K(v, w)$ vanishes whenever $v$ or $w$ is in $\mathfrak{p}_{\text{min}}$. As a consequence, at any point $\hat{x} \in \hat{M}$, $K_{\hat{x}}$ induces a $\mathfrak{sl}_3$-valued alternated bilinear map on $\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}$, and in what follows we will identify $K$ with the induced map

$$K : \hat{M} \to \text{End}(\Lambda^2(\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}), \mathfrak{sl}_3).$$

(2.4)

The adjoint action of $\mathfrak{p}_{\text{min}}$ induces a linear left action on $\text{End}(\Lambda^2(\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}), \mathfrak{sl}_3)$ defined for $p \in \mathfrak{p}_{\text{min}}$ and $K \in \text{End}(\Lambda^2(\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}), \mathfrak{sl}_3)$ by

$$p \cdot K : u \wedge v \mapsto \text{Ad}(p) \cdot (K(\text{Ad}(p)^{-1} \cdot u, \text{Ad}(p)^{-1} \cdot v)).$$

(2.5)

Using the linear right action of $\mathfrak{p}_{\text{min}}$ on $\text{End}(\Lambda^2(\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}), \mathfrak{sl}_3)$ defined by $K \cdot p := p^{-1} \cdot K$, $K$ is $\mathfrak{p}_{\text{min}}$-equivariant (this is proved in [Sha97, Ch. 5 Lemma 3.23]), and $K$ is moreover preserved by any local automorphism $f$ of the Cartan geometry (that is, $K \circ f = K$ for any automorphism).

2.2.3. Lagrangian contact structure induced by a Cartan geometry. At any point $x \in M$ and for any $\hat{x} \in \pi^{-1}(x)$, we denote by $i_{\hat{x}} : T_x M \to \mathfrak{sl}_3/\mathfrak{p}_{\text{min}}$ the unique isomorphism satisfying

$$i_{\hat{x}} \circ D_{\hat{x}}\pi = \bar{\omega}_{\hat{x}},$$

(2.6)

where $\bar{\omega}$ denotes the projection of $\omega$ on $\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}$. As the adjoint action of $\mathfrak{p}_{\text{min}}$ preserves $\mathfrak{p}_{\text{min}}$, it induces a representation $\overline{\text{Ad}} : \mathfrak{p}_{\text{min}} \to \text{GL}(\mathfrak{sl}_3/\mathfrak{p}_{\text{min}})$ on the quotient, and the equivariance of $\omega$ implies the following relation for any $p \in \mathfrak{p}_{\text{min}}$:

$$i_{\hat{x}} \cdot p = \overline{\text{Ad}}(p)^{-1} \circ i_{\hat{x}}.$$

(2.7)

This relation shows that any $\overline{\text{Ad}}(\mathfrak{p}_{\text{min}})$-invariant object on $\mathfrak{sl}_3/\mathfrak{p}_{\text{min}}$ gives rise, through the isomorphisms $i_{\hat{x}}$, to a well-defined object on the tangent bundle of $M$. Let us apply this idea to define a Lagrangian contact structure on $M$ associated with the Cartan geometry $\mathcal{C}$. 

We introduce
\[ e_\alpha = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad e_\beta = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad e_0 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \] (2.8)

defining a basis \((\bar{e}_\alpha, \bar{e}_\beta, \bar{e}_0)\) of sl\(_3/\mathfrak{p}_{\text{min}}\), in which the matrix of the adjoint action of \(\mathfrak{p}_{\text{min}} = \begin{pmatrix} a x z \\ 0 \\ a^{-1} b^{-1} \\ y \\ 0 \end{pmatrix} \in \mathbf{P}_{\text{min}}\) is equal to
\[ \text{Mat}(\bar{e}_\alpha, \bar{e}_\beta, \bar{e}_0)(\text{Ad}(p)) = \begin{pmatrix} a^{-2} b^{-1} & 0 & a^{-1} y \\ 0 & a b^2 & -b^2 x \\ 0 & 0 & a^{-1} b \end{pmatrix}. \] (2.9)

In particular, the adjoint action of \(\mathbf{P}_{\text{min}}\) individually preserves the lines \(R_{\bar{e}_\alpha}\) and \(R_{\bar{e}_\beta}\) of sl\(_3/\mathfrak{p}_{\text{min}}\). Together with the relation (2.7), this shows that for \(x \in M\), the lines \(i_x^{-1}(R_{\bar{e}_\alpha})\) and \(i_x^{-1}(R_{\bar{e}_\beta})\) of \(T_x M\) do not depend on the lift \(\hat{\pi}\) of \(x\). The Cartan geometry \(\mathcal{C}\) thus induces two one-dimensional distributions \(E_\alpha^{\mathcal{C}}(x) = i_x^{-1}(R_{\bar{e}_\alpha})\) and \(E_\beta^{\mathcal{C}}(x) = i_x^{-1}(R_{\bar{e}_\beta})\) on \(M\), and the curvature of \(\mathcal{C}\) will determine when those distributions define a Lagrangian contact structure.

**Lemma 2.6.** Any torsion-free Cartan geometry \((M, \mathcal{C})\) modelled on \(G/\mathfrak{p}_{\text{min}}\) induces a Lagrangian contact structure \((E_\alpha^{\mathcal{C}}, E_\beta^{\mathcal{C}})\) on the three-dimensional base manifold \(M\).

**Sketch of proof.** For \(x \in M\), considering a local section of the Cartan bundle over \(x\), we can push down by \(\pi\) the \(\omega\)-constant vector fields \(\bar{e}_\alpha\) and \(\bar{e}_\beta\) of \(\hat{\mathcal{M}}\) (characterized by \(\omega(\bar{e}_\epsilon) \equiv e_\epsilon\)) to local vector fields \(X_\alpha\) and \(X_\beta\) of \(M\) defined on a neighbourhood of \(x\), which generate the distributions \(E_\alpha^{\mathcal{C}}\) and \(E_\beta^{\mathcal{C}}\), respectively. If \(K\) has values in \(\mathfrak{p}_{\text{min}}\), the identity \(\omega([\bar{e}_\alpha, \bar{e}_\beta]) = [e_\alpha, e_\beta] - K(e_\alpha, e_\beta)\) (deduced from Cartan’s formula for the differential of a one-form) implies easily that \([X_\alpha, X_\beta] \notin \text{Vect}(X_\alpha, X_\beta)\) in the neighbourhood of \(x\). This completes the proof.

**Remark 2.7.** In the case of the Cartan geometry of the model, it is easy to check that \((E_\alpha^{\mathcal{C}_X}, E_\beta^{\mathcal{C}_X})\) is the standard Lagrangian contact structure \(\mathcal{L}_X\) of \(X\).

### 2.3. Normal Cartan geometry of a Lagrangian contact structure.

Any three-dimensional Lagrangian contact structure is actually induced by a torsion-free Cartan geometry modelled on \(G/\mathfrak{p}_{\text{min}}\). This equivalence between three-dimensional Lagrangian contact structures and Cartan geometries modelled on \(G/\mathfrak{p}_{\text{min}}\) was discovered by Élie Cartan, who developed this notion and after whom these geometries are named.

#### 2.3.1. Equivalence problem for Lagrangian contact structures.

A given three-dimensional Lagrangian contact structure is induced by several Cartan connections, and to obtain an equivalence between both these formulations, we have to choose a particular Cartan connection. This choice will be made through a normalization condition on the
curvature. Using the basis \((\bar{e}_\alpha \wedge \bar{e}_0, \bar{e}_\beta \wedge \bar{e}_0, \bar{e}_\alpha \wedge \bar{e}_\beta)\) of \(\Lambda^2(s\ell_3/p_{\text{min}})\), we consider the following four-dimensional subspace of \(\text{End}(\Lambda^2(s\ell_3/p_{\text{min}}), s\ell_3)\):

\[
W_K = \left\{ K: \bar{e}_\alpha \wedge \bar{e}_0 \mapsto \begin{pmatrix} 0 & 0 & K^\alpha \\ 0 & 0 & K_\alpha \\ 0 & 0 & 0 \end{pmatrix}, \bar{e}_\beta \wedge \bar{e}_0 \mapsto \begin{pmatrix} 0 & K_\beta & K^\beta \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \bar{e}_\alpha \wedge \bar{e}_\beta \mapsto 0 \right\}.
\] (2.10)

The linear action of \(P_{\text{min}}\) preserves \(W_K\), which will be called the space of normal curvatures. A proof of Theorem 2.8 below can be found in [DK16, Theorem 3, p. 14] following Cartan’s method of equivalence, and in [MM20, Corollaire 4.1.5 and Proposition 4.2.2], where it is deduced from the theory of parabolic Cartan geometries developed in [ČS09, §3.1] (the reader can find an accessible and self-contained presentation of this theory of parabolic geometries in [MM20, Ch. 3]).

**Theorem 2.8.** (Cartan) [DK16, ČS09] For any Lagrangian contact structure \(L\) on a three-dimensional manifold \(M\), there exists a torsion-free Cartan geometry modelled on \(G/P_{\text{min}}\) inducing \(L\) on \(M\), whose curvature map has values in the space \(W_K\) of normal curvatures. Such a Cartan geometry is unique (up to action of principal bundle automorphisms covering the identity on \(M\)) and will be called the normal Cartan geometry of \(L\).

Furthermore, if \((M_1, L_1)\) and \((M_2, L_2)\) are two three-dimensional Lagrangian contact structures, and \(C_1\) and \(C_2\) are the associated normal Cartan geometries, then the (local) isomorphisms between \(L_1\) and \(L_2\) and the (local) isomorphism between \(C_1\) and \(C_2\) are the same. This a direct consequence of the unicity of the normal Cartan geometry. The curvature map \(K: \tilde{M} \to W_K\) of the normal Cartan geometry of a three-dimensional Lagrangian contact structure \(L\) will simply be called the curvature of \(L\).

2.3.2. **Flat Lagrangian contact structures.** The homogeneous model space \((X, L_X)\) verifies the following analogue of Liouville’s theorem.

**Theorem 2.9.** For any connected open subsets \(U\) and \(V\) of the homogeneous model space \(X\), and any diffeomorphism \(f\) from \(U\) to \(V\) that preserves its standard Lagrangian contact structure \(L_X\), there exists \(g \in G\) such that \(f\) is the restriction to \(U\) of the translation by \(g\).

**Proof.** The Maurer–Cartan form \(\omega_G\) satisfies for any tangent vectors \(v\) and \(w\) the structural equation \(d\omega_G(v, w) + [\omega_G(v), \omega_G(w)] = 0\) (see [Sha97, §3.3, p. 108]), implying that the curvature of the Cartan connection \(\omega_G\) is zero. Therefore, the curvature satisfies the normalization condition of Theorem 2.8, and \(C_X\) is a normal Cartan geometry on \(X\) modelled on \(G/P_{\text{min}}\) and associated with \(L_X\) (see Remark 2.7). Therefore, according to Theorem 2.8, any local isomorphism of \(L_X\) between two connected open subsets \(U\) and \(V\) of \(X\) lifts to a local isomorphism of the Cartan geometry \(C_X\) between \(\pi_G^{-1}(U)\) and \(\pi_G^{-1}(V)\), and such an automorphism is the left translation by an element of \(G\) according to [Sha97, Ch. 5 Theorem 5.2].
A three-dimensional Lagrangian contact structure \((M, L)\) is flat if the curvature of the normal Cartan geometry of \(L\) vanishes identically. According to the proof of Theorem 2.9, the model space is flat, and since this property is local, any Lagrangian contact structure locally isomorphic to \((X, L_X)\) is flat.

The power of Cartan geometries lies in the converse of this statement: any flat three-dimensional Lagrangian contact structure \(L\) is locally isomorphic to the homogeneous model space (see [Sha97, Theorem 5.1 and Theorem 5.2, p. 212]). There exists in this case an atlas of charts from \(M\) to \(X\) consisting of local isomorphisms of Lagrangian contact structures from \(L\) to \(L_X\), and whose transition maps are restrictions of left translations by elements of \(G\) (according to Theorem 2.9). A maximal atlas satisfying these conditions is called a \((G, X)\)-structure on \(M\). Any \((G, X)\)-structure conversely induces on \(M\) a Lagrangian contact structure \(L\) locally isomorphic to \(L_X\), whose charts are local isomorphisms from \(L\) to \(L_X\).

**Theorem 2.10.** Any flat three-dimensional Lagrangian contact structure \((M, L)\) is induced by a \((G, X)\)-structure on \(M\).

Denoting by \(\pi_M : \tilde{M} \to M\) the universal cover of \(M\), we recall that any \((G, X)\)-structure on \(M\) is described by a local diffeomorphism \(\delta : \tilde{M} \to X\) called the developing map, which is equivariant for a morphism \(\rho : \pi_1(M) \to G\) called the holonomy morphism (see, for example, [Thu97, §3.4, pp. 139–141]). Moreover for any \(g \in G\), the pair \((g \circ \delta, g \rho g^{-1})\) consisting of a developing map and holonomy morphism describes the same \((G, X)\)-structure. The Lagrangian contact structure \(L\) induced by a \((G, X)\)-structure is characterized by \(\delta^* L_X = \pi^*_M L\).

### 2.3.3. Normal generalized Cartan geometry of an enhanced Lagrangian contact structure.

Let \(S = (E^\alpha, E^\beta, E^c)\) be an enhanced Lagrangian contact structure on a three-dimensional manifold \(M\), and let \(C = (\hat{M}, \omega)\) be the normal Cartan geometry of the underlying Lagrangian contact structure \((E^\alpha, E^\beta)\). Using the isomorphisms \(i_{\hat{x}}\) defined in (2.6), the transverse distribution \(E^c\) is encoded by the map

\[\varphi : \hat{x} \in \hat{M} \mapsto i_{\hat{x}}(E^c_{\pi(\hat{x})}) \in \mathbb{V},\]

having values in the open subset

\[\mathbb{V} = \{ L \in P(\mathfrak{sl}_3/p_{\text{min}}) \mid L \not\subset \text{Vect}(\bar{e}_\alpha, \bar{e}_\beta) \}\]

of \(P(\mathfrak{sl}_3/p_{\text{min}})\). Endowing \(\mathbb{V}\) with the right \(P_{\text{min}}\)-action defined by \(L \cdot p = \text{Ad}(p)^{-1}(L)\), \(\varphi\) is \(P_{\text{min}}\)-equivariant. Conversely, any \(P_{\text{min}}\)-equivariant application \(\varphi : \hat{M} \to \mathbb{V}\) defines a transverse distribution \(E^c_{\pi(\hat{x})} = i_{\hat{x}}^{-1}(\varphi(\hat{x}))\) compatible with the Lagrangian contact structure \((E^\alpha, E^\beta)\).

**Definition 2.11.** \((C, \varphi) = (\hat{M}, \omega, \varphi)\) will be called the normal generalized Cartan geometry of the enhanced Lagrangian contact structure \(S\).
2.4. Killing fields of (enhanced) Lagrangian contact structures.

2.4.1. Some classical properties of Killing fields. A (local) Killing field of a Lagrangian contact structure \((M, \mathcal{L})\) is a (local) vector field \(X\) of \(M\) whose flow preserves \(\mathcal{L}\). The Killing fields of an enhanced Lagrangian contact structure \(\mathcal{S}\) are defined in the same way. We will denote by \(\text{Kill}(U, \mathcal{L})\) the subalgebra of Killing fields of \(\mathcal{L}\) defined on an open subset \(U \subset M\), and by \(\text{Kill}_{\mathcal{L}}^{\text{loc}}(x)\) the Lie algebra of germs of Killing fields of \(\mathcal{L}\) defined on a neighbourhood of \(x\).

The following statement summarizes important properties of Killing fields, which come from their description through Cartan geometries and are well known in this context. The results are stated for Lagrangian contact structures but are also true for enhanced Lagrangian contact structures.

**Lemma 2.12.** Let \(M\) be a three-dimensional connected manifold endowed with a Lagrangian contact structure \(\mathcal{L}\), and let \(C = (\hat{M}, \omega)\) be a normal Cartan geometry on \(M\) associated with \(\mathcal{L}\).

1. If \(\hat{f}\) is a \(\text{P}_{\text{min}}\)-equivariant diffeomorphism of \(\hat{M}\) that covers \(\text{id}_M\) and preserves \(\omega\), then \(\hat{f} = \text{id}_{\hat{M}}\). If \(\hat{X}\) is a \(\text{P}_{\text{min}}\)-invariant vector field on \(\hat{M}\) whose flow preserves \(\omega\) and whose projection on \(M\) vanishes, then \(\hat{X} = 0\). As a consequence, the lift of a local automorphism \(\hat{f}\) (respectively Killing field \(X\)) of \(\mathcal{L}\) to a \(\text{P}_{\text{min}}\)-equivariant diffeomorphism \(\hat{f}\) of \(\hat{M}\) that preserves \(\omega\) (respectively to a \(\text{P}_{\text{min}}\)-invariant vector field \(\hat{X}\) on \(\hat{M}\) whose flow preserves \(\omega\)), is unique.

2. If the lift \(\hat{X}\) of a Killing field \(X\) of \(\mathcal{L}\) vanishes at some point \(\hat{x}\), then \(X = 0\). In other words, the linear map \(X \in \text{Kill}(M, \mathcal{L}) \mapsto [X]_x \in \text{Kill}_{\mathcal{L}}^{\text{loc}}(x)\) sending a Killing field of \(\mathcal{L}\) to its germ at \(x\) is injective.

**Sketch of proof.**

1. The first assertion is a direct consequence of [ČS09, Proposition 1.5.3] for Cartan geometries modelled on \(G/P_{\text{min}}\), and implies the second one.

2. Let us assume that a local automorphism \(\hat{f}\) of \(\mathcal{C}\) fixes a point \(\hat{x} \in \hat{M}\). Then, as \(\hat{f}\) preserves the parallelism defined by \(\omega\), a classical argument implies that \(\hat{f}\) is trivial on the connected component of \(\hat{x}\). This remark easily implies the assertion about Killing fields.

3. According to [BFM09, Lemma 7.1], a local automorphism that is trivial in the neighbourhood of \(x\) is trivial on the connected component of its domain of definition that contains \(x\). This result easily implies the statement concerning Killing fields.

**Remark 2.13.** The third statement of the previous lemma shows in particular that for any connected open neighbourhood \(U\) of \(x \in M\), the dimension of \(\text{Kill}(U, \mathcal{L})\) is bounded from above by \(\dim \mathfrak{sl}_3 = 8\). Therefore, if we consider a decreasing sequence of connected open neighbourhoods \(U_i\) of \(x\) such that \(\cap_i U_i = \{x\}\), then \(\dim \text{Kill}(U_i, \mathcal{L})\) is constant for \(i\) large enough. This proves the existence of a connected open neighbourhood \(U\) of \(x\) such that

\[
X \in \text{Kill}(U, \mathcal{L}) \mapsto [X]_x \in \text{Kill}_{\mathcal{L}}^{\text{loc}}(x)
\]

is a Lie algebra isomorphism.
The following lemma is a translation of Theorem 2.9 for Killing fields of \((X, \mathcal{L}_X)\).

**Lemma 2.14.**

1. At any point \(x \in X\), the Lie algebra of local Killing fields of \(\mathcal{L}_X\) at \(x\) is identified with \(sl_3\) through the fundamental vector fields of the action. In other words, the application \(v \in sl_3 \mapsto [v^\dag]_x \in \tilde{\text{Kill}}_{\mathcal{L}_X}^{loc}(x)\) sending \(v \in sl_3\) to the germ of \(v^\dag\) at \(x\) is an anti-isomorphism of Lie algebras.

2. Any local Killing field of \((X, \mathcal{L}_X)\) defined on a connected neighbourhood of a point \(x \in X\) is the restriction of a global Killing field defined on \(X\). In other words, \(X \in \tilde{\text{Kill}}(\mathcal{L}_X) \mapsto [X]_x \in \tilde{\text{Kill}}_{\mathcal{L}_X}^{loc}(x)\) is a Lie algebra isomorphism.

*Proof.* (1) If \(v^\dag\) is trivial in the neighbourhood of \(x\), then for any \(t \in \mathbb{R}\), \(e^{tv}\) acts trivially on an open neighbourhood of \(x\). But the action of \(G\) on \(X\) is analytic: if \(g\) and \(h\) in \(G\) have the same action on some non-empty open subset of \(X\), then \(g = h\) (because the linear subspace generated by the pre-image in \(\mathbb{R}^3\) of a non-empty open subset of \(\mathbb{R}P^2\) is equal to \(\mathbb{R}^3\)). Therefore, \(e^{tv} = id\) for any \(t \in \mathbb{R}\) and \(v = 0\). The application \(v \mapsto [v^\dag]_x\) is thus injective, and as \(\dim \tilde{\text{Kill}}_{\mathcal{L}_X}^{loc}(x) \leq \dim sl_3\) according to the third assertion of Lemma 2.12, it is an isomorphism. Finally, \(v \mapsto v^\dag\) is known to be an anti-morphism of Lie algebras.

(2) Any local Killing field at \(x\) is the restriction of \(v^\dag\) for some \(v \in sl_3\) according to the first assertion and extends therefore to a Killing field defined on \(X\). \(\square\)

2.4.2. Total curvature map of an enhanced Lagrangian contact structure. Let \((\mathcal{C}, \varphi) = (\hat{M}, \omega, \varphi)\) be the normal Cartan geometry of a three-dimensional enhanced Lagrangian contact structure \((M, S)\). With \(K : M \to W_K\) as the curvature map of \(\mathcal{C}\), we define the curvature map

\[ \mathcal{K} := (K, \varphi) : \hat{M} \to W_{\mathcal{K}} := W_K \times \nabla \]

of the enhanced Lagrangian contact structure \((M, S)\), which is \(P_{\text{min}}\)-equivariant for the right diagonal action of \(P_{\text{min}}\) on \(W_{\mathcal{K}}\).

If \(W\) is any manifold endowed with a right action of \(P_{\text{min}}\), we define \(B(W) := \{(w, l) \mid w \in W, l \in \text{End}(sl_3, T_w W)\}\) (this is a vector bundle over \(W\)), which we endow with the right \(P_{\text{min}}\)-action \((w, l) \cdot p = (w \cdot p, D_w R_p \circ l \circ \text{Ad}(p))\). For any smooth \(P_{\text{min}}\)-equivariant map \(\psi : \hat{M} \to W\), we define a \(P_{\text{min}}\)-equivariant map \(D^1 \psi : \hat{M} \to B(W)\) encoding the differential of \(\psi\) as follows: \(D^1 \psi(\hat{x}) = (\psi(\hat{x}), D_{\hat{x}} \psi \circ \omega_{\hat{x}}^{-1})\). We also define inductively \(B^{k+1}(W) = B(B^k(W))\) and \(D^{k+1} \psi = D(D^k \psi) : \hat{M} \to B^{k+1}(W)\) for any \(k \in \mathbb{N}\) (with \(B^0(W) = W\) and \(D^0 \phi = \phi\)).

Denoting \(m = \dim sl_3 = 8\), we define \(W_{\mathcal{K}}^{\text{tot}} := B^m(W_{\mathcal{K}})\) and the total curvature

\[ \mathcal{K}^{\text{tot}} := D^m \mathcal{K} : \hat{M} \to W_{\mathcal{K}}^{\text{tot}} \]

of the enhanced Lagrangian contact structure \(S\). The total curvature \(\mathcal{K}^{\text{tot}}\) is \(P_{\text{min}}\)-equivariant and preserved by local automorphisms of \(S\) (that is, for any such local automorphism \(f\) we have \(\mathcal{K}^{\text{tot}} \circ f = \mathcal{K}^{\text{tot}}\)). We also define for \(k \in \mathbb{N}^*\) the space of Killing generators of order \(k\) by \(\text{Kill}^k(\hat{x}) = \omega_{\hat{x}}(\ker(D_{\hat{x}} D^{k-1} \mathcal{K})) \subset sl_3\), and the space of Killing generators of total order by \(\text{Kill}^{\text{tot}}(\hat{x}) = \text{Kill}^{m+1}(\hat{x}) = \omega_{\hat{x}}(\ker(D_{\hat{x}} \mathcal{K}^{\text{tot}})) \subset sl_3\).
2.4.3. Gromov’s theory. The integrability locus of \( \hat{M} \) is defined as the set \( \hat{M}^{\text{int}} \) of those points \( \hat{x} \in \hat{M} \) such that for any \( v \in \text{Kill}^{\text{tot}}(\hat{x}) \), there exists a local Killing field \( X \) of \( S \) defined around \( \pi(\hat{x}) \) such that \( \omega_{\hat{x}}(\hat{X}_\hat{x}) = v \). It is easy to check that \( \hat{M}^{\text{int}} \) is a \( P_{\text{min}} \)-equivariant set, and we define the integrability locus of \( M \) as \( M^{\text{int}} = \pi(\hat{M}^{\text{int}}) \).

**Theorem 2.15.** (Integrability theorem) Let \((M, S)\) be a three-dimensional enhanced Lagrangian contact structure of total curvature \( K^{\text{tot}} \), and let \( \hat{M} \) be its normal Cartan bundle. Then, the integrability locus \( \hat{M}^{\text{int}} \) of \( \hat{M} \) is equal to the set of points \( \hat{x} \in \hat{M} \) where the rank of \( D_{\hat{x}}K^{\text{tot}} \) is locally constant. In particular, \( \hat{M}^{\text{int}} \) is open and dense, and so is the integrability locus \( M^{\text{int}} \) of \( M \).

Gromov investigates in [Gro88] the integration of ‘jets’ of Killing fields for very general rigid geometric structures, and proves results related to the above theorem. In the case of three-dimensional enhanced Lagrangian contact structures, the equivalence with normal generalized Cartan geometries allows one to avoid the notion of jets of Killing fields, which is replaced by the one of Killing generators of total order. In this setting, Theorem 2.15 is a consequence of [Pec16, Theorem 4.19]. We use here a modification of the statement of Pecastaing proved by Frances in [Fra16, Theorem 2.2]. The proof of the statement of Frances for generalized Cartan geometries is straightforward, following the lines of the proof he provides for Cartan geometries, and using [Pec16, Lemmas 4.20 and 4.9].

3. Quasi-homogeneity and flatness of the structure

From now until §8.2, we are under the hypotheses of Theorem B and we adopt its notation. \( M \) is thus a three-dimensional compact connected and orientable manifold, \( S = (E^a, E^\beta, E^c) \) is an enhanced Lagrangian contact structure on \( M \), and we denote by \( L = (E^a, E^\beta) \) its underlying Lagrangian contact structure. Finally, \( f \) is an orientation-preserving automorphism of \((M, S)\) such that:

- each of the distributions \( E^a \) and \( E^\beta \) is weakly contracted by \( f \) (see Definition 1.3); and
- \( f \) has a dense orbit.

In particular, the non-wandering set \( NW(f) = NW(f^{-1}) \) equals \( M \). We recall that in this case, the set \( \text{Rec}(f) \) (respectively \( \text{Rec}(f^{-1}) \)) of recurrent points of \( f \) (respectively \( f^{-1} \)) is a dense \( G_3 \)-subset of \( M \). Therefore, \( \text{Rec}(f) \cap \text{Rec}(f^{-1}) \) is dense in \( M \) as well.

3.1. Quasi-homogeneity of the enhanced Lagrangian contact structure. At a point \( x \in M \), we introduce the subalgebra

\[
\text{is}^\text{loc}_S(x) = X \in \text{kill}^{\text{loc}}_S(x) | X(x) = 0
\]

of local Killing fields vanishing at \( x \), which we call the isotropy subalgebra of \( S \).

**Definition 3.1.** The \( \text{Kill}^{\text{loc}} \)-orbit for \( S \) (respectively \( L \)) of a point \( x \in M \) is the set of points that can be reached from \( x \) by flowing along finitely many local Killing fields.
of $S$ (respectively $L$). An enhanced Lagrangian contact structure $(M, S)$ (respectively a Lagrangian contact structure $(M, L)$) is locally homogeneous if any connected component of $M$ is a Kill$^{\text{loc}}$-orbit.

The first claim of the following proposition is a consequence of Gromov’s ‘open-dense orbit theorem’, and the second one is a reformulation in the context of enhanced Lagrangian contact structures of work by Frances in [Fra16, Proposition 5.1] for pseudo-Riemannian structures.

**Proposition 3.2.** There exists an open and dense subset $\Omega$ of $M$, such that the enhanced Lagrangian contact structure $S$ is locally homogeneous in restriction to $\Omega$. Moreover, for any $x \in \Omega$, the isotropy subalgebra $i_S^{\text{loc}}(x)$ is non-trivial.

**Proof.** Since $S$ has an automorphism $f$ with a dense orbit, Gromov’s dense orbit theorem directly implies the first claim (see [Gro88, Corollary 3.3.A] and [Pec16, Theorem 4.13] for a proof in the case of generalized Cartan geometries). Since the integrability locus $M^{\text{int}}$ is open and dense (see Theorem 2.15), and $\text{Rec}(f) \cap \text{Rec}(f^{-1})$ is dense in $M$, there finally exists a point $x \in \Omega \cap M^{\text{int}} \cap \text{Rec}(f) \cap \text{Rec}(f^{-1})$. We show now that $i_S^{\text{loc}}(x)$ is non-zero.

Let us denote by $(\tilde{M}, \omega, \varphi)$ the normal generalized Cartan geometry of $S$ (see Definition 2.11), and choose a lift $\hat{x} \in \pi^{-1}(x)$ in the Cartan bundle. Possibly replacing $f$ by $f^{-1}$, we have $\lim_{n \to +\infty} \|D_x f^n|_{E^a}\| = 0$, and by hypothesis on $x$, there exists a strictly increasing sequence $n_k$ of integers such that $f^{n_k}(x)$ converges to $x$, implying the existence of a sequence $p_k \in P_{\text{min}}$ such that $\hat{f}^{n_k}(\hat{x}) \cdot p_k^{-1}$ converges to $\hat{x}$. We claim that the sequence $\hat{f}^{n_k}(\hat{x})$ has to leave every compact subset of $\tilde{M}$, implying that $p_k$ also leaves every compact subset of $P_{\text{min}}$. In fact, if not, some subsequence $(\hat{f}^{\hat{n}_k}(\hat{x}))$ would converge in $\tilde{M}$, implying that $(\hat{f}^{\hat{n}_k})$ converges to some diffeomorphism of $\tilde{M}$ for the $C^\infty$-topology, because $\hat{f}$ preserves the parallelism defined by $\omega$ (see [Kob95, Theorem I.3.2]). Therefore, $(f^{n_k})$ would also converge for the $C^\infty$-topology to some diffeomorphism of $M$, contradicting $\lim_{k \to +\infty} \|D_x f^{n_k}|_{E^a}\| = 0$. The remainder of the proof of [Fra16, Proposition 5.1] will enable us to conclude this proof, using the total curvature $K^{\text{tot}}: \tilde{M} \to W_{K^{\text{tot}}}$ of the generalized Cartan geometry associated with $S$ (see §2.4.3). By $P_{\text{min}}$-equivariance of the total curvature and its invariance by automorphisms, $p_k \cdot K^{\text{tot}}(\hat{x}) = K^{\text{tot}}(\hat{f}^{n_k}(\hat{x}) \cdot p_k^{-1})$ converges to $K^{\text{tot}}(\hat{x})$. The manifold $W_{K^{\text{tot}}}$ has a canonical structure of algebraic variety for which the action of $P_{\text{min}}$ is algebraic (because its actions on the space $W_K$ of normal curvatures and on the algebraic variety $\mathbb{V} \subset P(\mathfrak{sl}_3/p_{\text{min}})$ are algebraic; see [Pec16, Remark 4.16] for more details). Therefore, the orbits of the action of $P_{\text{min}}$ on $W_{K^{\text{tot}}}$ are locally closed and are thus imbedded submanifolds. In particular, there exists a sequence $\varepsilon_k \in P_{\text{min}}$ converging to the identity such that $p_k \cdot K^{\text{tot}}(\hat{x}) = \varepsilon_k \cdot K^{\text{tot}}(\hat{x})$, that is, such that $\varepsilon_k^{-1} p_k \in \text{Stab}_{P_{\text{min}}} (K^{\text{tot}}(\hat{x}))$. As $\varepsilon_k^{-1} p_k$ leaves every compact subset of $P_{\text{min}}$, $\text{Stab}_{P_{\text{min}}} (K^{\text{tot}}(\hat{x})) < P_{\text{min}}$ is non-compact. But $\text{Stab}_{P_{\text{min}}} (K^{\text{tot}}(\hat{x}))$ is an algebraic subgroup of $P_{\text{min}}$ and therefore has a finite number of connected components, finally implying that its identity component is also non-compact.

Thus there exists a non-zero vector $v \in p_{\text{min}}$ in the Lie algebra of $\text{Stab}_{P_{\text{min}}} (K^{\text{tot}}(\hat{x}))$. For any $t \in \mathbb{R}$ we have by hypothesis $K^{\text{tot}}(\hat{x} \cdot \exp(tv)) = K^{\text{tot}}(\hat{x}) \cdot \exp(tv) = K^{\text{tot}}(\hat{x})$,
and deriving this equality at $t = 0$ we obtain $D_{\hat{x}}K^{\text{tot}}(\omega^{-1}(v)) = 0$, that is, $v \in \omega_{\hat{x}}(\text{Ker}(D_{\hat{x}}K^{\text{tot}})) = \text{Kill}^{\text{tot}}(\hat{x})$. As $\hat{x}$ is in the integrability locus $\hat{M}^{\text{int}}$ of $\hat{M}$, there exists a local Killing field $X \in \text{kill}^{\text{loc}}(x)$ such that $\omega_{\hat{x}}(\hat{X}) = v \neq 0$, implying in particular that $X \neq 0$ and $X(x) = 0$, that is, that $X \in \text{is}^{\text{loc}}_{S}(x) \setminus \{0\}$.

As the isotropy subalgebra at any point $y \in \Omega$ is linearly isomorphic to the one at $x$, because $\Omega$ is an Aut$^{\text{loc}}$-orbit, $\text{is}^{\text{loc}}_{S}(y)$ is finally non-zero at any point $y \in \Omega$. This completes the proof of the corollary.

3.2. Flatness of the Lagrangian contact structure. In particular, the underlying Lagrangian contact structure $\mathcal{L} = (E^\alpha, E^\beta)$ is also locally homogeneous with non-zero isotropy in restriction to the open and dense subset $\Omega$. The following result due to Tresse [Tre96] (see also [KT17, §4.5.2]) implies that $\mathcal{L}|_{\Omega}$ is flat.

**Theorem 3.3.** (Tresse) [Tre96] Any three-dimensional locally homogeneous connected Lagrangian contact structure with non-zero isotropy is flat.

By density of $\Omega$ and continuity of the curvature, the Lagrangian contact structure $(M, \mathcal{L})$ is therefore flat, and according to §2.3.2, we obtain the following.

**Corollary 3.4.** The Lagrangian contact structure $\mathcal{L}$ is described by a $(G, X)$-structure on $M$.

A self-contained proof (written in English) of Theorem 3.3 can be found in [MM20, Ch. 5, §5.3.2].

4. Local model of the enhanced Lagrangian contact structure

In the previous section, we proved that the Lagrangian contact structure $\mathcal{L}$ is locally isomorphic to the homogeneous model space $(X, \mathcal{L}_{X})$ and thus described by a $(G, X)$-structure on $M$. The classical strategy is then to reduce the possibilities for the images of the developing map $\delta: \hat{M} \to M$ and of the holonomy morphism $\rho: \pi_{1}(M) \to G$ of this structure.

In the case studied by Ghys in [Ghy87] of an Anosov flow preserving the structure, the holonomy group $\rho(\pi_{1}(M)) \subset G$ is centralized by a one-parameter subgroup of $G$, which reduces dramatically the possibilities for $\rho(\pi_{1}(M))$. But in the case of discrete-time dynamics, we do not have any relevant algebraic restriction of this kind on $\rho(\pi_{1}(M))$.

For this reason, we have to look not only at the local homogeneity of $\mathcal{L}$ on $\Omega$ but at the local homogeneity of the whole enhanced Lagrangian contact structure $S = (E^\alpha, E^\beta, E^c)$ on this open dense subset. In this section, we will show that in restriction to $\Omega$, $S$ is locally isomorphic to an infinitesimal homogeneous model that preserves a distribution transverse to the contact plane.

4.1. Two algebraic models. We begin by describing these models in an algebraic way.
4.1.1. **Left-invariant structure on SL\(_2(\mathbb{R})\).** We will use the following basis for the Lie algebra \(sl_2\) of \(SL_2(\mathbb{R})\):

\[
E = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad F = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \text{and} \quad H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.
\] (4.1)

The Lie bracket relation \([E, F] = H\) between these three vectors shows that they define a left-invariant enhanced Lagrangian contact structure \(S_{SL_2(\mathbb{R})} = (\mathbb{R} \tilde{E}, \mathbb{R} \tilde{F}, \mathbb{R} \tilde{H})\) on \(SL_2(\mathbb{R})\). Moreover, the right action of the one-parameter subgroup \(A\) generated by \(H\) preserves \(S_{SL_2(\mathbb{R})}\). We endow the universal cover \(\tilde{SL}_2(\mathbb{R})\) of \(SL_2(\mathbb{R})\) with the pullback of \(S_{SL_2(\mathbb{R})}\), so that the right action of the one-parameter subgroup \(\tilde{A}\) of \(\tilde{SL}_2(\mathbb{R})\) generated by \(H\) preserves \(S_{\tilde{SL}_2(\mathbb{R})}\).

Let \(\Gamma_0\) be a cocompact lattice of \(\tilde{SL}_2(\mathbb{R})\) and \(u : \Gamma_0 \to \tilde{A}\) a morphism whose graph-group \(\Gamma = \{(\gamma, u(\gamma)) \mid \gamma \in \Gamma_0\}\) acts freely, properly, and cocompactly on \(\tilde{SL}_2(\mathbb{R})\), via the action \((g, a) \cdot x = gxa\) (these morphisms are called *admissible* by Salein and studied in detail in his thesis [Sal99]). Then the standard structure of \(\tilde{SL}_2(\mathbb{R})\) is preserved by \(\Gamma\), and \(\Gamma \setminus \tilde{SL}_2(\mathbb{R})\) is endowed with the induced enhanced Lagrangian contact structure \(\tilde{S}\), whose distributions are exactly the invariant distributions of the algebraic contact-Anosov flow \((R_{a'})\) on \(\Gamma \setminus \tilde{SL}_2(\mathbb{R})\).

4.1.2. **Left-invariant structure on Heis(3).** We will use the following basis for the Lie algebra \(heis(3)\) of Heis(3):

\[
X = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad Z = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

According to the Lie bracket relation \([X, Y] = Z\), \(S_{\text{Heis}(3)} = (\mathbb{R} \tilde{X}, \mathbb{R} \tilde{Y}, \mathbb{R} \tilde{Z})\) is a left-invariant enhanced Lagrangian contact structure on Heis(3). The subgroup

\[
\mathcal{A} = \{ \varphi_{\lambda, \mu} \mid (\lambda, \mu) \in \mathbb{R}^{*2} \}
\]

doing automorphisms introduced in the Introduction (see (1.1)) is exactly the subgroup of \(\text{Aut}(\text{Heis}(3))\) preserving \(S_{\text{Heis}(3)}\).

Any cocompact lattice \(\Gamma\) of Heis(3) preserves \(S_{\text{Heis}(3)}\), and the quotient \(\Gamma \setminus \text{Heis}(3)\) will always be endowed with the induced enhanced Lagrangian contact structure \(S\). The invariant distributions of a partially hyperbolic affine automorphism \(L_g \circ \varphi\) of \(\Gamma \setminus \text{Heis}(3)\), with \(g \in \text{Heis}(3)\) and \(\varphi \in \mathcal{A}\), are precisely given by \(S\).

4.2. **Two homogeneous open subsets of \(X\).** The left-invariant structures of \(SL_2(\mathbb{R})\) and Heis(3) can be geometrically imbedded in \(X\) as homogeneous open subsets, which will be the local models of the enhanced Lagrangian contact structure \(S\) in restriction to \(\Omega\).
4.2.1. Some specific surfaces of $X$ and one affine chart. For $D$ a projective line of $\mathbb{RP}^2$, we define the $\beta - \alpha$ surface

$$S_{\beta,\alpha}(D) = \pi^{-1}_\alpha(D) = \bigcup_{y \in C_\beta(D)} C_\alpha(y),$$

and for $m \in \mathbb{RP}^2$, the analogous $\alpha - \beta$ surface

$$S_{\alpha,\beta}(m) = \pi^{-1}_\beta(L \in \mathbb{RP}_m) = \bigcup_{y \in C_\alpha(m)} C_\beta(y).$$

The open subset

$$\Omega_a := X \setminus S_{\beta,\alpha}([e_1, e_2])$$

of $X$, composed by pointed projective lines $(m, D)$ for which $m \notin [e_1, e_2]$, will be identified with the set $X_a$ of pointed affine lines of $\mathbb{R}^2$ as follows:

$$\phi_a: (m, D) \in \Omega_a \mapsto (m \cap P, D \cap P) \in X_a, \quad (4.2)$$

where $\text{Vect}(e_1, e_2) + (0, 0, 1)$ is identified with $\mathbb{R}^2$ by translation. The diffeomorphism $\phi_a$ is moreover equivariant for the canonical identification

$$[AX_01] \in \text{Stab}_G(\Omega_a) \mapsto A + X \in \text{Aff}(\mathbb{R}^2) \quad (4.3)$$

of $\text{Stab}_G(\Omega_a)$ with the group of affine transformations of $\mathbb{R}^2$.

4.2.2. The open subset $Y_t$. We will embed $\text{SL}_2(\mathbb{R})$ in $G$ as follows:

$$\iota: g \in \text{SL}_2(\mathbb{R}) \mapsto \begin{bmatrix} A & X \\ 0 & 1 \end{bmatrix} \in G.$$

The resulting copy $S_0$ of $\text{SL}_2(\mathbb{R})$ acts simply transitively at $o_t = ([1, 0, 1], [(1, 0, 1), e_2]) = \phi_a^{-1}(e_1 + Re_2) \in \Omega_a$, and its orbit $Y_t = S_0 \cdot o_t$ can be described as

$$Y_t = \Omega_a \setminus S_{\alpha,\beta}[e_3] = \phi_a^{-1}(\{m + L \mid m \in \mathbb{R}^2 \setminus \{(0, 0), L \in \mathbb{RP}_m\} \}.\)$$

The left-invariant structure of $\text{SL}_2(\mathbb{R})$ induces on $Y_t$ a $S_0$-invariant enhanced Lagrangian contact structure

$$\mathcal{S}_t = (\theta_{o_t} \circ \iota)_* S_{\text{SL}_2(\mathbb{R})}, \quad (4.4)$$

which is compatible with $\mathcal{L}_X$ in the sense that its $\alpha$- and $\beta$-distributions coincide with those of $\mathcal{L}_X$, and whose central distribution is entirely described by its value at $o_t$:

$$\mathcal{E}^c(o_t) = \mathbb{R}H_0^\dagger(o_t) \quad \text{where} \quad H_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \quad (4.5)$$

We denote by $A^\pm$ the subgroup of $\text{SL}_2(\mathbb{R})$ composed by diagonal matrices. The right action of $A^\pm$ preserves $\mathcal{S}_{\text{SL}_2(\mathbb{R})}$, and the direct product $\text{SL}_2(\mathbb{R}) \times A^\pm$ acts on $\text{SL}_2(\mathbb{R})$ by...
The isomorphism from $\text{SL}_2(\mathbb{R})$ to $(Y_t, S_t)$ given by the orbital map at $o_t$ is equivariant for the identification
\[
(\lambda, \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix}) \in \text{SL}_2(\mathbb{R}) \times A^\pm \mapsto \lambda g \in \text{GL}_2(\mathbb{R}).
\]
In particular,
\[
H_t := \begin{bmatrix} \text{GL}_2(\mathbb{R}) & 0 \\ 0 & 1 \end{bmatrix}
\]
is contained in the automorphism group of $(Y_t, S_t)$.

4.2.3. The open subset $Y_a$. The action of $\text{Heis}(3)$ at $o_a = ([e_3], [e_3, e_2]) = \phi_a^{-1}((0, 0) + \mathbb{R} e_2) \in \Omega_a$ is simply transitive, and its orbit $Y_a = \text{Heis}(3) \cdot o_a$ can be described as
\[
Y_a = \Omega_a \setminus \{a \in \mathbb{R}^3 | a \parallel \mathbb{R} \}.
\]
We endow $Y_a$ with the $\text{Heis}(3)$-invariant enhanced Lagrangian contact structure
\[
S_a = (\theta_{o_a})_{\text{Heis}(3)} \circ S_{\text{Heis}(3)}, \tag{4.6}
\]
which is compatible with $\mathcal{L}_X$ and whose central distribution is entirely determined by
\[
\mathcal{E}^c_a(o_a) = \mathbb{R} Z^1(o_a). \tag{4.7}
\]

Let us recall that $\mathcal{A}$ is the subgroup of automorphisms of $\text{Heis}(3)$ that moreover preserve $S_{\text{Heis}(3)}$ (see §4.1.2). The group of affine automorphisms $Lg \circ \phi$ of $\text{Heis}(3)$, where $g \in \text{Heis}(3)$ and $\phi \in \mathcal{A}$, will be seen as a semi-direct subgroup $\text{Heis}(3) \ltimes \mathcal{A}$. With this notation, the isomorphism from $(Y_a, S_a)$ to $\text{Heis}(3)$ given by the orbital map at $o_a$ is equivariant for the identification
\[
\begin{bmatrix} \lambda & x \\ 0 & \lambda^{-1} \mu^{-1} \end{bmatrix} \in \mathbb{P}_\text{min} \mapsto \left( \begin{bmatrix} \lambda & \mu x \\ 0 & \mu^{-1} y \end{bmatrix}, \phi_{\lambda^2 \mu^2 \lambda^{-1} \mu^{-2}} \right) \in \text{Heis}(3) \ltimes \mathcal{A}, \tag{4.8}
\]
and in particular, $H_a := \mathbb{P}_\text{min}$ is contained in the automorphism group of $(Y_a, S_a)$.

4.3. From the infinitesimal model to the local model. We take back the notation of Theorem B. We recall that $\pi_M : \tilde{M} \to M$ denotes the universal cover of $M$ and that $\Omega$ is a dense and open subset of $M$ where $S$ is locally homogeneous (see Proposition 3.2). We will denote $\tilde{\mathcal{S}} = \pi_M^* S = (\tilde{E}^a, \tilde{E}^\beta, \tilde{E}^c), \tilde{\Omega} = \pi_M^{-1}(\Omega)$, and $\delta : M \to X$ a developing map of the $(G, X)$-structure of $M$ describing the Lagrangian contact structure $\mathcal{L}$ (see Corollary 3.4 and §2.3.2). We finally choose for this whole section a connected component $O$ of $\tilde{\mathcal{S}}$, that is, an open Kill(locc)-orbit of $\tilde{\mathcal{S}}$.

Our goal in this section is to describe the local model of $\tilde{\mathcal{S}}$ in restriction to $O$.

4.3.1. Infinitesimal model. At any point of $X$, we will identify the Lie algebra of local Killing fields of $\mathcal{L}_X$ with $\mathfrak{s}l_3$ through the fundamental vector fields of the action of $G$ (see Lemma 2.14). Since the developing map $\delta$ is a local isomorphism from $\tilde{\mathcal{L}}$ to $\mathcal{L}_X$, it induces
at each point $x \in \tilde{M}$ an isomorphism

$$\delta^* : v \in \mathfrak{s}l_3 = \text{Kill}^{\text{loc}}_{\tilde{L}}(\delta(x)) \mapsto \delta^* v \in \text{Kill}^{\text{loc}}_{\tilde{L}}(x)$$

(4.9)

of Lie algebras, whose inverse will be denoted by $\delta_* : \text{Kill}^{\text{loc}}_{\tilde{L}}(x) \rightarrow \mathfrak{s}l_3$. For $X \in \text{Kill}^{\text{loc}}_{\tilde{L}}(x)$ and $t \in \mathbb{R}$ for which $\varphi^t_X(x)$ exists, denoting $v = \delta_* [X]_x \in \mathfrak{s}l_3$, we have

$$\delta(\varphi^t_X(x)) = e^{tv} \cdot \delta(x).$$

(4.10)

**Lemma 4.1.** There exists a subalgebra $\mathfrak{h}$ of $\mathfrak{s}l_3$ such that

$$\text{Kill}(O, \tilde{S}|O) = (\delta^* \mathfrak{h})|O = \{(\delta^* v)|_O \mid v \in \mathfrak{h}\}.$$

Moreover, any local Killing field of $\tilde{S}$ on $O$ extends to the whole $\text{Kill}^{\text{loc}}$-orbit $O$.

**Proof.** It suffices to show that the subalgebra $\mathfrak{h}(x) = \delta_* \text{Kill}^{\text{loc}}_{\tilde{S}}(x)$ is locally constant on $O$. This will in fact imply by connexity of $O$ that $\mathfrak{h}(x)$ is constant equal to some Lie subalgebra $\mathfrak{h}$ on $O$, and then $(\delta^* \mathfrak{h})|_O \subset \text{Kill}(O, \tilde{S}|O)$. But for $x \in O$, $\dim \mathfrak{h} = \dim \text{Kill}^{\text{loc}}(x) \geq \text{Kill}(O, \tilde{S}|O)$ (see Lemma 2.12), and this inclusion is thus an equality.

For any $x \in O$ there exists an open connected neighbourhood $U$ of $x$ such that any local Killing field of $\tilde{S}$ at $x$ extends to a Killing field defined on $U$ (see Remark 2.13), and for any $y \in U$ we thus have $\mathfrak{h}(x) \subset \mathfrak{h}(y)$. But $\mathfrak{h}(x)$ and $\mathfrak{h}(y)$ have the same dimension since $x$ and $y$ are in the same $\text{Kill}^{\text{loc}}$-orbit of $\tilde{S}$, and this inclusion is thus an equality. This shows that $\mathfrak{h}(x)$ is locally constant and completes the proof.

We denote from now on by $H$ the connected Lie subgroup of $G$ of subalgebra $\mathfrak{h}$. It is not necessarily closed in $G$, but the action of $H$ on $X$ is smooth for the structure of immersed submanifold of $H$.

**Lemma 4.2.** All the points of $\delta(O)$ are in the same orbit $Y$ under the action of $H$. In particular, $Y$ is open.

**Proof.** We consider $x$ and $y$ in $O$, and we want to find $h \in H$ such that $\delta(y) = h \cdot \delta(x)$. By hypothesis, as $x$ and $y$ are in the same $\text{Kill}^{\text{loc}}$-orbit of $\tilde{S}$, there exists a finite number of points $x_1 = x, \ldots, x_n = y$ such that for any $i \leq n - 1$ there exists a local Killing field $X_i$ of $\tilde{S}$ satisfying $x_{i+1} = \varphi^1_{X_i}(x_i)$. According to Lemma 4.1, there exists for each $i$ an element $v_i \in \mathfrak{h}$ such that $X_i = \delta^* v_i$, and we have $\delta(x_{i+1}) = e^{v_i} \delta(x_i)$ according to the equation (4.10), implying $\delta(y) = e^{v_1} \cdots e^{v_n} x_0 \in H \cdot \delta(x)$. 

We choose from now on a point $x \in O$, we denote $x_0 = \delta(x) \in Y$, and we consider the isotropy subalgebra

$$i = \text{stab}_h(x_0) := \{v \in \mathfrak{h} \mid v(x_0) = 0\}$$

(4.11)

of $\mathfrak{h}$ at $x_0$, characterized by $\delta^* i = i_0^{\text{loc}}(x)$. Since the orbit $Y$ of $x_0$ under $H$ is open, $\dim \mathfrak{h} - \dim i = 3$, and $i$ is non-trivial according to Proposition 3.2. We also denote $\mathcal{E}^c(x_0) = D_x \delta(\tilde{E}^c(x))$, and $h/i = D^\alpha \oplus D^\beta \oplus D^c$ the splitting sent to $T_{x_0}Y = (\mathcal{E}^\alpha \oplus \mathcal{E}^\beta \oplus \mathcal{E}^c)(x_0)$ by the isomorphism $\overline{D}_p \theta_{x_0}$ induced by the orbital map at $x_0$. 

Lemma 4.3.

1. The adjoint representation \( \overline{\text{ad}}: \mathfrak{h} \to \text{End}(\mathfrak{h}/i) \) preserves the line \( D^c \) in \( \mathfrak{h}/i \), that is, for any \( v \in \mathfrak{h} \) we have \( \overline{\text{ad}}(v)(D^c) \subseteq D^c \).

2. There exists in the neighbourhood of \( x_0 \) an unique \( H \)-invariant germ of a smooth one-dimensional distribution \( E^c \) that extends \( E^c(x_0) \) on a neighbourhood of \( x_0 \), and this distribution is everywhere transverse to \( E^a \oplus E^\beta \).

3. The developing map \( \delta \) is an isomorphism between the enhanced Lagrangian contact structures \( \tilde{S} \) and \( S_Y := (E^a, E^\beta, E^c) \), from a neighbourhood of \( x \) to a neighbourhood of \( x_0 \).

4. \( \mathfrak{h} = \tilde{\text{kill}}_{S_Y}^\text{loc}(x_0) \) and \( i = \text{is}_{S_Y}^\text{loc}(x_0) \).

5. If \( I = \text{Stab}_H(x_0) \) is a connected subgroup of \( H \), then there exists an unique \( H \)-invariant smooth one-dimensional distribution \( E^c \) that extends \( E^c(x_0) \) on the whole open orbit, \( Y \), and \( E^c \) is transverse to \( E^a \oplus E^\beta \). Furthermore, \( \delta|_O \) is a local isomorphism from \((O, \tilde{S}|_O)\) to \((Y, S_Y)\).

Proof. (1) For \( v \in \mathfrak{h} \), denoting \( X = \delta^*v \in \text{is}_{S_Y}^\text{loc}(x) \), equation (4.10) implies \( E^c(x_0) = D_{x_0}e^{tv}(E^c(x_0)) \) for any \( t \in \mathbb{R} \), and thus \( D^c = \overline{\text{Ad}}(e^{tv}) \cdot D^c = \exp(\overline{\text{ad}}(v)) \cdot D^c \). Deriving this last equality at \( t = 0 \), we obtain \( \overline{\text{ad}}(v) \cdot D^c \subseteq D^c \).

(2) The group \( I = \text{Stab}_H(x_0) \) and its identity component \( I^0 \) are closed in \( H \) for its topology of immersed submanifold, and the orbital map at \( x_0 \) induces a local diffeomorphism \( \tilde{\theta}_{x_0}: H/I^0 \to Y \), equivariant for the action of \( H \). We saw previously that \( \overline{\text{Ad}}(\exp(i)) \) preserves \( D^c \), implying that the subgroup \( \{ i \in I^0 \mid \overline{\text{Ad}}(i) \cdot D^c = D^c \} \) is equal to \( I^0 \) by connexity, that is, that \( I^0 \) preserves \( D^c \). Therefore, \( H/I^0 \) supports an unique \( H \)-invariant smooth one-dimensional distribution extending \( D^c \), which can be pushed by \( \tilde{\theta}_{x_0}: H/I^0 \to Y \), to a \( H \)-invariant distribution extending \( E^c(x_0) \) on a neighbourhood of \( x_0 \). Conversely, the pullback of any \( H \)-invariant distribution extending \( E^c(x_0) \) on a neighbourhood of \( x_0 \) is \( H \)-invariant on \( H/I^0 \), which proves the unicity of the germ of \( E^c \). As it is preserved by \( H \), it must remain transverse to \( E^a \oplus E^\beta \).

(3) For \( y \) sufficiently close to \( x \), there exists \( X \in \tilde{\text{kill}}(O, \tilde{S}|_O) \) such that \( y = \phi_X^\delta(x) \). Denoting \( y_0 = \delta(y) \) and \( v \in \mathfrak{h} \) such that \( \delta^*v = X \), we have \( D_{y_0}e^{-v} \circ D_Y\delta(\tilde{E}^c(y)) = D_X\delta \circ D_Y\phi_X^{-1}(\tilde{E}^c(y)) = E^c(x_0) \), implying \( D_Y\delta(\tilde{E}^c(y)) = E^c(y_0) \) by \( H \)-invariance of \( E^c \).

(4) This is a direct consequence of \( \delta^*\mathfrak{h} = \tilde{\text{kill}}_{\tilde{S}}^\text{loc}(x), \delta^*i = \text{is}_{\tilde{S}}^\text{loc}(x) \), and the fact that \( \delta \) is a local isomorphism from \( \tilde{S} \) to \( S_Y \) at \( x \).

(5) Concerning the first assertion, the orbital map at \( x_0 \) induces a \( H \)-equivariant diffeomorphism from \( H/I \) to \( Y \), and we saw in the proof of the second assertion that \( H/I^0 = H/I \) supports an unique \( H \)-invariant distribution extending \( D^c \) on \( H/I^0 \), which stays transverse to the contact plane.

The set \( \mathcal{E} \) of points \( y \in O \) such that \( \delta \) is a local isomorphism in the neighbourhood of \( y \) is open and non-empty, and we only have to prove that \( \mathcal{E} \) is closed to conclude the proof by connexity of \( O \). Let \( z \in O \) be an adherent point of \( \mathcal{E} \), and let us denote \( z_0 = \delta(z) \). There exists a point \( y \in \mathcal{E} \) sufficiently close to \( z \) such that for some Killing field \( X \) of \( \tilde{S} \), \( z = \phi_X^\delta(y) \). Denoting \( v \in \mathfrak{h} \) such that \( X = \delta^*v \), we have \( D_{z_0}e^{-v} \circ D_z\delta(\tilde{E}^c(z)) = D_{y_0}\delta \circ D_z\phi_X^{-1}(\tilde{E}^c(z)) = E^c(z_0) \), implying \( D_z\delta(\tilde{E}^c(z)) = E^c(z_0) \) by \( H \)-invariance of \( E^c \). By local
homogeneity of $\mathcal{S}|_O$, we can reach all the points of some neighbourhood $U$ of $z$ in $O$ by a Killing field, and the same computation as before shows that $\delta|_U$ is a local isomorphism, that is, that $z \in \mathcal{E}$.

4.3.2. Local model of an open Kill$^\text{loc}$-orbit. We will call

$$\kappa: (m, D) \mapsto (D \perp, m \perp) \in X$$

(4.12)

the flip diffeomorphism of the homogeneous model space. This involution switches the distributions $E^\alpha$ and $E^\beta$ of the standard Lagrangian contact structure, and is moreover equivariant for the Lie group morphism $\kappa_G: g \mapsto {}^t g^{-1}$ of $G$. Consequently, switching the distributions $E^\alpha$ and $E^\beta$ of the Lagrangian contact structure of $M$ is equivalent to composing the developing map $\delta$ with $\kappa$. At the level of the subalgebra $\mathfrak{h}$ introduced in the previous paragraph, it is equivalent to apply the Lie algebra morphism $D_\kappa \kappa_G = \kappa_{sl_3}: A \mapsto -{}^t A$.

Denoting

$$\begin{cases} \mathfrak{h}_t = \left\{ \begin{pmatrix} A & 0 \\ 0 & -\text{tr}(A) \end{pmatrix} \right| A \in \text{gl}_2 \right\}, \\ \mathfrak{h}_a = p_{\text{min}}, \end{cases}$$

(4.13)

we will prove in the next section the following proposition.

PROPOSITION 4.4. Up to conjugacy in $G$ or image by $\kappa_{sl_3} = -{}^t \cdot$, $\mathfrak{h}$ is equal to $\mathfrak{h}_t$ or $\mathfrak{h}_a$.

To deduce local information about $\tilde{\mathcal{S}}|_O$ from this infinitesimal classification, it only remains to look at the action of the connected Lie subgroups $H^0_t := \text{GL}^+_2(\mathbb{R})$ and $H^0_a = P^+_{\text{min}}$ of $G$, of respective Lie algebras $\mathfrak{h}_t$ and $\mathfrak{h}_a$.

PROPOSITION 4.5.

(1) $Y_t$ (respectively $Y_a$) is the only open orbit of $H^0_t$ (respectively of $H^0_a$) on $X$.

(2) $S_t$ (respectively $S_a$) is the only $H^0_t$-invariant (respectively $H^0_a$-invariant) enhanced Lagrangian contact structure of $Y_t$ (respectively $Y_a$) that is compatible with $\mathcal{L}_X$.

Proof. (1) Both of these groups are contained in $\text{Stab}_G[e_1, e_2] = \{ \begin{pmatrix} A & X \\ 0 & 1 \end{pmatrix} \mid A \in \text{GL}_2(\mathbb{R}), X \in \mathbb{R}^2 \}$, which preserves the surface $S_{\beta,\alpha}[e_1, e_2]$, and whose only open orbit is thus $\Omega_a = X \setminus S_{\beta,\alpha}[e_1, e_2]$. Any open orbit of one these groups is therefore contained in $\Omega_a$. Since $H^0_t$ preserves the surface $S_{\alpha,\beta}[e_3]$, any open orbit of $H^0_t$ is contained in $Y_t = X \setminus (S_{\beta,\alpha}[e_1, e_2] \cup S_{\alpha,\beta}[e_3]) = H^0_t \cdot o_t$. In the same way, since $H^0_a$ preserves $S_{\alpha,\beta}[e_1]$, any open orbit of $H^0_a$ is contained in $Y_a = X \setminus (S_{\beta,\alpha}[e_1, e_2] \cup S_{\alpha,\beta}[e_1]) = H^0_a \cdot o_a$.

(2) We start with $Y_t$, and we denote

$$i_t = \text{Lie}(\text{Stab}_{H^0_t}(o_t)) = \left\{ \begin{pmatrix} a & 0 & 0 \\ 0 & -2a & 0 \\ 0 & 0 & a \end{pmatrix} \right\}, \quad a \in \mathbb{R},$$
and
\[
E = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad F = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad H = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

The standard Lagrangian contact structure of \(X\) satisfies \(\mathbb{R}E^\dagger(o_t) = \mathcal{E}^\alpha(o_t)\) and \(\mathbb{R}F^\dagger(o_t) = \mathcal{E}^\beta(o_t)\), and for \(a \in \mathbb{R}\), the adjoint action of the diagonal element \([a, -2a, a]\) of \(i_t\) has the following diagonal matrix in the basis \((\tilde{E}, \tilde{F}, \tilde{H})\) of \(\mathfrak{h}/i_t\):
\[
\text{Mat}_{(\tilde{E}, \tilde{F}, \tilde{H})}(\text{ad}([a, -2a, a])) = [3a, -3a, 0].
\]

Any line \(D^c\) of \(\mathfrak{h}_t/\mathfrak{i}_t\) that is transverse to \(\text{Vect}(\tilde{E}, \tilde{F})\) has projective coordinates \([x, y, 1]\) in the basis \((\tilde{E}, \tilde{F}, \tilde{H})\) for some \((x, y) \in \mathbb{R}^2\), and \(\text{ad}([a, -2a, a])(D^c)\) is therefore generated by the vector of coordinates \((3ax, -3ay, 0)\). The only transverse line stabilized by \(\text{ad}(i_t)\) is therefore \(\mathbb{R}\tilde{H}\), and \(\mathcal{E}^c_i\) is the only \(H^0_t\)-invariant distribution of \(Y_t\) transverse to \(\mathcal{L}_X\).

Let us denote
\[
i_a = \text{Lie(Stab}_{\mathfrak{h}^2}(o_a)) = \left\{ \begin{pmatrix} a & 0 & 0 \\ 0 & -a - b & 0 \\ 0 & 0 & b \end{pmatrix} \right\}, \quad (a, b) \in \mathbb{R}^2,
\]
and
\[
X = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad Z = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\] (4.14)

We have \(\mathbb{R}X^\dagger(o_a) = \mathcal{E}^\alpha(o_a)\) and \(\mathbb{R}Y^\dagger(o_a) = \mathcal{E}^\beta(o_a)\), and for \((a, b) \in \mathbb{R}^2\), the adjoint action of the diagonal element \([a, -a - b, b]\) of \(i_a\) has the following diagonal matrix in the basis \((\tilde{X}, \tilde{Y}, \tilde{Z})\) of \(\mathfrak{p}_{\text{min}}/i_a\):
\[
\text{Mat}_{(\tilde{X}, \tilde{Y}, \tilde{Z})}(\text{ad}([a, -a - b, b])) = [2a + b, -a - 2b, a - b].
\] (4.15)

Any line \(D^c\) of \(\mathfrak{p}_{\text{min}}/i_a\) that is transverse to \(\text{Vect}(\tilde{X}, \tilde{Y})\) has projective coordinates of the form \([x, y, 1]\) in the basis \((\tilde{X}, \tilde{Y}, \tilde{Z})\) for some \((x, y) \in \mathbb{R}^2\), and \(\text{ad}([a, -a - b, b])(D^c)\) is therefore generated by the vector of coordinates \(((2a + b)x, (-a - 2b)y, a - b)\). The only transverse line stabilized by \(\text{ad}(i_a)\) is therefore \(\mathbb{R}\tilde{Z}\), and \(\mathcal{E}^c_a\) is the only \(H^0_t\)-invariant distribution of \(Y_a\) transverse to \(\mathcal{L}_X\).

We can finally describe the local geometry of \(O\), which is a connected component of \(\tilde{\Omega} = \pi^{-1}_M(\Omega)\).

**Corollary 4.6.** Up to inversion of the distributions \(E^\alpha\) and \(E^\beta\), the restriction \(\delta|_O\) of the developing map to \(O\) is a local isomorphism from \((O, \tilde{S}|_O)\) to \((Y_t, S_t)\), or to \((Y_a, S_a)\).

**Proof.** The inversion of the distributions \(E^\alpha\) and \(E^\beta\) is equivalent to applying \(\kappa_{\text{st}_{1}}\) to \(\mathfrak{h}\), and the conjugation of \(\mathfrak{h}\) by \(g \in G\) is equivalent to replacing the developing map \(\delta\) by \(g \circ \delta\) (which describes the same \((G, X)\)-structure on \(M\)). According to Proposition 4.4, we can thus assume that \(\mathfrak{h}\) is equal to \(\mathfrak{h}_t\) or \(\mathfrak{h}_a\), and the open orbit \(Y\) is therefore equal to \(Y_t\) (respectively \(Y_a\)) according to Proposition 4.5. Since the isotropy subgroups \(\text{Stab}_{H^0_t}(o_t)\)
and $\text{Stab}_{H_0}(o_a)$ are connected, there exists a $H_0^0$-invariant (respectively $H_a^0$-invariant) enhanced Lagrangian contact structure $S_Y$ on $Y$ that is compatible with $L_X$, such that $\delta|_O$ is a local isomorphism from $(O, \tilde{S}|_O)$ to $(Y, S_Y)$ (see Lemma 4.3). According to Proposition 4.5, $S_Y$ is equal to $S_t$ (respectively $S_a$).

5. Classification of the infinitesimal model

The goal of this section is to prove Proposition 4.4. Let us recall that the Lie subalgebras $i \subset h$ of $sl_3$ are characterized by $(\delta^*h)|_O = \text{Kill}(O, \tilde{S}|_O)$ and $[\delta^*i]_x = i_{\tilde{S}^x}(x)$ (see Lemma 4.1 and (4.11)).

5.1. Algebraic reduction. We first prove some purely algebraic restrictions on $h$.

**Lemma 5.1.** The dimension of $h$ is either four or five.

**Proof.** Possibly translating the developing map by an element of $G$, we can assume that $x_0 = o = ([e_1], [e_1, e_2]) \in X$, and since the adjoint action of $P_{\min}$ on the lines of $sl_3/P_{\min}$ transverse to $\text{Vect}(\tilde{e}_\alpha, \tilde{e}_\beta)$ is transitive (see (2.9)), we can moreover assume that $D_c = D_{e^\theta o}(\mathbb{R} \tilde{e}_0)$ with

$$
e_0 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

As a consequence, $i = h \cap p_{\min}$ is contained in

$$\mathcal{o} = \{v \in p_{\min} | \text{ad}(v)(\mathbb{R} \tilde{e}_0) \subset \mathbb{R} \tilde{e}_0\} = \left\{ \begin{pmatrix} a & 0 & z \\ 0 & -a-b & 0 \\ 0 & 0 & b \end{pmatrix} \bigg| (a, b, z) \in \mathbb{R}^3 \right\}. \quad (5.1)$$

Denoting

$$e^0 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \in \mathcal{o},$$

we now prove that $i \cap \mathbb{R} e^0 = \{0\}$, implying $\dim i \leq 2$ and completing the proof of the Lemma, since $i$ is non-zero and $\dim h - \dim i = 3$.

Let us assume by contradiction that $e^0 \in i$. As $h + p_{\min} = sl_3$ (because the orbit of $o$ under $H$ is open), there exists $v \in h$ and $w \in p_{\min}$ such that

$$e_\beta = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} = v + w.$$

But $[v, e^0] \in h$, and $[w, e^0] \in \mathbb{R} e^0 \subset i$ since $w \in p_{\min}$, finally implying that

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} = [e_\beta, e^0] = [v, e^0] + [w, e^0] \in h \cap p_{\min} = i \subset \mathcal{o},$$

which contradicts the description of $\mathcal{o}$ in (5.1).
Let
\[ \mathfrak{h} = \mathfrak{s} \ltimes_{\phi} \mathfrak{r} \]  
be the Levi decomposition of \( \mathfrak{h} \), where \( \mathfrak{s} \) is a semi-simple subalgebra of \( \mathfrak{h} \) (or is trivial if \( \mathfrak{h} \) is solvable), \( \mathfrak{r} \) is the solvable radical of \( \mathfrak{h} \) (an ideal of \( \mathfrak{h} \)), and \( \phi \) is the restriction of the adjoint representation \( \text{ad} : \mathfrak{h} \to \text{Der} \mathfrak{h} \) (\( \phi : \mathfrak{s} \to \text{Der} \mathfrak{r} \) describes the bracket in \( \mathfrak{h} \) by \([v, w] = \phi(v)(w) \) for \( v \in \mathfrak{s} \) and \( w \in \mathfrak{r} \)).

A proper semi-simple subalgebra of \( \mathfrak{s} \mathfrak{l}_3 \) of dimension less than five is three-dimensional and is thus isomorphic to \( \mathfrak{s} \mathfrak{l}_2 \) or to \( \mathfrak{s} \mathfrak{o}(3) \). Moreover, up to conjugacy in \( \text{SL}_3(\mathbb{R}) \), the only embedding of \( \mathfrak{s} \mathfrak{o}(3) \) in \( \mathfrak{s} \mathfrak{l}_3 \) is the inclusion, and the only embeddings of \( \mathfrak{s} \mathfrak{l}_2 \) in \( \mathfrak{s} \mathfrak{l}_3 \) are

\[
\mathfrak{s}_0 := \left\{ \begin{pmatrix} A & 0 \\ 0 & 0 \end{pmatrix} \bigg| A \in \mathfrak{s} \mathfrak{l}_2 \right\} \quad \text{and} \quad \mathfrak{s} \mathfrak{o}(1, 2). \tag{5.3}
\]

If \( \mathfrak{h} \) is not solvable, \( \mathfrak{s} \) is thus equal to \( \mathfrak{s}_0 \), \( \mathfrak{s} \mathfrak{o}(1, 2) \), or \( \mathfrak{s} \mathfrak{o}(3) \) up to conjugacy in \( \text{SL}_3(\mathbb{R}) \). The centralizers of these subalgebras in \( \mathfrak{s} \mathfrak{l}_3 \) are

\[
\left\{ \begin{array}{l}
\mathcal{C}_{\mathfrak{s} \mathfrak{l}_3}(\mathfrak{s} \mathfrak{o}(1, 2)) = \mathcal{C}_{\mathfrak{s} \mathfrak{l}_3}(\mathfrak{s} \mathfrak{o}(3)) = [0], \\
\mathcal{C}_{\mathfrak{s} \mathfrak{l}_3}(\mathfrak{s}_0) = \left\{ \begin{pmatrix} x & 0 & 0 \\ 0 & x & 0 \\ 0 & 0 & -2x \end{pmatrix} \bigg| x \in \mathbb{R} \right\}
\end{array} \right. \tag{5.4}
\]

**Lemma 5.2.** Up to conjugacy in \( \text{SL}_3(\mathbb{R}) \) or image by \( \kappa_{\mathfrak{s} \mathfrak{l}_3} = -^t \cdot \), we have the following results.

1. If \( \mathfrak{h} \) is not solvable, then
   a. \( \mathfrak{s} \) is equal to \( \mathfrak{s}_0 \); and
   b. \( \mathfrak{h} \) is equal to \( \mathfrak{h}_1 \) or to
   \[
   \mathfrak{h}_1 = \mathbb{R}^2 \ltimes \mathfrak{s} \mathfrak{l}_2 = \left\{ \begin{pmatrix} A & X \\ 0 & 0 \end{pmatrix} \bigg| A \in \mathfrak{s} \mathfrak{l}_2, X \in \mathbb{R}^2 \right\}. \tag{5.5}
   \]

2. If \( \mathfrak{h} \) is solvable, then \( \mathfrak{h} \) is either contained in \( \mathfrak{h}_0 = \mathfrak{p}_{\text{min}} \), or equal to
   \[
   \mathfrak{h}_2 = \mathbb{R}^2 \ltimes \text{sim}(\mathbb{R}^2) = \left\{ \begin{pmatrix} A & X \\ 0 & -\text{tr} \ A \end{pmatrix} \bigg| A \in \text{sim}(\mathbb{R}^2), X \in \mathbb{R}^2 \right\}, \tag{5.6}
   \]
   where \( \text{sim}(\mathbb{R}^2) = \left\{ \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \bigg| (a, b) \in \mathbb{R}^2 \right\} \).

**Proof.** (1a) Let us assume for a contradiction that \( \mathfrak{s} \) is conjugated to \( \mathfrak{s} \mathfrak{o}(1, 2) \) or \( \mathfrak{s} \mathfrak{o}(3) \), implying that \( \mathcal{C}_{\mathfrak{s} \mathfrak{l}_3} \mathfrak{s} = \{0\} \) according to (5.4). Since \( \mathfrak{s} \) is simple, if the Lie algebra morphism \( \phi \) is not injective then it is trivial, implying \( \mathfrak{r} \subset \mathcal{C}_{\mathfrak{s} \mathfrak{l}_3} \mathfrak{s} = \{0\} \) and thus \( \dim \mathfrak{h} = \dim \mathfrak{s} = 3 \), which contradicts Lemma 5.1. Our hypothesis on \( \mathfrak{s} \) implies therefore that \( \phi \) is injective, and in particular that \( \dim \text{Der} \mathfrak{r} \geq \dim \mathfrak{s} = 3 \).

Since \( \dim \mathfrak{s} = 3 \), the solvable radical \( \mathfrak{r} \) is of dimension one or two according to Lemma 5.1 and is thus isomorphic to \( \mathbb{R} \), \( \text{aff}(\mathbb{R}) \), or \( \mathbb{R}^2 \). But if \( \mathfrak{r} \) is isomorphic to \( \mathbb{R} \) or \( \text{aff}(\mathbb{R}) \), then \( \text{Der} \mathfrak{r} \) is of dimension one or two, which contradicts the injectivity of \( \phi \), and \( \mathfrak{r} \) is thus isomorphic to \( \mathbb{R}^2 \). Since \( \mathfrak{s} \mathfrak{o}(3) \) has no non-zero two-dimensional representation, this implies that \( \mathfrak{s} \) is conjugated to \( \mathfrak{s} \mathfrak{o}(1, 2) \). The connected Lie subgroup \( H \) of \( \text{SL}_3(\mathbb{R}) \) of
Lie algebra $\mathfrak{h}$ then contains $SO^0(1, 2)$, and its adjoint action thus induces by restriction a two-dimensional representation $\phi$ of $SO^0(1, 2)$ on $\tau$ (because $\tau$ is an ideal of $\mathfrak{h}$). Since $SO^0(1, 2)$ is isomorphic to $PSL_2(\mathbb{R})$, $\phi$ is trivial, implying that $\phi$ is trivial as well, which contradicts the injectivity of $\phi$. Finally, $s$ is conjugated to $s_0$.

(1b) Let us assume by contradiction that $\tau$ is isomorphic to $\text{aff}(\mathbb{R})$. Then $\text{Der} \ \tau$ is two-dimensional and $\phi$ is thus non-injective, that is, trivial by simplicity of $s_0$. But $\tau$ is then contained in the centralizer of $s_0$, which is one-dimensional according to (5.4), contradicting the original hypothesis. Therefore, $\tau$ is isomorphic to $\mathbb{R}^2$ or $\mathbb{R}$.

We first assume that $\tau$ is isomorphic to $\mathbb{R}^2$, implying that $\phi$ is injective (otherwise $\tau \subset C_{\mathfrak{sl}_3} s_0$, which is one-dimensional). We use the linear mapping $ev_{e_3}|\tau : M \in \tau \mapsto M(e_3) \in \mathbb{R}^3$ and discuss according to the dimension of its image $\tau(e_3)$. We emphasize that $\tau$ is normalized by the connected Lie subgroup $S_0$ of $SL_3(\mathbb{R})$ of Lie algebra $s_0$, and that $\tau(e_3)$ is thus preserved by $S_0$. If $\tau(e_3)$ is a plane then $\tau(e_3) = \text{Vect}(e_1, e_2)$ since it is preserved by $S_0$, and $ev_{e_3}|\tau$ is moreover injective. There exists $v \in \tau$ such that $ev_{e_3}(v) = e_1$, and with $A = (1 0 \lambda) \in \mathfrak{sl}_2$ and $u = (A 0 0) \in s_0$ we have $ev_{e_3}([u, v]) = e_1 = ev_{e_3}(v)$. This implies $[u, v] = v$ by injectivity of $ev_{e_3}|\tau$ and, finally,

$$v = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & x & 0 \end{pmatrix}$$

for some $x \in \mathbb{R}$. The same reasoning with $w \in \tau$ such that $ev_{e_3}(w) = e_2$ and $A = (-1 0 1) \in \mathfrak{sl}_2$ implies that

$$w = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ y & 0 & 0 \end{pmatrix}$$

for some $y \in \mathbb{R}$. Since $\tau$ is abelian we have $[v, w] = 0$, which implies $x = y = 0$ and proves that $\tau = (0 0 \mathbb{R}^2)$, that is, that $\mathfrak{h} = \mathbb{R}^2 \rtimes \mathfrak{sl}_2$. If $\tau(e_3) = \{0\}$, then $p|\tau$ is injective, implying $p(\tau) = \mathbb{R}^2$. Therefore, $\dim(\kappa_{\mathfrak{sl}_3}(\tau))(e_3) = 2$, which brings us back to the first case, and $\kappa_{\mathfrak{sl}_3}(h) = \mathbb{R}^2 \rtimes \mathfrak{sl}_2$. Finally, $\dim(\tau(e_3)) = 1$ is impossible. Otherwise, $\tau' = \ker ev_{e_3} \cap \tau$ is one-dimensional, and since $p : (B 0 0) \in \tau' \mapsto X \in \mathbb{R}^2$ is injective (because $\tau \cap s_0 = \{0\}$), $p(\tau')$ is a line of $\mathbb{R}^2$. But for $w \in \tau'$ and $v = (A 0 0) \in s_0$ we have $p([v, w]) = -p(w)A$, that is, $p(\tau')$ is preserved by $\mathfrak{sl}_2$ and cannot be a line.

We now assume that $\tau$ is isomorphic to $\mathbb{R}$. Then $\phi$ is non-injective and thus trivial, implying $\tau \subset C_{\mathfrak{sl}_3} s_0$. This inclusion is an equality by equality of dimensions, proving $\mathfrak{h} = \mathfrak{h}_\tau$.

(2) As $\mathfrak{h}$ is solvable, it preserves a complex line in $\mathbb{C}^3$ according to Levi’s theorem. More precisely, either $\mathfrak{h}$ preserves a real line, or it preserves a plane on which it acts by similarities. The second case implies $\mathfrak{h} \subset \mathbb{R}^2 \rtimes \text{sim}(\mathbb{R}^2) = \mathfrak{h}_2$ up to conjugacy in $SL_3(\mathbb{R})$. In the first case we can assume that $\mathfrak{h}$ preserves $\mathbb{R}e_1$, and if the representation $(\begin{smallmatrix} 0 & A \\ \bar{A} & \bar{0} \end{smallmatrix}) \in \mathfrak{h} \mapsto A \in \mathfrak{gl}_2$ also preserves a real line, then $\mathfrak{h} \subset p_{\text{min}} = \mathfrak{h}_a$ up to conjugacy. If not, then $\kappa_{\mathfrak{sl}_3}(\mathfrak{h}) \subset \{(-1 0 A) | A \in \text{sim}(\mathbb{R}^2), X \in \mathbb{R}^2\}$, according to the same remark as before. As this last subalgebra is conjugated to $\mathbb{R}^2 \rtimes \text{sim}(\mathbb{R}^2) = \mathfrak{h}_2$, this concludes the proof of the lemma.
5.2. Two further properties of the infinitesimal model. We now prove two further properties of the infinitesimal model \((h, i)\), in order to eliminate the ‘exotic’ cases \(h_1\) and \(h_2\) that appeared in the algebraic classification of Lemma 5.2.

**Lemma 5.3.** Let \(l\) be a subalgebra of \(\mathfrak{sl}_3\) containing \(h\), let \(j = \text{stab}_1(x_0)\) be the isotropy at \(x_0\), and let \(D^c\) be the line of \(l/j\) sent to \(E^c(x_0)\) by the orbital map at \(x_0\). If \(\overline{\text{ad}}(j)(D^c) \subset D^c\), then \(l = h\).

**Proof.** Let us denote by \(L\) the connected subgroup of \(G\) of Lie algebra \(l\), and by \(J^0\) the identity component of \(J = \text{Stab}_L(x_0)\). As \(\overline{\text{ad}}(j)\) preserves \(D^c\), \(\overline{\text{Ad}}(\exp(j))\) preserves \(D^c\), and the subgroup of elements \(j \in J^0\) such that \(\overline{\text{Ad}}(j)\) preserves \(D^c\) is thus equal to \(J^0\) by connexity. The construction made in the second assertion of Lemma 4.3 is thus valid for \(L/J^0\) and proves the existence of an unique \(L\)-invariant enhanced Lagrangian contact structure \(S'_Y\) extending \((E^u(x_0), E^\beta(x_0), E^c(x_0))\) in the neighbourhood of \(x_0\). As \(h \subset l\), \(H \subset L\), and \(S'_Y\) is thus \(H\)-invariant, implying \(S'_Y = S_Y\) by the unicity of such a structure. Therefore, \(l \subset \mathfrak{t}^\text{loc}_{S_Y}(x_0) = h\), which concludes the proof. \(\square\)

**Lemma 5.4.** Let us assume that \(i\) is one-dimensional, and let \(v\) be a non-zero element of \(i\). Then the eigenvalues of \(\overline{\text{ad}}(v) \in \text{End}(h/i)\) with respect to the eigenlines \(D^\alpha\) and \(D^\beta\) are non-zero.

**Proof.** We already know that \(\overline{\text{ad}}(i)\) is diagonalizable with eigenlines \(D^\alpha\), \(D^\beta\), and \(D^c\) (see Lemma 4.3). The proof is the same for the eigenvalues of both eigenlines \(D^\alpha\) and \(D^\beta\), and so we only show it for \(D^\alpha\). By density of \(\text{Rec}(f) \cap \text{Rec}(f^{-1})\) in \(M\) (see the introduction of §3), there exists \(x \in O\) such that \(\bar{x} = \pi_M(x) \in \text{Rec}(f) \cap \text{Rec}(f^{-1})\), and possibly replacing \(f\) by \(f^{-1}\), we have \(\lim_{n \to +\infty} ||D_{\bar{x}}f^n|_{E^\alpha(\bar{x})}||_M = 0\) for a given Riemannian metric that we fix on \(M\).

By hypothesis on \(\bar{x}\), there exists a sequence \((\gamma_k)\) in \(\pi_1(M)\) and a strictly increasing sequence \((n_k)\) of integers such that \(\gamma_k f^{n_k}(x)\) converges to \(x\), and we can moreover assume up to extraction that \(x_k \in O\) for any \(k\), implying that \(\gamma_k f^{n_k}\) preserves \(O\). Endowing \(M\) with the pullback \(\bar{\mu}_M\) of the Riemannian metric of \(M\), we have \(\lim_{k \to +\infty} ||D_{\bar{x}}(\gamma_k f^{n_k})|_{E^\alpha(\bar{x})}\|_{\bar{\mu}_M} = 0\) (since \(\pi_1(M)\) acts by isometries).

Liouville’s Theorem 2.9 for the homogeneous model space \((X, L_X)\) implies the existence of a unique sequence \((g_k)\) in \(G\) satisfying

\[
\delta \circ \gamma_k f^{n_k} = g_k \circ \delta \quad \text{on a neighbourhood of } x. \tag{5.7}
\]

Denoting \(x_0 = \delta(x)\), \(g_k \cdot x_0 = \delta \circ \gamma_k f^{n_k}(x) \in Y = H \cdot x_0\) converges to \(x_0\), and there thus exists a sequence \(h_k \in H\) converging to the identity in \(G\) such that \(h_k \cdot x_0 = g_k \cdot x_0\). Since \(\delta\) is a local isomorphism from \(\tilde{S}\vert_O\) to \(S_Y\) on a neighbourhood of \(x\), equation (5.7) defining \(g_k\) shows that \(g_k\) preserves \(S_Y\) on a neighbourhood of \(x_0\). By \(H\)-invariance of \(S_Y\), \(i_k = h_k^{-1} g_k\) also preserves \(S_Y\), and \(i_k\) is thus contained in the closed subgroup

\[I := \{i \in \text{Stab}_G(x_0) \mid i \text{ preserves } S_Y \text{ on a neighbourhood of } x_0\}\]

of \(G\). The Lie algebra of \(I\) is equal to \(i\) because \(i_{S_Y}^{\text{loc}}(x_0) = i\) (see Lemma 4.3).
FACT. \( I = \{ i \in \text{Stab}_G(x_0) \mid \text{Ad}(i) \cdot h = h \text{ and } \overline{\text{Ad}}(i) \cdot D^c = D^c \}. \) In particular \( I \) is algebraic and has a finite number of connected components.

**Proof.** For \( i \in I \) and \( v \in h \), the relation \( D_{x_0} i \circ D_{e} \theta_{x_0} = D_{e} \theta_{x_0} \circ \text{Ad}(i) \) implies \( i^{-1}^* v^\dagger = (\text{Ad}(i) \cdot v)^\dagger \). Since \( i \) is a local automorphism of \( S_Y \) and \( v^\dagger \) is a Killing field of \( S_Y \), \( (\text{Ad}(i) \cdot v)^\dagger \) is also a Killing field of \( S_Y \), implying \( \text{Ad}(i) \cdot v \in h \) since \( \text{Stab}_{S_Y}(x_0) = h \) (see Lemma 4.3). Moreover, \( D_{x_0} i(\mathcal{E}_{X_0}^c) = \mathcal{E}_{x_0}^c \) implies \( \overline{\text{Ad}}(i) \cdot D^c = D^c \).

Let us conversely assume that \( i \in \text{Stab}_G(x_0) \) satisfies \( \text{Ad}(i) \cdot h = h \) and \( \overline{\text{Ad}}(i) \cdot D^c = D^c \). We consider \( v \in h \) sufficiently close to 0, such that with \( h = e^v \in H \) and \( y = h \cdot x_0 \in Y \), \( S_Y \) is defined at \( y \). Since \( \overline{\text{Ad}}(i) \cdot D^c = D^c \), \( D_{x_0} L_i(\mathcal{E}_c(x_0)) = \mathcal{E}_c(x_0) \), and \( h' := i h^{-1} = e^{\text{Ad}(i) \cdot v} \in H \) because \( \text{Ad}(i) \cdot h = h \). By \( H \)-invariance of \( \mathcal{E}_c \), we obtain \( D_{y} i(\mathcal{E}_c(y)) = D_{x_0} h' \circ D_{x_0} i(\mathcal{E}_c(x_0)) = \mathcal{E}_c(i \cdot y) \), proving that \( i \in I \).

We can thus assume up to extraction that \( (i_k) \) lies in a given connected component of \( I \), and there then exists \( g \in I \) such that \( j_k = g i_k \) is contained in the identity component \( I^0 \). We endow \( X \) with a Riemannian metric \( \mu_X \), and denote by \( \tilde{\mu}_X = \delta^* \mu_X \) its pullback on \( \tilde{M} \). Since \( (\gamma_k f^h)(x) \) is relatively compact in \( \tilde{M} \), the metrics \( \tilde{\mu}_M \) and \( \tilde{\mu}_X \) are equivalent in restriction to \( (\gamma_k f^h)(x) \), and the limit stated above for \( \tilde{\mu}_M \) is thus valid for \( \tilde{\mu}_X \), implying \( \lim ||D_{x_0} g_k|_{\mathcal{E}^c}(x_0)||_{\mu_X} = 0 \). As \( j_k = g h_k^{-1} g_k \) with \( (g h_k^{-1}) \) relatively compact in \( G \), we also have \( \lim ||D_{x_0} j_k|_{\mathcal{E}^c}(x_0)||_{\mu_X} = 0 \).

As \( I^0 \) is connected and one-dimensional, there exists a non-zero \( v \in i \) and a sequence \( t_k \in \mathbb{R} \) such that \( i_k = \exp(t_k v) \), implying that \( D_{x_0} j_k \) is conjugated by the orbital map to \( \exp(t_k \tilde{\text{ad}}(v)) \), and thus \( \lim \| \exp(t_k \tilde{\text{ad}}(v)) \|_{D^\alpha} = 0 \). Denoting by \( \lambda_\alpha \) the eigenvalue of \( \tilde{\text{ad}}(v) \) with respect to \( D^\alpha \), \( \exp(t_k \tilde{\text{ad}}(v)) \|_{D^\alpha} = \exp(\lambda_\alpha t_k) \|_{D^\alpha} \) then implies \( \lambda_\alpha \neq 0 \).

5.3. *End of the classification.* We now put into our analysis the geometrical and dynamical properties of \( h \) proved above.

**Lemma 5.5.** \( h_1 = \mathbb{R}^2 \times sl_2 \) does not satisfy the geometrical conditions of Lemma 4.3.

**Proof.** The only open orbit of the connected Lie subgroup \( H_1 \) of \( G \) of Lie algebra \( h_1 \) is the open subset \( \Omega_{\alpha} \) defined in §4.2.1. If \( H_1 \cdot x_0 \) is open for some point \( x_0 \in X \), we can thus assume that \( x_0 = ([e_3], [e_3, e_1] \in \Omega_{\alpha} \) up to conjugacy in \( H_1 \), implying that \( i_1 = \text{Lie}(\text{Stab}_{H_1}(x_0)) = \{ (a \ b \ c) \in \mathbb{R}^2 \}.\) Denoting \( v_\alpha = (0 \ 0 \ 0) \) and \( v_\beta = (1 \ 0 \ 0) \), we have \( v_\alpha(X_0) = \mathcal{E}^\alpha(X_0) \) and \( v_\beta(X_0) = \mathcal{E}^\beta(X_0) \), and defining \( v_c = (1 \ 0 \ 0) \) and \( i = (0 \ 1 \ 0) \in i_1 \), the matrix of \( \tilde{\text{ad}}(i) \) in the basis \( (\tilde{v}_\alpha, \tilde{v}_\beta, \tilde{v}_c) \) of \( h_1/i_1 \) is

\[
\text{Mat}_{(\tilde{v}_\alpha, \tilde{v}_\beta, \tilde{v}_c)} \tilde{\text{ad}}(i) = \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0
\end{pmatrix}.
\]

Any line of \( h_1/i_1 \) that is transverse to \( \text{Vect}(\tilde{v}_\alpha, \tilde{v}_\beta) \) has projective coordinates \( [a, b, 1] \) in the basis \( (\tilde{v}_\alpha, \tilde{v}_\beta, \tilde{v}_c) \) for some \( (a, b) \in \mathbb{R}^2 \), and \( \tilde{\text{ad}}(i)(D^c) \) thus has coordinates \( [0, 1, 0] \). This proves that \( \tilde{\text{ad}}(i)(D^c) \not\subset D^c \), that is, that \( h_1 \) does not satisfy the geometrical conditions of Lemma 4.3.
LEMMA 5.6. If \( \mathfrak{h} \) is a four-dimensional subalgebra of \( \mathfrak{h}_a = \mathfrak{p}_{\min} \) or is equal to \( \mathfrak{h}_2 = \mathbb{R}^2 \times \text{Sim}(\mathbb{R}^2) \), then \( \mathfrak{h} \) does not respect both the geometrical conditions of Lemma 4.3 and the dynamical condition of Lemma 5.4.

Proof. We first assume that \( \mathfrak{h} \) is a four-dimensional subalgebra of \( \mathfrak{p}_{\min} \). Therefore, \( H \subset \mathfrak{p}_{\min} \), and if \( H \cdot x_0 \) is open then \( x_0 \in \mathfrak{Y}_a \) according to Proposition 4.5. We can thus assume up to conjugacy in \( H \) that \( x_0 = o_a = (\{e_3\}, \{e_3, e_2\}) \in \mathfrak{Y}_a \), implying that

\[
i = \text{stab}(o_a) \subset i_a = \text{stab}_{\mathfrak{p}_{\min}}(o_a) = \left\{ \begin{pmatrix} a & 0 & 0 \\ 0 & -a - b & 0 \\ 0 & 0 & b \end{pmatrix} \mid (a, b) \in \mathbb{R}^2 \right\}.
\]

Let \( D^c \subset \mathfrak{h}/i \) be a line preserved by \( \text{ad}(i) \), such that \( D^c \) is transverse to \( (E^c \oplus E^d) \). Since \( \mathfrak{h} \) is a proper subalgebra of \( \mathfrak{p}_{\min} \), Lemma 5.3 implies that \( \text{ad}(i_a)(D^c) \not\subset D^c \), and thus that \( \text{stab}_{i_a}(D^c) = \{ v \in i_a \mid \text{ad}(v)(D^c) \subset D^c \} = i \) is one-dimensional. Any line \( D^c \) of \( \mathfrak{p}_{\min}/i_a \) which is transverse to the contact plane has projective coordinates \([x, y, 1]\) in the basis \((\bar{X}, \bar{Y}, \bar{Z})\) of \( \mathfrak{p}_{\min}/i_a \), for some \((x, y) \in \mathbb{R}^2\) (see Proposition 4.6), and according to (4.15) we have:

- if \( x = y = 0 \), that is, \( D^c = \mathbb{R}\bar{Z} \), then \( \text{stab}(\mathbb{R}\bar{Z}) = i_a \);
- if \( x = 0 \) and \( y \neq 0 \), that is, \( D^c = D^c_Y(t) := \mathbb{R}(\bar{Z} + t\bar{Y}) \) for some \( t \in \mathbb{R} \), then \( \text{stab}_{i_a}(D^c_Y(t)) \) is equal to the line \( i_Y \) generated by the diagonal matrix

\[
[1, 1, -2] = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix};
\]

- if \( x \neq 0 \) and \( y = 0 \), that is, \( D^c = D^c_X(t) := \mathbb{R}(\bar{Z} + t\bar{X}) \) for some \( t \in \mathbb{R} \), then \( \text{stab}_{i_a}(D^c_X(t)) \) is equal to the line \( i_X \) generated by the diagonal matrix

\[
[-2, 1, 1] = \begin{pmatrix} -2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix};
\]

- if \( x \neq 0 \) and \( y \neq 0 \), then \( \text{stab}_{i_a}(D^c) = \{0\} \).

The only transverse lines with a one-dimensional stabilizer being \( D^c_X(t) \) and \( D^c_Y(t) \), \( i \) is equal to \( i_X \) or \( i_Y \). But \( \text{Mat}_{(\bar{X}, \bar{Y}, \bar{Z})} \text{ad}([1, 1, -2]) = [0, 3, 3] \) and \( \text{Mat}_{(\bar{X}, \bar{Y}, \bar{Z})} \text{ad}([-2, 1, 1]) = [-3, 0, -3] \) according to (4.15), that is, the elements of \( i_X \) and \( i_Y \) have zero eigenvalue with respect to either the \( \alpha \) or the \( \beta \)-direction, proving that \( \mathfrak{h} \) does not satisfy the dynamical condition of Lemma 5.4.

In the same way, if \( \mathfrak{h} = \mathfrak{h}_2 \), then we can assume that \( x_0 = o_a \in \Omega_a \) up to conjugacy in \( H_2 = \mathbb{R}^2 \times \text{Sim}(\mathbb{R}^2) \), implying \( i_2 = \text{stab}_{\mathfrak{h}_2}(o_a) = i_Y \) as defined above. We saw that the elements of \( i_Y \) have zero eigenvalue with respect to the \( \alpha \)-direction, proving that \( \mathfrak{h}_2 \) does not satisfy the dynamical condition of Lemma 5.4.

Proposition 4.4 now directly follows from Lemmas 5.2, 5.5, and 5.6.
6. Global structure

From the local model that we determined for the enhanced Lagrangian contact structure \( \mathcal{S} \), we will now deduce some global information.

6.1. Local homogeneity of the enhanced Lagrangian contact structure. So far, we only have information on a dense and open subset \( \Omega \) of \( M \) (see Propositions 3.2 and 4.6). The first step to obtain global information is to prove the following.

**Proposition 6.1.** The open dense subset \( \Omega \) equals \( M \), that is, \( \mathcal{S} \) is locally homogeneous on \( M \).

We will denote in this subsection by \((\mathcal{C}, \varphi) = (\hat{M}, \omega, \varphi)\) the normal generalized Cartan geometry of the enhanced Lagrangian contact structure \( \hat{S} = \pi^* M S \) of \( \hat{M} \), and by \( K^{\text{tot}} : \hat{M} \rightarrow W K^{\omega} \) its total curvature (see §§ 2.3.3 and 2.4.2). We recall that \( \hat{\Omega} = \pi^* M^{-1}(\Omega) \subset \hat{M} \), and that the projection of the Cartan bundle is denoted by \( \pi : \hat{M} \rightarrow \hat{M} \).

We also recall that the local homogeneity of \( \hat{S}|_\hat{\Omega} \) means that the connected components of \( \hat{\Omega} \) are exactly its \( \text{Kill}^{\text{loc}} \)-orbits (see Definition 3.1). Since the rank of \( D K^{\text{tot}} \) is invariant by the right action of \( \mathfrak{p}_{\text{min}} \) and by the flow of Killing fields, this shows that \( \text{rk}(D K^{\text{tot}}) \) is constant over any connected component of \( \hat{\Omega} \).

We choose for this whole subsection a connected component \( O \) of \( \hat{\Omega} \) (that is, a \( \text{Kill}^{\text{loc}} \)-orbit of \( \hat{S} \)) such that \( \text{rk}(D K^{\text{tot}}) \) for \( \hat{x} \in \pi^{-1}(O) \) is maximal among \( \text{rk}(D K^{\text{tot}}) \) for \( \hat{x} \in \pi^{-1}(\hat{\Omega}) \). We will denote by \((Y, S_Y)\) the local model of \( \hat{S}|_O \), equal to \((Y_t, S_t)\) or \((Y_a, S_a)\), such that \( \delta|_O : (O, \hat{S}|_O) \rightarrow (Y, S_Y) \) is a local isomorphism (see Corollary 4.6).

We still denote by \( h \) the subalgebra of Killing fields of \( S_Y \), respectively equal to \( h_t \) or \( h_a \) (see Proposition 4.4), and by \( H \) the corresponding Lie connected subgroup

\[
H^0_t = \begin{bmatrix} \text{GL}_2^+(\mathbb{R}) & 0 \\ 0 & 1 \end{bmatrix} \quad \text{or} \quad H^0_a = \mathfrak{p}_{\text{min}}^+.
\]

of \( G \) of Lie algebra \( \mathfrak{h} \), preserving \( S_Y \).

We recall that \( \delta : \hat{M} \rightarrow X \) denotes the developing map of the \((G, X)\)-structure of \( M \) describing the flat Lagrangian contact structure \( \mathcal{L} \) (see Proposition 3.4).

**Lemma 6.2.** The boundary of \( O \) is mapped to \( X \setminus Y \) by the developing map \( \delta(\partial O) \subset X \setminus Y \).

**Proof.** Let us assume by contradiction that there exists \( x \in \partial O \) such that \( x_0 = \delta(x) \in Y \). The pullback \( \hat{h} := \delta^* \mathfrak{h} = \{ \delta^* v : v \in \mathfrak{h} \} \) is a subalgebra of vector fields on \( \hat{M} \), such that \( \delta \text{Kill}(O, \hat{S}|_O) = \hat{h}|_O \) according to Lemma 4.1. As \( x_0 \in Y \), there exists an open and convex neighbourhood \( W_0 \) of \( 0 \) in \( h \) such that \( V = \exp(W_0) \cdot x_0 \subset Y \) is an open neighbourhood of \( x_0 \). Denoting \( W = \delta^* W_0 \subset h, U = \{ \varphi_X^t(x) : X \in W \} \) is thus an open neighbourhood of \( x \), and possibly shrinking \( W_0 \), we can moreover assume that \( \delta|_U \) is a diffeomorphism from \( U \) to \( V \). As \( x \in \partial O \), there exist \( y \in U \cap O \) and \( X \in W \) such that \( x = \varphi_X^t(y) \), implying that \( \varphi_X^t(y) \in U \) for any \( t \in [0 ; 1] \), and thus \( \delta(\varphi_X^t(y)) \in V \subset Y \). Denoting \( \inf_{t \in [0 ; 1]} \varphi_X^t(y) \in \partial O \), \( t_0 > 0 \) because \( O \) is open, and \( \varphi_X^t(y) \in \partial O \) because \( \partial O \) is closed.
Replacing \( x \) by \( \phi_t^0(y) \) and \( X \) by \((X/t_0)\) in \( W \), we finally have \( y \in O \), \( x = \phi_t^1(y) \in \partial O \), and for any \( t \in [0;1[ \), \( \phi_t^1(y) \in O \) with \( X|_{O} \in \text{Kill}(O, \hat{S}|_{O}) \).

Choosing \( \hat{y} \in \pi^{-1}(y) \), the invariance of \( D^1K^{\text{tot}} \) by local automorphisms and the fact that \( \phi_t^1 \) is a local automorphism of \((C, \varphi)\) on the neighbourhood of \( y \) for any \( t \in [0;1[ \), imply \( D^1K^{\text{tot}}(\phi_t^1(\hat{y})) = D^1K^{\text{tot}}(\hat{y}) \) for any \( t \in [0,1[ \). Denoting \( \hat{x} = \phi_t^1(\hat{y}) \), we obtain \( D^1K^{\text{tot}}(\hat{x}) = D^1K^{\text{tot}}(\hat{y}) \) by continuity, that is, \( K^{\text{tot}}(\hat{x}) = K^{\text{tot}}(\hat{y}) \) and \( D_\hat{x}K^{\text{tot}} \circ \omega_{\hat{x}}^{-1} = D_\hat{y}K^{\text{tot}} \circ \omega_{\hat{y}}^{-1} \).

This implies \( \hat{x} \in \hat{M}^{\text{int}} \). In fact as the rank of \( D\hat{x}K^{\text{tot}} \) can only increase locally, there is an open neighbourhood \( U \) of \( \hat{x} \) where the rank of \( D\hat{x}K^{\text{tot}} \) is greater than \( \text{rk}(D_\hat{x}K^{\text{tot}}) \). Let us assume for a contradiction that the open subset of \( U \) where \( \text{rk}(D_\hat{x}K^{\text{tot}}) \) is constant on the open neighbourhood \( U \) of \( \hat{x} \), proving that \( \hat{x} \in \hat{M}^{\text{int}} \) according to the integrability theorem (Theorem 2.15).

As the Kill loc-orbit \( O \) of \( y \) is open, \( \omega_{\hat{y}}^{-1}(p_{\text{min}}) + \text{Ker}(D_\hat{y}K^{\text{tot}}) = T_\hat{y}\hat{M} \), and therefore \( \omega_{\hat{x}}^{-1}(p_{\text{min}}) + \text{Ker}(D_\hat{x}K^{\text{tot}}) = T_\hat{x}\hat{M} \) because \( D_\hat{x}K^{\text{tot}} \circ \omega_{\hat{x}}^{-1} = D_\hat{y}K^{\text{tot}} \circ \omega_{\hat{y}}^{-1} \). Since \( \hat{x} \in \hat{M}^{\text{int}} \), for any \( v \in \text{Ker}(D_\hat{x}K^{\text{tot}}) \) there is a local Killing field \( X \) of \( \hat{S} \) defined in the neighbourhood of \( X \) such that \( \hat{x}_t = v \). But \( \omega_{\hat{x}}^{-1}(p_{\text{min}}) + \text{Ker}(D_\hat{x}K^{\text{tot}}) = T_\hat{x}\hat{M} \), and we thus have \( \{X \mid X \in \text{Kill}^{\text{loc}}(\hat{S}) \} = T_\hat{x}\hat{M} \), implying that the Kill loc-orbit of \( x \) is open. Since \( x \in \partial O \), the Kill loc-orbit of \( x \) intersects thus the Kill loc-orbit \( O \), that is, \( x \in O \), which contradicts our initial hypothesis. This contradiction concludes the proof of the lemma.

Lemma 6.2 allows us to reduce the study of the central direction \( \tilde{E}^c \) on the boundary of \( O \) to the study of the central direction \( E^c \) on the boundary of \( Y \). We first present some geometrical remarks about the open subsets \( Y_\alpha \) and \( Y_\beta \) of \( X \), defined in §§4.2.2 and 4.2.3.

Let us recall that, denoting \( D_{\infty} = [e_1, e_2] \), \( m_\epsilon = [e_3] \), and \( m_\alpha = [e_1] \), we have
\[
Y_\beta = X \setminus (S_{\beta,\alpha}(D_{\infty}) \cup S_{\alpha,\beta}(m_\epsilon)) \quad \text{and} \quad Y_\alpha = X \setminus (S_{\beta,\alpha}(D_{\infty}) \cup S_{\beta,\alpha}(m_\alpha)).
\]
In particular, for \( \epsilon = \alpha \) and \( \tau \) we have: \( X \setminus Y_\tau = \partial Y_\epsilon = S_{\beta,\alpha}(D_{\infty}) \cup S_{\alpha,\beta}(m_\tau) \). We define in both cases
\[
G := \{ x \in \partial Y \mid C^\alpha(x) \not\subseteq \partial Y \text{ or } C^\beta(x) \not\subseteq \partial Y \}.
\]
It is easy to check that for \( \epsilon = \alpha \) and \( \tau \), we have
\[
G_\epsilon = \partial Y_\epsilon \setminus \{C^\beta(D_{\infty}) \cup C^\alpha(m_\epsilon) \cup (S_{\beta,\alpha}(D_{\infty}) \cap S_{\alpha,\beta}(m_\tau))\},
\]
and that for any \( x \in G \), if \( C^\epsilon(x) \not\subseteq \partial Y \) for \( \epsilon = \alpha \) or \( \beta \), then \( C^\epsilon(x) \setminus \{x\} \subset Y \).

We have \( S_{\beta,\alpha}(D_{\infty}) \cap S_{\alpha,\beta}(m_\alpha) = C^\beta(D_{\infty}) \cup S_{\beta,\alpha}(m_\alpha) \), and \( S_{\beta,\alpha}(D_{\infty}) \cap S_{\alpha,\beta}(m_\epsilon) \) is equal to the chain defined by \( (m_t, D_{\infty}) \), denoted by \( C(m_t, D_{\infty}) \) and defined as follows:
\[
C(m_t, D_{\infty}) := \{[m, [m, m_t]] \mid m \in D_{\infty}\}.
\]
Finally, we will use the following description of the respective orbits of \( H \) on \( G \):
(1) the orbits of $H^0_t$ on $G_t$ are $G^1_t = S_{\alpha, \beta}(m_t) \setminus (C^\alpha(m_t) \cup C(m_t, D_\infty))$ where $C^\alpha(x) \setminus \{x\} \subset Y_t$, and $G^2_t = S_{\beta, \alpha}(D_\infty) \setminus (C^\beta(D_\infty) \cup C(m_t, D_\infty))$ where $C^\beta(x) \setminus \{x\} \subset Y_t$;

(2) the orbits of $H^0_a$ on $G_a$ are $G^1_a = S_{\alpha, \beta}(m_a) \setminus (C^\alpha(m_a) \cup C^\beta(D_\infty))$ where $C^\alpha(x) \setminus \{x\} \subset Y_a$ and $G^2_a = S_{\beta, \alpha}(D_\infty) \setminus (C^\alpha(m_a) \cup C^\beta(D_\infty))$ where $C^\beta(x) \setminus \{x\} \subset Y_a$.

We will now prove that the central direction $E^c$ degenerates along the $\alpha$- and $\beta$-circles when converging to a point of $G$.

**Lemma 6.3.** Let $\gamma : [0 ; 1] \to X$ be a smooth path such that $\gamma([0 ; 1]) \subset Y$, $x = \gamma(0) \in G$, and $\gamma([0 ; 1])$ is entirely contained in $C^\alpha(x)$ or entirely contained in $C^\beta(x)$. Then $E^c(\gamma(t))$ converges at $t = 0$ to a line contained in $(E^\alpha \oplus E^\beta)(x)$.

**Proof.** As the action of $H$ on $Y$ preserves $E^c$, it will be sufficient to prove this result for one point of each of the two orbits of $H$ on $G$ described above, in each of the two cases $Y_t$ and $Y_a$. We thus have only four cases to handle, and we saw that in each case, either $C^\alpha(x) \setminus \{x\} \subset Y$ and $C^\beta(x) \subset \partial Y$, or the contrary. We thus have only one possibility to consider for $\gamma$ in each of these four cases, either that $\gamma([0 ; 1]) \subset C^\alpha(x)$, or that $\gamma([0 ; 1]) \subset C^\beta(x)$. To clarify our strategy, let $x$ be a point of $G^\mu_t$ for $\mu = t$ or $a$ and $i = 1$ or 2, and let us consider the following data:

- a one-parameter subgroup $\{g^i_t\}_{t \in \mathbb{R}}$ of $G$ such that, denoting $x(t) = g^i_t \cdot x$, we have $\{x(t) | t \in \mathbb{R}\} = C^c(x) \setminus \{y\}$, with $y \in C^\epsilon(x) \cap Y$, and $\epsilon = \alpha$ or $\beta$ according to the case considered;

- a one-parameter subgroup $\{h^i_t\}_{t \in \mathbb{R}}$ of $H$ such that $g^i_t \cdot x = x(t) = h^{r-1}t \cdot y$ for any $t \in \mathbb{R}^*$;

- $A$ in $\mathfrak{s}_3$ such that $D_x \theta_y (\mathbb{R}A) = E^c(y)$, where $\theta_y : G \to X$ is the orbital map at $y$; and

- $g_0 \in G$ such that $g_0 \cdot x = o$, where $o = ([e_1], [e_1, e_2])$ is the usual base-point of $X$.

For any $t \in \mathbb{R}^*$, we have $D_{x(t)}(g_0 g^{-i} t \cdot A) = D_x \theta_y (\mathbb{R} A (g_0 g^{-i} t h^{r-1} \cdot A))$. Then $D_{x(t)}(G \mathbb{R} A (g_0 g^{-i} t h^{r-1} \cdot A)) \subset T_x X$ converges to a line $L \subset (E^\alpha \oplus E^\beta)(o)$, and as $g^i g_0^{-1}$ converges to $g_0^{-1}$ at $t = 0$, we deduce by continuity that $E^c(x(t))$ converges at $t = 0$ to $D_0 g_0^{-1}(L)$, contained in $(E^\alpha \oplus E^\beta)(x)$, because $g_0^{-1}$ preserves $E^\alpha \oplus E^\beta$.

In conclusion, we only have to find, in each of the four cases $\mu = t$ or $a$ and $i = 1$ or 2, a point $x \in G^\mu_i$, together with $g^i, h^i, A$, and $g_0$ satisfying the above conditions, and to prove that $p(\mathbb{R} A (g_0 g^{-i} t h^{r-1} \cdot A))$ converges at $t = 0$ to a line contained in $\mathbb{R}(\epsilon_\alpha, \epsilon_\beta)$.

We begin with $Y_t$, for which we choose for both orbits $G^1_t$ and $G^2_t$ the point $y : = o_t = ([1, 0, 1], [(1, 0, 1), e_2]) \in Y_t$. Let us recall that in this case,

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

satisfies $E^c(o_t) = D_x \theta_{o_t}(\mathbb{R} A)$ (see §4.2.2).
For $G^1_t$, choosing $x = ([1, 0, 1], [(1, 0, 1), e_1]) = ([1, 0, 1], [e_1, e_3]),$

$$g_0 = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix},$$

and the one-parameter subgroups

$$g^t = \begin{pmatrix} 1 & 0 & 0 \\ t & 1 & -t \\ 0 & 0 & 1 \end{pmatrix}$$

of $G$ and

$$h^t = \begin{pmatrix} 1 & t & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

of $H^0_t$ such that $g^t \cdot x = h^{t^{-1}} \cdot e_t \in C^\alpha(x)$, we obtain

$$\text{Ad}(g_0 g^{-t} h^{t^{-1}}) \cdot A = \begin{pmatrix} 1 & -2 & -2t^{-1} \\ t & 1 & -2t^{-1} \\ -t & t & 1 \end{pmatrix},$$

and thus $p(\mathbb{R} \text{ Ad}(g_0 g^{-t} h^{t^{-1}}) \cdot A)$ converges at $t = 0$ to $\mathbb{R} \tilde{e}_\beta$.

For $G^2_t$, choosing $x = ([e_2], [e_2, (1, 0, 1)],$

$$g_0 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 1 & 0 & -1 \end{pmatrix},$$

and the one-parameter subgroups

$$g^t = \begin{pmatrix} 1 & t & 0 \\ 0 & 1 & 0 \\ 0 & t & 1 \end{pmatrix}$$

of $G$ and

$$h^t = \begin{pmatrix} 1 & 0 & 0 \\ t & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
of $H^0_t$ such that $g' \cdot x = h' \cdot o_t \in C^{\beta}(x)$, we obtain

$$\text{Ad}(g_0g^{-t}h^{-1}) \cdot A = \begin{pmatrix} 1 & 2t^{-1} & 0 \\ 0 & -1 & 0 \\ t & 1 & 0 \end{pmatrix},$$

and thus $p(\mathbb{R} \text{ Ad}(g_0g^{-t}h^{-1}) \cdot A)$ converges at $t = 0$ to $\mathbb{R} \tilde{e}_a$.

We now consider the case of $Y_a$, for which we choose for both orbits $G^1_a$ and $G^2_a$ the point $y := o_a = ([e_3], [e_3, e_2]) \in Y_a$, and we recall that in this case

$$A = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

satisfies the above condition $E^c(o_a) = D_e\theta_{o_a}(\mathbb{R}A)$ (see §4.2.3).

- For $G^1_a$, choosing $x = ([e_3], [e_3, e_1])$,

$$g_0 = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

and the one-parameter subgroups

$$g' = \begin{pmatrix} 1 & 0 & 0 \\ t & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

of $G$ and

$$h' = \begin{pmatrix} 1 & t & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

of $H^0_a$ such that $g' \cdot x = h' \cdot o_a \in C^{\alpha}(x)$, we obtain

$$\text{Ad}(g_0g^{-t}h^{-1}) \cdot A = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ -t & 0 & 0 \end{pmatrix},$$

and thus $p(\mathbb{R} \text{ Ad}(g_0g^{-t}h^{-1}) \cdot A)$ converges at $t = 0$ to $\mathbb{R} \tilde{e}_\beta$.

- For $G^2_a$, choosing $x = ([e_2], [e_2, e_3])$,

$$g_0 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}.$$
and the one-parameter subgroups

\[
g' = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & t & 1 \end{pmatrix}
\]

of \( G \) and

\[
h' = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & t \\ 0 & 0 & 1 \end{pmatrix}
\]

of \( H^0_\alpha \) such that \( g' \cdot x = h'^{-1} \cdot o_a \in C^\beta(x) \), we obtain

\[
\text{Ad}(g_0g^{-t}h'^{-1}) \cdot A \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ t & 1 & 0 \end{pmatrix},
\]

and thus \( p(\mathbb{R} \text{ Ad}(g_0g^{-t}h'^{-1}) \cdot A) \) converges at \( t = 0 \) to \( \mathbb{R} \tilde{e}_a \).

According to the discussion above, this concludes the proof of the lemma. \( \square \)

We are now able to prove Proposition 6.1.

**Proof of Proposition 6.1.** Let us assume by contradiction that \( \Omega \neq M \). We choose a connected component \( O \) of \( \tilde{\Omega} \) such that the rank of \( D_{\tilde{x}}K^\text{tot} \) for \( \tilde{x} \in \pi^{-1}(O) \) is maximal among the ranks of \( D_{\tilde{x}}K^\text{tot} \) for \( \tilde{x} \in \pi^{-1}(\tilde{\Omega}) \). As \( \emptyset \neq O \neq \tilde{M} \) by hypothesis, there exists \( x \in \partial O \), and as \( \tilde{E}^\alpha \oplus \tilde{E}^\beta \) is contact, \([\text{Sus73}, \text{Theorem 4.1}]\) implies the existence of a piecewise smooth path \( \gamma : [0 ; 1] \rightarrow \tilde{M} \) constituted by a finite concatenation of segments of \( \alpha \)- and \( \beta \)-leaves, joining \( x = \gamma(1) \) to a point \( y = \gamma(0) \in O \). Denoting \( t_0 = \inf\{t \in [0 ; 1] \mid \gamma(t) \in \partial O\} \), \( t_0 > 0 \) and \( \gamma(t_0) \in \partial O \). Replacing \( x \) by \( \gamma(t_0) \), keeping only the last smooth arc of \( \gamma \), replacing \( y \) by the origin of this arc, and choosing a parametrization of this arc by \([0 ; 1]\), we finally end with a smooth path \( \gamma : [0 ; 1] \rightarrow \tilde{M} \) such that \( \gamma([0 ; 1]) \subset O \), \( x = \gamma(1) \in \partial O \), and \( \gamma([0 ; 1]) \) is entirely contained in the same \( \alpha \)- or \( \beta \)-leaf. The proof being the same in the two cases, we assume that \( \gamma([0 ; 1]) \subset \tilde{F}^\alpha(x) \) to fix the ideas.

Denoting \( x_0 = \delta(x), x_0 \in X \setminus Y \) according to Lemma 6.2, and \( \delta(\gamma([0 ; 1])) \subset Y \) because \( \delta(O) \subset Y \) (see Lemma 4.2). Finally, \( \delta(\gamma([0 ; 1])) \) is an open interval of \( C^\alpha(x_0) \) contained in \( Y \), and \( x_0 \in X \setminus Y \), that is, \( x_0 \in \mathcal{G} \). Denoting \( \gamma_0(t) = \delta(\gamma(t)) \), Lemma 6.3 implies therefore that \( \mathcal{E}^c(\gamma_0(t)) \) converges to a line \( D_0^c \subset (\mathcal{E}^\alpha \oplus \mathcal{E}^\beta)(x_0) \) at \( t = 1 \). As \( \delta|_O \) is a local isomorphism between \( S|_O \) and \( S_Y \), we have \( \tilde{E}^c(\gamma(t)) = (D_{\gamma(t)}\delta)^{-1}(\mathcal{E}^c(\gamma_0(t))) \) for any \( t \in [0 ; 1[ \), implying \( \tilde{E}^c(x) = (D_{\delta}\delta)^{-1}(D_0^c) \) by continuity. Since \( \delta \) is a local isomorphism between the Lagrangian contact structures \( \tilde{L} \) and \( L_X \), this implies that \( \tilde{E}^c(x) \subset (\tilde{E}^\alpha \oplus \tilde{E}^\beta)(x) \), which contradicts the definition of the transverse distribution \( \tilde{E}^c \). This contradiction concludes the proof of the proposition. \( \square \)
6.2. Reduction of the holonomy group. We first describe the global and local automorphisms of the models \((Y_t, S_t)\) and \((Y, S_a)\).

**Proposition 6.4.**

1. The following equalities hold:

\[
\text{Aut}(Y_t, S_t) = H_t = \begin{bmatrix} GL_2(\mathbb{R}) & 0 \\ 0 & 1 \end{bmatrix}
\]

and \(\text{Aut}(Y, S_a) = H_a = P_{\text{min}}\).

2. Let \((Y, S_Y)\) be one of the two models \((Y_t, S_t)\) and \((Y, S_a)\). Then any local isomorphism of \(S_Y\) between two connected open subsets of \(Y\) is the restriction of the action of a global automorphism of \(\text{Aut}(Y, S_Y)\).

**Proof.**

1. The inclusions \(H_t \subset \text{Aut}(Y_t, S_t)\) and \(H_a \subset \text{Aut}(Y, S_a)\) were explained in §§4.2.2 and 4.2.3. Since the automorphism groups are contained in the stabilizers of the open subsets, the equalities follow because \(H_t = \text{Stab}_G(Y_t)\) and \(H_a = \text{Stab}_G(Y_a)\).

2. Let us emphasize that \(\text{Aut}(Y, S_Y)\) is precisely the normalizer of \(h\) in \(G\). Let \(\varphi\) be a local automorphism of \(S_Y\) between two connected open subsets \(U\) and \(V\) of \(Y\). For any \(v \in h\), since \(v|_V\) is a Killing field of \(S_Y\), \(\varphi^*(v|_V)\) is a Killing field of \(S_Y\), and therefore \(\varphi^*(v|_V) = w|_U\) for some \(w \in h\). But \(\varphi\) is in particular a local automorphism of the Lagrangian contact structure \(L_X\) of \(X\), and is thus the restriction to an open subset \(U \subset Y\) of the left translation by an element \(g \in G\), according to Theorem 2.9. Therefore, \(w|_U = \varphi_* (v|_V) = (\text{Ad}(g) \cdot v)|_U\), implying that \(\text{Ad}(g) \cdot v = w \in h\) since the action of \(G\) is analytic (see Lemma 2.14). Consequently, \(g \in \text{Nor}_G(h) = \text{Aut}(Y, S_Y)\).

Let us recall that \(\rho : \pi_1(M) \to G\) denotes the holonomy morphism associated with the developing map \(\delta : M \to X\) of the \((G, X)\)-structure of \(M\) (see Corollary 3.4 and §2.3.2).

**Proposition 6.5.** The holonomy group \(\rho(\pi_1(M))\) is contained in \(\text{Aut}(Y, S_Y)\). Consequently, \(M\) has either a \((H_t, Y_t)\)-structure or a \((H_a, Y_a)\)-structure, and its developing map is a local isomorphism of enhanced Lagrangian contact structures from \(\tilde{S}\) to \(S_t\) (respectively \(S_a\)).

**Proof.** According to Proposition 6.1, \(S\) is locally homogeneous, and we thus deduce from Proposition 4.6 that up to interversion of the distributions \(E^\alpha\) and \(E^\beta\), the developing map \(\delta\) of the \((G, X)\)-structure of \(M\) can be chosen to be a local isomorphism from \((\tilde{M}, \tilde{S})\) to one of the two models \((Y_t, S_t)\) and \((Y_a, S_a)\). According to Proposition 6.4, proved for these two models, the holonomy morphism has moreover values in the corresponding automorphism group \(H_t\) (respectively \(H_a\)) described in the same result, and \(M\) is finally endowed with a \((H_t, Y_t)\)-structure (respectively \((H_a, Y_a)\)-structure). Concerning the interversion of \(E^\alpha\) and \(E^\beta\), it is easy to construct for both models, \((Y_t, S_t)\) and \((Y_a, S_a)\), a diffeomorphism of \(Y\) interverting the distributions \(E^\alpha\) and \(E^\beta\) and fixing the transverse distribution \(E^\gamma\). In other words, for both these models, the structures \((E^\alpha, E^\beta, E^\gamma)\) and \((E^\beta, E^\alpha, E^\gamma)\) are isomorphic, so that \textit{a posteriori}, the order of the distributions \(E^\alpha\) and \(E^\beta\) in the statement of Proposition 6.5 does not matter.
7. Completeness of the structure
We will denote by \((\mathcal{H}, Y)\) the local model of \(S\), which is either \((H_t, Y_t)\) or \((H_a, Y_a)\), and by \(\delta: \tilde{M} \to Y\) and \(\rho: \pi_1(M) \to \mathcal{H}\) the developing map and holonomy morphism of the \((\mathcal{H}, Y)\)-structure of \(M\). The goal of this section is to prove the following.

**Proposition 7.1.** The developing map \(\delta\) is a covering map from \(\tilde{M}\) to \(Y\).

It is a known fact that a local diffeomorphism satisfying the path-lifting property is a covering map (the reader can, for example, find a proof in [DC76, §5.6, Proposition 6, p. 383]). According to the following statement, it will actually be sufficient to prove the path-lifting property in the \(\alpha, \beta\), and central directions to prove that \(\delta\) is a covering map.

**Lemma 7.2.** Let \(h: N \to B\) be a local diffeomorphism between two smooth three-dimensional manifolds, \(B\) being connected. We assume that there is a smooth splitting \(E_1 \oplus E_2 \oplus E_3 = TB\) of the tangent bundle of \(B\) into three one-dimensional smooth distributions, such that for any \(i \in \{1, 2, 3\}, x \in \text{Im}(h)\), and \(\tilde{x} \in h^{-1}(x)\), any path tangent to \(E_i\) and starting from \(x\) entirely lifts through \(h\) to a path starting from \(\tilde{x}\). Then \(h\) is a covering map from \(N\) to \(B\) (and, in particular, \(h\) is surjective).

**Proof.** Since \(h\) is a local diffeomorphism, it suffices to prove that our hypothesis implies the lift of any path. By compactness, it is sufficient to locally lift the paths in \(B\), around any point. We choose \(x \in B\) and a sufficiently small open neighbourhood \(U\) of \(x\), such that there are three smooth vector fields \(X, Y, Z\) generating \(E_1, E_2, E_3\) on \(U\), and \(\epsilon > 0\) such that \((t, u, v) \in ]-\epsilon; \epsilon[^3 \mapsto \phi(t, u, v) := \phi_X^t \circ \phi_Y^u \circ \phi_Z^v(x) \in U\) is well defined and is a diffeomorphism (this exists according to the inverse mapping theorem). Let us choose \(\tilde{x} \in h^{-1}(x)\). Then, denoting by \(\tilde{X} = h^*X, \tilde{Y} = h^*Y, \) and \(\tilde{Z} = h^*Z\) the pullbacks, the property of path-lifting in the directions \(E_1, E_2, E_3\), from any point, implies that \(\tilde{\phi}(t, u, v) := \phi_X^t \circ \phi_Y^u \circ \phi_Z^v(\tilde{x})\) is well defined on \([-\epsilon; \epsilon[^3\). If \(\gamma: [0; 1] \to U\) is a continuous path starting from \(x\) and contained in \(U\), there are three continuous maps \(t, u, v\) from \([0; 1]\) to \([-\epsilon; \epsilon]\) such that \(\gamma(s) = \phi(t(s), u(s), v(s))\). Since \(h \circ \tilde{\phi} = \phi\) by construction, \(\tilde{\gamma}(s) := \tilde{\phi}(t(s), u(s), v(s))\) is then a lift of \(\gamma\) starting from \(\tilde{x}\), which completes the proof. \(\square\)

**Remark 7.3.** In our case, proving that the paths in \(\delta(\tilde{M})\) in the \(\alpha\)-direction (respectively \(\beta\) or central direction) lift to \(\tilde{M}\) is equivalent to proving that for any \(x \in \delta(\tilde{M})\) and \(\tilde{x} \in \delta^{-1}(x)\), we have the following equality:

\[
\delta(\tilde{F}^{\alpha}(\tilde{x})) = \mathcal{C}^{\alpha}(x) \cap \delta(\tilde{M})
\]

(respectively the same equality for \(\beta\)-leaves and circles, or for central leaves).

We start by proving that the image of any \(\alpha\) (respectively \(\beta\)) leaf in \(\tilde{M}\) misses exactly one point in the associated \(\alpha\)-circle (respectively \(\beta\)-circle). We recall that \(\partial Y = X \setminus Y\), as explained before Lemma 6.3.
Lemma 7.4. For any $\tilde{x} \in \tilde{M}$, denoting $x = \delta(\tilde{x})$, there exists $x^* \in C^\beta(x) \cap \partial Y$ such that $\delta(\tilde{F}^\beta(\tilde{x})) = C^\beta(x) \setminus \{x^*\} = C^\beta(x) \cap Y$. The same happens for $\alpha$-leaves and their associated $\alpha$-circles.

Proof. We will only present the proof for $\beta$-leaves and $\beta$-circles as in the statement, the case of the $\alpha$-direction being the same. Denoting $\tilde{x} = \pi_M(\tilde{x})$, and possibly replacing $f$ by $f^{-1}$, we have $\lim_{n \to +\infty} \|D\tilde{F}^n\|_M = 0$ for some fixed Riemannian metric on $M$.

The description of the open subsets $Y_1$ and $Y_a$ in §§ 4.2.2 and 4.2.3 easily shows that in both these cases, the intersection of any $\beta$-circle (respectively $\alpha$-circle) with $Y$ misses exactly one point of the circle. In other words, the intersection $C^\beta(x) \cap \partial Y$ is a single point $\{x^*\}$ and, as a consequence, $\delta(\tilde{F}^\beta(\tilde{x})) \subset C^\beta(x) \setminus \{x^*\} = C^\beta(x) \cap Y$. To complete the proof of the lemma, we only have to prove that $\delta(\tilde{F}^\beta(\tilde{x}))$ cannot miss more than one point of $C^\beta(x)$. To achieve this, we assume by contradiction that there exists $x^- \neq x^+ \in C^\beta(x) \setminus \{x, x^*\}$ such that

$$\delta(\tilde{F}^\beta(\tilde{x})) = \{x^- \} \cup \{x^+\} \subseteq C^\beta(x) \setminus \{x^*\},$$

(7.1)

where $\{x^- \} \cup \{x^+\}$ is the connected component of $C^\beta(x) \setminus \{x^-, x^+\}$ that contains $x$.

Since $M$ is compact, there exists a strictly increasing sequence $(n_k)$ of positive integers such that, denoting $\tilde{x} = \pi_M(\tilde{x})$, $\tilde{x}_{\infty} = f^{n_k}(\tilde{x})$ converges to a point $\tilde{x}_{\infty} \in M$, and as $M = \pi_1(M) \setminus \tilde{M}$, there furthermore exists a sequence $\gamma_k \in \pi_1(M)$ such that $\tilde{x}_{\infty} = \gamma_k \cdot f^{n_k}(\tilde{x})$ converges to a lift $\tilde{x}_{\infty}$ of $\tilde{x}_{\infty}$. As $\gamma_k f^{n_k}$ is an automorphism of the Lagrangian contact structure $\tilde{L}$, and $\delta$ is a local isomorphism from $\tilde{L}$ to $L_X$, Theorem 2.9 implies the existence of a unique sequence $g_k \in G$ satisfying

$$\delta(\gamma_k \cdot f^{n_k}(\tilde{x})) = g_k \cdot \delta(\tilde{x}).$$

We denote $x_k = \delta(\tilde{x}_{\infty}) = g_k(x)$, which converges to $x_{\infty} := \delta(\tilde{x}_{\infty})$. Denoting $x_k^- = g_k(x^-)$ and $x_k^+ = g_k(x^+)$, $x_k^-$, $x_k^+$, and $x_k^+$ are three distinct points of $C^\beta(x_k)$ for any $k$. By compactness of $X$, we can assume up to extraction that $x_k^-$ and $x_k^+$ respectively converge to points $x_m^-$ and $x_m^+$ of $C^\beta(x_m)$, and the hypothesis (7.1) allows us to obtain the following crucial statement.

Fact 7.5. $x_{\infty} \neq x_m^-$ and $x_{\infty} \neq x_m^+$.

Proof. Let us assume for a contradiction that $x_m^- = x_{\infty}$. Considering a neighbourhood $U$ of $x_{\infty}$ such that $\delta|_U$ is injective, we can choose $\tilde{y}_{\infty} \in (\tilde{F}^\beta(\tilde{x}_{\infty}) \cap U) \setminus \{\tilde{x}_{\infty}\}$. There exists a sequence $\tilde{y}_k \in \tilde{F}^\beta(\tilde{x}_{\infty})$ converging to $\tilde{y}_{\infty}$, and possibly changing $\tilde{y}_k$, we can moreover assume that $\delta(\tilde{y}_k) = \{x_k^- \} \cup \{x_k^+\}$, implying that $\delta(\tilde{y}_{\infty}) = \{x_m^- \} \cup \{x_m^+\}$ by continuity. But as $x_{\infty} = x_{\infty}$, $\{x_m^- \} \cup \{x_m^+\} = \{x_m\}$, and therefore $\delta(\tilde{y}_{\infty}) = x_{\infty} = \delta(\tilde{x}_{\infty})$, implying $\tilde{y}_{\infty} = \tilde{x}_{\infty}$ by injectivity of $\delta|_U$, which contradicts our hypothesis on $\tilde{y}_{\infty}$. In the same way, we obtain $x_{\infty} \neq x_m^+$. □

The subgroup $SO(3)$ of $G$ acts transitively on $X$, and we can thus choose $\phi \in SO(3)$ and a sequence $(\phi_k)$ in $SO(3)$, satisfying $\phi(x) = o$ and $\phi_k(x_k) = o$ for any $k$ (we recall that $o = (\{e\}, \{e\})$). Since $\text{Stab}_{SO(3)}(C^\beta(o)) = SO(2)$ acts transitively on $C^\beta(o)$, we can moreover assume that $\phi(x^+) = o^+$ and $\phi_k(x_k^+) = o^+$, where $o^+ = (\{e\}, \{e, e\})$ in

Contact partially hyperbolic diffeomorphisms 2621
For any $k$, $\phi_k \circ g_k \circ \phi^{-1}$ is an element of $\text{Stab}_G(o) \cap \text{Stab}_G(o^+)$, that is, it is of the form
\[
\begin{bmatrix}
1 & 0 & x \\
0 & \lambda_k & y \\
0 & 0 & \mu_k
\end{bmatrix}.
\]
But
\[
\begin{bmatrix}
1 & 0 & * \\
0 & 1 & * \\
0 & 0 & *
\end{bmatrix}
\]
acts trivially in restriction to $C^\beta(o)$, and
\[
A_k := \begin{bmatrix} 1 & 0 & 0 \\ 0 & \lambda_k & 0 \\ 0 & 0 & 1 \end{bmatrix}
\]
therefore satisfies
\[
g_k|_{C^\beta(x)} = \phi_k^{-1} \circ A_k \circ \phi|_{C^\beta(x)}.
\]
The following commutative diagram summarizes the situation.
\[
\begin{array}{c}
C^\beta(o) \xrightarrow{\phi} C^\beta(x) \xleftarrow{A_k} \tilde{F}^\beta(\tilde{x}) \xrightarrow{\pi_M} \tilde{F}^\beta(\tilde{x}) \\
\downarrow A_k & \downarrow g_k & \downarrow \gamma_k f^n_k \\
C^\beta(o) \xleftarrow{\phi_k} C^\beta(x_k) \xrightarrow{\tilde{F}^\beta(\tilde{x}_k) \pi_M} \tilde{F}^\beta(\tilde{x}_k)
\end{array}
\]
(7.2)

The action of $A_k \in G$ on $C^\beta(o)$ is conjugated to the action of the projective transformations $\begin{bmatrix} 1 & 0 & \lambda_k \end{bmatrix} \in \text{PGL}_2(\mathbb{R})$ on $\mathbb{RP}^1$, that is, to the action of the homotheties of ratio $\lambda_k$ on $\mathbb{R} \cup \{\infty\}$. By this conjugation, $o$ corresponds to 0, $o^+$ corresponds to $\infty$, and $o^- := \phi(x^-) \in C^\beta(o) \setminus \{o, o^+\}$ corresponds to a non-zero point of $\mathbb{R}$. Fact 7.5 implies that $A_k(o^-) = \phi_k(x^-) \in C^\beta(o)$ stays bounded away from $o$ (since $\phi_k \in \text{SO}(3)$), and therefore that $\lambda_k$ is bounded away from 0.

On the other hand, endowing $\tilde{M}$ with the pullback of the Riemannian metric of $M$, diagram (7.2) implies $\lim_{k \to +\infty} \|D_x(\gamma_k f^n_k)|_{E^\beta(\tilde{x})}\|_{\tilde{M}} = 0$ (since $\pi_1(M)$ acts by isometries). Fixing any Riemannian metric on $X$, as $(\tilde{x}_k)$ is relatively compact we also have $\lim\|D_x g_k|_{E^\beta(\tilde{x})}\|X = 0$, and since $(\phi_k)$ and $(x_k)$ are relatively compact as well, we finally obtain $\lim\|D_o A_k|_{E^\beta(\tilde{x})}\|X = 0$.

This contradicts the fact that $\lambda_k$ is bounded away from 0, and this contradiction concludes the proof of the lemma.

Lemma 7.4 allows us to easily infer the path-lifting property in the $\alpha$- and $\beta$-directions.

**Corollary 7.6.**

1. For any $x \in \delta(\tilde{M})$, $C^\alpha(x) \cap \delta(\tilde{M}) = C^\alpha(x) \cap Y$ and $C^\beta(x) \cap \delta(\tilde{M}) = C^\beta(x) \cap Y$.
2. The paths in $\delta(\tilde{M})$ in the $\alpha$- and $\beta$-directions lift to $\tilde{M}$ from any point.

**Proof.** We only present proofs of the statements for the $\alpha$-direction, the case of the $\beta$-direction being formally the same.
For any \( \tilde{x} \in \tilde{M} \), denoting \( \delta(\tilde{x}) = x \), we know that \( \partial Y \cap C^\alpha(x) \) is equal to a single point \( \{x^*\} \) that satisfies \( C^\alpha(x) \setminus \{x^*\} = C^\alpha(x) \cap Y \). Furthermore, \( \delta(\tilde{F}^\alpha(\tilde{x})) = C^\alpha(x) \setminus \{x^*\} = C^\alpha(x) \cap Y \) according to Lemma 7.4. As \( C^\alpha(x) \cap \delta(M) \subset \bigcup_{\tilde{x} \in \delta^{-1}(x)} \delta(\tilde{F}^\alpha(\tilde{x})) = C^\alpha(x) \cap Y \), we finally obtain \( C^\alpha(x) \cap \delta(M) = C^\alpha(x) \cap Y \).

(2) Together with Lemma 7.4, we finally have \( \delta(\tilde{F}(\tilde{x})) = C^\alpha(x) \cap \delta(M) \), for any \( x \in \delta(M) \) and \( \tilde{x} \in \delta^{-1}(x) \). According to Remark 7.3, this proves that any path starting from \( x \) in the \( \alpha \)-direction lifts to \( M \) from \( \tilde{x} \).

The accessibility property of Lagrangian contact structures allows us to deduce the following.

**Corollary 7.7.** The developing map is surjective: \( \delta(M) = Y \).

**Proof.** Let \( x \) be a point of the non-empty subset \( \delta(M) \), and let \( y \) be any point in \( Y \). Restricting the Lagrangian contact structure \( \mathcal{L}_X = (E^\alpha, E^\beta) \) of \( X \) to the connected open subset \( Y \), [Sus73, Theorem 4.1] implies the existence of a finite number \( x = x_1, \ldots, x_n = y \) of points of \( Y \) such that for any \( i = 1, \ldots, n - 1 \), \( x_{i+1} \in C^\alpha(x_i) \cap Y \) or \( x_{i+1} \in C^\beta(x_i) \cap Y \). Applying the first statement of Corollary 7.6, we deduce by a direct finite recurrence that for any \( i, x_i \in \delta(M) \), so that \( y \in \delta(M) \).

We finally prove that the central paths also lift, by a specific method for each model.

**Lemma 7.8.** In the case of \( Y_t \), any central path starting at any point \( x \in Y_t \) lifts in \( \tilde{M} \) from any point \( \tilde{x} \in \delta^{-1}(x) \).

**Proof.** Let us recall that \( H_t = \left[ \begin{array}{cc} \text{GL}_2(\mathbb{R}) & 0 \\ 0 & 1 \end{array} \right] = \text{Aut}(Y_t, S_t) \) and \( o_t = ([1,0,1],[1,0,1],e_2) \in Y_t \). Since

\[
Z = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}
\]

is central in \( h_t \), the Killing field \( Z^\dagger \) of \( S_t \) associated with \( Z \) is \( H_t \)-invariant. As \( E^\alpha_t(o_t) = \mathbb{R}Z^\dagger(o_t) \) (see §4.2.2) and \( E^c \) is \( H_t \)-invariant as well, \( Z^\dagger \) actually generates the transverse distribution on \( Y_t \). At any point \( x \in Y_t \), we thus have \( \mathcal{F}_t^x(x) = \exp(\mathbb{R}Z) \cdot x \). Now, as the holonomy group \( \rho(\pi_1(M)) \) is contained in \( H_t \) according to Proposition 6.5, it leaves \( Z^\dagger \) invariant, and the pullback \( \tilde{X} := \delta^*Z^\dagger \) is thus preserved by the fundamental group \( \pi_1(M) \). This allows us to push \( \tilde{X} \) down on \( M \), to a Killing field \( X \) generating the central direction \( E^c \). As \( M \) is compact, \( X \) is a complete vector field, and as \( \pi_M: \tilde{M} \to M \) is a covering map, the pullback \( \pi_M X = \tilde{X} \) is also complete, implying that for any \( \tilde{x} \in \tilde{M} \), the central leaf at \( \tilde{x} \) is simply the integral curve of \( \tilde{X} = \delta^*Z^\dagger \) at \( \tilde{x} \). For any \( x \in Y_t \) and \( \tilde{x} \in \delta^{-1}(x) \) (which is non-empty because \( \delta(M) = Y_t \) according to Corollary 7.7) we thus have \( \delta(\tilde{F}^c(\tilde{x})) = \{ \delta(\phi_t^c(\tilde{x})) \mid t \in \mathbb{R} \} = \exp(\mathbb{R}Z) \cdot x = \mathcal{F}_t^x(x) \). This completes the proof of the lemma according to Remark 7.3.

**Lemma 7.9.** In the case of \( Y_a \), any central path starting at any point \( x \in Y_a \) lifts in \( \tilde{M} \) from any point \( \tilde{x} \in \delta^{-1}(x) \).
Proof. Let us first emphasize that the argument used in the previous lemma for the case of \( Y_t \) does not work here, because the centre of \( h_a \) is trivial.

We identify \( Y_a \) with \( \mathbb{R}^3 \) through \( (x, y, z) \in \mathbb{R}^3 \mapsto ([x, y, 1], ([x, y, 1], (z, 1, 0))] \in Y_a \), and we consider the following vector fields of \( Y_a \) in these global coordinates:

\[
X^\alpha(x, y, z) = e_3, \quad X^\beta(x, y, z) = (z, 1, 0), \quad X^c(x, y, z) = e_1.
\]

These vector fields are complete and generate the enhanced Lagrangian contact structure \( \mathcal{S}_a = (\mathcal{E}_a^\alpha, \mathcal{E}_a^\beta, \mathcal{E}_a^c) \) on \( Y_a \) (see §4.2.3). Since the paths tangent to the \( \alpha \)- and \( \beta \)-distributions entirely lift to \( \tilde{M} \) according to Corollary 7.6, we deduce that the pullbacks \( \tilde{X}^\alpha = \delta^* X^\alpha \) and \( \tilde{X}^\beta = \delta^* X^\beta \) are complete as well. We can furthermore realize the flow of the central vector field \( X^c \) by \( \alpha - \beta \) curves through the following equalities:

\[
\begin{align*}
\varphi_{X^\beta}^{-t} \circ \varphi_{X^\alpha}^{-t} \circ \varphi_{X^\beta}^{t} \circ \varphi_{X^\alpha}^{t}(x) &= x + t^2 e_1 = \varphi_{X^c}^{t^2}(x), \\
\varphi_{X^\beta}^{-t} \circ \varphi_{X^\alpha}^{-t} \circ \varphi_{X^\beta}^{t} \circ \varphi_{X^\alpha}^{t}(x) &= x - t^2 e_1 = \varphi_{X^c}^{-t^2}(x).
\end{align*}
\]

The same equalities are thus true for the pullbacks \( \tilde{X}^\alpha \), \( \tilde{X}^\beta \), and \( \tilde{X}^c = \delta^* X^c \), and since the flows of \( \tilde{X}^\alpha \) and \( \tilde{X}^\beta \) are defined for all times, these equalities show that \( \tilde{X}^c \) is also complete. The completeness of \( \tilde{X}^c \) allows us to lift any central path of \( Y_a \) from any point of \( \tilde{M} \), and concludes the proof of the lemma.

End of the proof of Proposition 7.1. According to Corollary 7.6 and Lemmas 7.8 and 7.9, the local diffeomorphism \( \delta \) satisfies the path-lifting property on \( Y \) in the \( \alpha, \beta \), and central directions, and is thus a covering map from \( \tilde{M} \) to \( Y \) according to Lemma 7.2.

8. Conclusion

8.1. End of the proof of Theorem B. The work that has been done so far tells us that for one of two models, \( (H, Y, S_Y) = (H_t, Y_t, S_t) \) or \( (H_a, Y_a, S_a) \), \( M \) is a \( (H, Y) \)-manifold whose developing map \( \delta : \tilde{M} \rightarrow Y \) is a covering map satisfying \( \delta^* S_Y = \tilde{S} \). With this information, we will complete the proof of Theorem B. We will use the link between the geometrical and algebraic point of views on the models \( (Y_t, S_t) \) and \( (Y_a, S_a) \), explained in §§4.1 and 4.2.

8.1.1. Case of \((Y_a, S_a)\). We first assume that \((M, S)\) is locally isomorphic to \((Y_a, S_a)\). Since \( Y_a \) is simply connected (because it is homeomorphic to Heis(3)), the covering map \( \delta : \tilde{M} \rightarrow Y_a \) is actually a diffeomorphism in this case. Since the developing map conjugates the action of \( \pi_1(M) \) on \( \tilde{M} \) to the action of the holonomy group \( \Gamma = \rho(\pi_1(M)) \subset H_a \) on \( Y_a \), we can assume without loss of generality that \( M \) is a compact quotient \( \Gamma \backslash Y_a \), with \( \Gamma \) a discrete subgroup of \( H_a \) acting freely, properly, and cocompactly. Since \( f \) is an automorphism of \((M, S)\), we moreover deduce from Proposition 6.4 that \( f \in \text{Nor}_{H_a}(\Gamma) \).

We saw in §4.2.3 that the identification between Heis(3) and \( Y_a \) given by the orbital map at \( o_a \) conjugates the action of \( H_a \) on \( Y_a \) and the action of the semi-direct product \( \text{Heis}(3) \rtimes \mathcal{A} \) of affine automorphisms of Heis(3), preserving its left-invariant structure. We can thus assume that \( M \) is a quotient \( \Gamma \backslash \text{Heis}(3) \), with \( \Gamma \) a discrete subgroup of \( \text{Heis}(3) \rtimes \mathcal{A} \) acting freely, properly, and cocompactly on Heis(3), and that \( f \in \text{Nor}_{\text{Heis}(3) \rtimes \mathcal{A}}(\Gamma) \).
Denoting
\[
[x, y, z] = \begin{pmatrix} 1 & x & z \\ 0 & 1 & y \\ 0 & 0 & 1 \end{pmatrix},
\]
the identification \([x, y, z] \in \text{Heis}(3) \mapsto (x, y, z) \in \mathbb{R}^3\) of \(\text{Heis}(3)\) with \(\mathbb{R}^3\) is equivariant for the following injective morphism from \(\text{Heis}(3) \rtimes A\) to the affine transformations of \(\mathbb{R}^3\):
\[
\Theta: ([x, y, z], \varphi_{\lambda, \mu}) \in \text{Heis}(3) \rtimes A \ni \begin{pmatrix} \lambda & 0 & 0 \\ 0 & \mu & 0 \\ 0 & \mu x & \lambda \mu \end{pmatrix} + \begin{pmatrix} x \\ y \\ z \end{pmatrix} \in \text{Aff}(\mathbb{R}^3).
\]

\(M\) is thus diffeomorphic to the quotient \(\Lambda \setminus \mathbb{R}^3\), where \(\Lambda := \Theta(\Gamma)\) is a discrete subgroup of affine transformations of \(\mathbb{R}^3\) contained in \(S := \Theta(\text{Heis}(3) \rtimes A)\), acting freely, properly, and cocompactly on \(\mathbb{R}^3\). Since \(S\) is solvable (because \(\text{Heis}(3) \rtimes A \simeq P_{\text{min}}\) is), the work of Fried and Goldman in [FG83] (more precisely, Theorem 1.4, Corollary 1.5, and §§3 and 4 of this paper) implies the existence of a so-called crystallographic hull \(C\) of \(\Lambda\). This group \(C\) is a closed subgroup of \(S\) containing \(\Lambda\), whose identity component \(C^0\) satisfies the following assumptions: \(\Lambda \cap C^0\) has finite index in \(\Lambda\) and is cocompact in \(C^0\); \(C^0\) acts simply transitively on \(\mathbb{R}^3\); and \(C^0\) is isomorphic to \(\text{Heis}(3)\), or \(\text{Sol}\). One can easily check that \(S\) does not contain any subgroup isomorphic to \(\mathbb{R}^3\), that the subgroups of \(S\) isomorphic to \(\text{Sol}\) do not act simply transitively on \(\mathbb{R}^3\), and that \(\Theta(\text{Heis}(3))\) is the only subgroup of \(S\) isomorphic to \(\text{Heis}(3)\). Finally, \(C^0\) is equal to \(\Theta(\text{Heis}(3))\), and therefore \(\Lambda \cap \Theta(\text{Heis}(3))\) has finite index in \(\Lambda\) and is cocompact in \(\Theta(\text{Heis}(3))\). As a consequence, \(\Gamma_0 := \Gamma \cap \text{Heis}(3)\) has finite index in \(\Gamma\) and is a cocompact lattice of \(\text{Heis}(3)\).

As morphism \(p: (g, \varphi) \in \text{Heis}(3) \rtimes A \ni \varphi \in A\) has a kernel equal to \(\text{Heis}(3)\), \(\Gamma / \Gamma_0\) is isomorphic to \(p(\Gamma) \subset A\). But \(A\) is isomorphic to \(\left(\mathbb{R}^+\right)^2\), and a finite subgroup of \(A\) is thus contained in the subgroup \(\{\varphi_{\pm 1, \pm 1}\}\) of cardinal four, implying that \(\Gamma_0\) is a subgroup of \(\Gamma\) of index at most four. As \((g, \varphi) \in \text{Nor}_{\text{Heis}(3) \rtimes A}(\Gamma)\), we have \(g \varphi(\Gamma_0)g^{-1} = \Gamma_0\), and the affine automorphism \(x \mapsto g \varphi(x)\) therefore induces a diffeomorphism \(\tilde{f}\) of \(\tilde{M} := \Gamma_0 \setminus \text{Heis}(3)\) through \(\tilde{f}(x \Gamma_0) = g \varphi(x) \Gamma_0\). The canonical projection \(\tilde{\pi} : \tilde{M} = \Gamma_0 \setminus \text{Heis}(3) \rightarrow M = \Gamma \setminus \text{Heis}(3)\) is a covering of finite order equal to the index of \(\Gamma_0\) in \(\Gamma\), and we have \(\tilde{\pi} \circ \tilde{f} = \tilde{f} \circ \pi\).

It only remains to show that \(\lambda < 1\) and \(\mu > 1\), or, on the contrary, to conclude that \(\tilde{f}\) is a partially hyperbolic affine automorphism of \(\text{Heis}(3)\). Let us assume by contradiction that \(\lambda < 1\) and \(\mu < 1\). Choosing a left-invariant volume form \(\nu\) on \(\text{Heis}(3)\), we have \((D_{\nu} \varphi)^* \nu = \lambda^2 \mu^2 \nu\), and \(\nu\) induces a volume form \(\tilde{\nu}\) on \(\tilde{M} = \Gamma_0 \setminus \text{Heis}(3)\) such that \(\tilde{f}^* \tilde{\nu} = \lambda^2 \mu^2 \tilde{\nu}\), because \(L_g\) preserves \(\nu\). As \(\tilde{f}\) is a diffeomorphism of the compact manifold \(\tilde{M}\), we must have \(\int_{\tilde{M}} \tilde{\nu} = \int_{\tilde{M}} \tilde{f}^* \tilde{\nu} = \lambda^2 \mu^2 \int_{\tilde{M}} \tilde{\nu}\), which is a contradiction because \(\int_{\tilde{M}} \tilde{\nu} \neq 0\) and \(\lambda^2 \mu^2 < 1\). The same argument shows that we cannot have \(\lambda > 1\) and \(\mu > 1\) either, which completes the proof of Theorem B in the case of the local model \((Y_a, S_a)\).

8.1.2. **Case of** \((Y_t, S_t)\). We now assume that \(S\) is locally isomorphic to \((Y_t, S_t)\). Identifying \(Y_t\) with \(\text{SL}_2(\mathbb{R})\) as explained in §4.2.2, we can lift the developing map \(\delta : M \rightarrow \text{SL}_2(\mathbb{R})\).
\( Y_t \) to a map \( \tilde{\delta} : M \to \widetilde{\text{SL}}_2(\mathbb{R}) \) through the universal cover morphism \( \pi_{\text{SL}_2(\mathbb{R})} : \widetilde{\text{SL}}_2(\mathbb{R}) \to \text{SL}_2(\mathbb{R}) \). As \( \delta \) is a covering map according to Proposition 7.1, \( \tilde{\delta} \) is a diffeomorphism because \( \widetilde{\text{SL}}_2(\mathbb{R}) \) is simply connected. As \( M \) is supposed to be orientable, \( \pi_1(M) \) preserves its orientation, implying that the holonomy group \( \text{SL}_2(\mathbb{R}) \) and the action of \( \text{SL}_2(\mathbb{R}) \) is contained in the subgroup \( H^+_t = \text{GL}_2^+(\mathbb{R}) \) of elements of positive determinant. We saw in §4.2.2 that the diffeomorphism \( \theta_{\alpha} \circ i : \text{SL}_2(\mathbb{R}) \to Y_t \) conjugates the action of \( \text{GL}_2^+(\mathbb{R}) \) on \( Y_t \) and the action of \( \text{SL}_2(\mathbb{R}) \times A \) on \( \text{SL}_2(\mathbb{R}) \). As \( \pi_{\text{SL}_2(\mathbb{R})} \) is equivariant for the projection \( \tilde{\text{SL}}_2(\mathbb{R}) \times \tilde{A} \to \text{SL}_2(\mathbb{R}) \times A \), we finally conclude that the diffeomorphism \( \tilde{\delta} : M \to \widetilde{\text{SL}}_2(\mathbb{R}) \) is equivariant for a morphism \( \tilde{\rho} : \pi_1(M) \to \widetilde{\text{SL}}_2(\mathbb{R}) \times A \). We can thus assume that \( M \) is a quotient \( \tilde{\Gamma} \backslash \widetilde{\text{SL}}_2(\mathbb{R}) \), with \( \tilde{\Gamma} \) a discrete subgroup of \( \widetilde{\text{SL}}_2(\mathbb{R}) \times \tilde{A} \) acting freely, properly, and cocompactly on \( \widetilde{\text{SL}}_2(\mathbb{R}) \). Possibly replacing \( f \) by \( f^2 \), we can assume that \( f \) preserves the orientation of \( M \), and Proposition 6.4 then implies that \( f = L_g \circ R_{t_f} \) with \((g, a') \in \text{Nor}_{\text{PSL}_2(\mathbb{R}) \times \tilde{A}} \tilde{\Gamma})\).

Denoting by \( r_1 : \widetilde{\text{SL}}_2(\mathbb{R}) \times \tilde{A} \to \widetilde{\text{SL}}_2(\mathbb{R}) \) the projection on the first factor, and with \( \tilde{\Gamma}_0 := r_1(\tilde{\Gamma}) \subset \widetilde{\text{SL}}_2(\mathbb{R}) \), we now prove the following result.

**Fact 8.1.** \( \tilde{\Gamma}_0 \) is a cocompact lattice of \( \widetilde{\text{SL}}_2(\mathbb{R}) \), and \( \tilde{\Gamma} \) is the graph-group \( \text{gr}((\tilde{\gamma}, \tilde{\Gamma}_0)) \) of a morphism \( \tilde{u} : \tilde{\Gamma} \to \tilde{\Gamma} \).

**Proof.** Choosing a generator \( z \) of the centre \( \tilde{Z} \) of \( \widetilde{\text{SL}}_2(\mathbb{R}) \), the finiteness of the level proved by Salein in [Sal99, Theorem 3.3.2.3] implies the existence of a non-zero integer \( k \in \mathbb{N}^* \) such that \( \tilde{\Gamma} \cap (\tilde{Z} \times \langle e \rangle) = \langle \langle z^k, e \rangle \rangle \). We will denote by \( \langle (g) \rangle \) the group generated by an element \( g \), and we introduce the group \( \text{PSL}_2(\mathbb{R})^k := \widetilde{\text{SL}}_2(\mathbb{R})/\langle \langle z^k \rangle \rangle \) and denote by \( p_k : \widetilde{\text{SL}}_2(\mathbb{R}) \to \text{PSL}_2(\mathbb{R})^k \) its universal cover. Then, denoting \( A_k = p_k(\tilde{A}) \) and \( \Gamma_k := (p_k \times p_k)(\tilde{\Gamma}) < \text{PSL}_2(\mathbb{R})^k \times A_k \), \( p_k \) induces a diffeomorphism \( \tilde{\rho}_k : \tilde{\Gamma} \backslash \widetilde{\text{SL}}_2(\mathbb{R}) \to \Gamma_k \backslash \text{PSL}_2(\mathbb{R})^k \) (because \( \ker p_k = \langle z^k \rangle \) and \( \langle z^k, e \rangle \in \tilde{\Gamma} \)), implying in particular that \( \Gamma_k \) acts freely, properly, and cocompactly on \( \text{PSL}_2(\mathbb{R})^k \).

We can now apply the work of Kulkarni and Raymond in [KR85] to \( \Gamma_k \). We denote by \( \pi : \widetilde{\text{SL}}_2(\mathbb{R}) \to \text{PSL}_2(\mathbb{R}) \) the universal cover morphism of \( \text{PSL}_2(\mathbb{R}) \) (of kernel \( \tilde{Z} \)), and by \( \pi_k : \text{PSL}_2(\mathbb{R})^k \to \text{PSL}_2(\mathbb{R}) \) the induced \( k \)-fold covering by \( \text{PSL}_2(\mathbb{R})^k \). Then, with \( \Gamma = (\pi \times \pi)(\tilde{\Gamma}) \) and \( \Gamma_0 = r_1(\Gamma) < \text{PSL}_2(\mathbb{R}) \) the projection on the first factor, the form [Tho14, Lemma 4.3.1] of Kulkarni and Raymond’s results proved by Tholozan implies that \( \Gamma_0 \) is a cocompact lattice of \( \text{PSL}_2(\mathbb{R}) \), and that \( \pi_k \circ r_1 | \Gamma_k \) is injective.

The first assertion ensures that \( \tilde{\Gamma}_0 \) is discrete in \( \widetilde{\text{SL}}_2(\mathbb{R}) \). The second implies that \( \Gamma = \text{gr}(u, \Gamma_0) \) is the graph-group of a morphism \( u : \Gamma_0 \to A = \pi(\tilde{A}) \). Since \( r_1 | \Gamma \) is also injective, this implies that \( \tilde{\Gamma} \) is the graph of a morphism \( \tilde{u} : \tilde{\Gamma}_0 \to \tilde{A} \), trivial on \( \tilde{\Gamma}_0 \cap \tilde{Z} \).

Since \( \tilde{Z} \cap \tilde{\Gamma}_0 = \langle z^k \rangle \) is finite, the projection \( \tilde{\Gamma}_0 \backslash \widetilde{\text{SL}}_2(\mathbb{R}) \to \Gamma_0 \backslash \text{PSL}_2(\mathbb{R}) \) has finite fibres, implying that \( \tilde{\Gamma} \) is a cocompact lattice as \( \Gamma_0 \backslash \text{PSL}_2(\mathbb{R}) \) is compact.

The projection \( \Gamma_0 = \pi(\tilde{\Gamma}_0) \) is a cocompact lattice of \( \text{PSL}_2(\mathbb{R}) \) according to the proof of Fact 8.1, and \( \Gamma_0 \backslash \text{Nor}_{\text{PSL}_2(\mathbb{R})}(\Gamma_0) \) is thus finite. Therefore, \( \tilde{\Gamma}_0 \backslash \text{Nor}_{\text{SL}_2(\mathbb{R})}(\tilde{\Gamma}_0) \) is finite as well, since the projection \( \tilde{\Gamma}_0 \backslash \text{Nor}_{\text{SL}_2(\mathbb{R})}(\tilde{\Gamma}_0) \to \Gamma_0 \backslash \text{Nor}_{\text{PSL}_2(\mathbb{R})}(\Gamma_0) \) has finite fibres \( (\tilde{Z} \cap \tilde{\Gamma}_0 = \langle z^k \rangle \) is finite according to the finiteness of the level).
Recall that $f = L_g \circ R_a$, where $(g, a') \in \text{Nor}_{\tilde{\text{SL}}_2(\mathbb{R})} \times A(\tilde{\Gamma})$. Therefore, $g \in \text{Nor}_{\tilde{\text{SL}}_2(\mathbb{R})}(\tilde{\Gamma}_0)$, and since $\tilde{\Gamma}_0 \setminus \text{Nor}_{\tilde{\text{SL}}_2(\mathbb{R})}(\tilde{\Gamma}_0)$ is finite, there exists $n \in \mathbb{N}^*$ such that $\gamma := g^n \in \tilde{\Gamma}_0$. Denoting $a := a^n a(\gamma)^{-1}$, we have $f^n = L_\gamma \circ R_{a^n} = R_a \circ (L_\gamma \circ R_{a(\gamma)})$. But $L_\gamma \circ R_{a(\gamma)}$ acts trivially on the quotient $\tilde{\Gamma} \setminus \text{SL}_2(\mathbb{R})$, and therefore $f = R_a$ is a non-zero time-map of the algebraic contact-Anosov flow $(R_a')$ on $\tilde{\Gamma} \setminus \text{SL}_2(\mathbb{R})$.

Let us underline that $(R_a')$ is indeed Anosov, because the work of Zeghib in [Zeg96, Proposition 4.2, p. 868] proves that $(R_a')$ is quasi-Anosov with the definition of Mañé, and Mañé proves in [Mañ77, Theorem A] that three-dimensional quasi-Anosov flows are Anosov.

This concludes the proof of Theorem B in the case where $\mathcal{S}$ is locally isomorphic to $(\mathcal{Y}_t, \mathcal{S}_t)$, and thus concludes its whole proof.

8.2. Proof of Theorem A. Theorem B directly implies Theorem A stated in the introduction thanks to an argument of Brin. More precisely, we obtain the following refined version of Theorem A, where no domination is required on the central direction, and where the two remaining directions can a priori be both contracted or both expanded.

**Corollary 8.2.** Let $M$ be a closed, connected, and orientable three-dimensional manifold, endowed with a smooth splitting $TM = E^\alpha \oplus E^\beta \oplus E^c$ such that $E^\alpha \oplus E^\beta$ is a contact distribution. Let $f$ be a diffeomorphism of $M$ that preserves this splitting, such that:

1. each of the distributions $E^\alpha$ and $E^\beta$ is either uniformly contracted or uniformly expanded by $f$; and
2. $\text{NW}(f) = M$.

Then the conclusions of Theorem A hold. In particular, $f$ is a partially hyperbolic diffeomorphism.

**Proof.** Since $E^\alpha \oplus E^\beta$ is contact and $M$ is connected, any two points of $M$ are linked by the concatenation of a finite number of paths, tangent either to $E^\alpha$ or to $E^\beta$ (this is, for example, a consequence of the work of Sussmann in [Sus73, Theorem 4.1]). In other words, the pair $(\mathcal{F}^\alpha, \mathcal{F}^\beta)$ of foliations associated with $(E^\alpha, E^\beta)$ is topologically transitive in the terminology of Brin in [Bri75]. Our hypothesis of uniform contraction or expansion of the distributions $E^\alpha$ and $E^\beta$ directly implies that $\mathcal{F}^\alpha$ and $\mathcal{F}^\beta$ are uniformly contracted or expanded in the terminology of [Bri75]. Since $\text{NW}(f) = M$ by hypothesis, [Bri75, Theorem 1.1] implies that $f$ is topologically transitive. In fact, although Brin states his result assuming that one of the distributions is contracted and the other one expanded, it is easy to see that his proof does in fact not use this assumption, and that the same proof works if both distributions are expanded or both are contracted.

We are now under the hypotheses of Theorem B, and its conclusions hold.

**Acknowledgement.** I would like to thank Charles Frances for proposing this subject to me, and for his valuable advice.
