Undifferentiated connective tissue disease presenting with vascular pattern of renal amyloidosis with carpel tunnel syndrome: A case report

Sham Sunder, Satyanand Sathi, Himanshu Mahapatra, Rajesh J, Anurag Gupta, Prabhu K

ABSTRACT

Introduction: The undifferentiated connective tissue disease (UCTD) is the clinical entity where the patients share the clinical symptoms of different connective tissue diseases but do not satisfy the classification criteria of the American College of Rheumatology for a particular connective tissue disease. Case Report: A 62-year-old female was presented with multiple joint pain, Raynaud’s phenomenon, alopecia, swelling of legs, hardening of skin of the fingers of hands, and carpel tunnel syndrome. Antinuclear antibody test was moderately positive. Antibodies to double-stranded DNA and for antiphospholipid (lupus anticoagulant and anticardiolipin), anticentromere, anti-Scl-70, Anti-Jo1, U1-RNP Anti-Ro/SSA, Anti-La/SSB, were negative. RA factor was also negative. Twenty-four hour urine showed nephrotic range proteinuria and renal biopsy showed vascular pattern of renal amyloidosis with changes of interstitial fibrosis. The patient was diagnosed as having UCTD with vascular pattern of renal amyloidosis with carpal tunnel syndrome with nephrotic syndrome (NSAIDS induced minimal change nephropathy) with chronic kidney disease stage 3. Conclusion: Undifferentiated connective tissue disease may lead to renal involvement in the form of vascular pattern of renal amyloidosis. Raynaud’s phenomenon and carpel tunnel syndrome both can, coexist and may herald inflammatory arthritis or an UCTD.

Keywords: Undifferentiated connective tissue disease, Vascular pattern of renal amyloidosis, Carpel tunnel syndrome

INTRODUCTION

The undifferentiated connective tissue disease (UCTD) is the clinical entity where the patients share the clinical symptoms of different connective tissue diseases but do not satisfy the classification criteria of the American College of Rheumatology for a particular connective tissue disease such as rheumatoid arthritis, systemic sclerosis, Sjögren’s syndrome, systemic lupus erythematosus, mix connective tissue disease, polymyositis or dermatomyositis [1, 2]. The diagnostic criteria for UCTD, requires a positive antinuclear antibody test and disease duration of at least three years [1]. UCTD may be associated with Raynaud’s phenomenon, arthralgia, and carpel tunnel syndrome [3]. Secondary amyloidosis is a result of chronic infection or inflammatory disease.
Nephrotic syndrome (minimal change nephropathy) may be the manifestation of NSAIDS abuse.

**CASE REPORT**

A 62-year-old female was presented with a three-year history of bluish discoloration of fingers of both hands on cold exposure, thickening of skin of all the fingers of hands, inability to clench the fist, multiple joint pains and progressive hair loss of scalp. She had a two-year history of tingling and numbness of both hands and an eight-month history of swelling of both lower limbs. Patient took on and off pain killers (NSAIDS) for joint pains for three years. Past history of diabetes, hypertension and family history of similar illness, were absent. On physical examination diffuse non-cicatrizing alopecia of scalp was present. Thickening and tightening of skin was present over the fingers of both hands (sclerodactyly). Motor system examination showed, bilateral wasting of thenar muscles of hands (Figure 1). Her laboratory profile is given in Table 1. Ultrasonography of abdomen showed right kidney 8.7×2.9 cm, left kidney 8.5×2.8 cm with maintained corticomedullary differentiation and increased cortical echogenicity. 2D-ECHO showed minimal pericardial effusion (ejection fraction 55%). Nerve conduction

| Table 1: Laboratory profile of patient |
|---------------------------------------|
| Hemoglobin                            | 8.5 g/dL |
| TLC                                   | 9300/mm³ |
| Platelet count                        | 2.8 lakhs/mm³ |
| ESR                                   | 90 mm |
| Serum hs-CRP                          | 6.8 mg/L |
| Blood urea                            | 69 mg/dL |
| Serum creatinine                      | 2.2 mg/dL (base line) |
|                                       | 1.7 mg/dL after 6 month follow up. |
| Serum albumin and globulin            | 2.8 mg/dL and 1.9 mg/dL |
| Serum C3                              | 113 mg/dL (83–177 mg/dL) |
| Serum C4                              | 22.8 mg/dL (16–47 mg/dL) |
| HBsAg/antiHCV/HIV 1,2                 | Non reactive |
| Serum protein electrophoresis         | 1.34 ((0.37-3.1) range in renal failure) |
| Serum free light chain assay (kappa/lambda) ratio | ((0.26-1.65) range without renal failure) |
| Anti nuclear antibody                 | Positive (moderately) |
| Anti-dsDNA                            | Negative |
| Lupus anticoagulant/anticardiolipin Ab | Negative |
| Anticentromere antibody               | Negative |
| Anti-Scl-70                           | Negative |
| Anti-Jo1                               | Negative |
| Anti-U1RNP                             | Negative |
| Anti-Ro/SSA, Anti-La/SSB              | Negative |
| RA factor                             | Negative |
| Urine routine and microscopy          | Protein 3+, sugar nil, pH 6.5, WBCs 4-6/hpf, RBCs 1-2/ hpf |
| 24-hour urine protein                 | 6.7 g/day (base line) |
|                                       | 2.6 g/day after 2 month follow-up |
|                                       | 226 mg/day after 6 month follow-up |
| Urine for bence-jones protein         | Negative |
velocity showed, motor-sensory neuropathy of bilateral median nerve and peroneal nerve. Renal biopsy, on light microscopy (Figure 2) showed non-proliferative morphology in viable glomeruli, global glomerular sclerosis in 7/18 (38.8%) glomeruli, secondary segmental tufts sclerosis in 2/18 (11.1%) of sampled glomeruli, focal chronic tubulointerstitial nephritis (moderate severity), mild arterial fibrointimal sclerosis and focal deposition of congophilic material in arterial/arteriolar walls (Figure 3). Immunofluorescence examination showed, kappa light chains smudgy mesangial entrapment, lambda light chains smudgy mesangial entrapment but all immunoglobulins and complements were negative. The patient was diagnosed as having UCTD with vascular pattern of renal amyloidosis with carpal tunnel syndrome with nephrotic syndrome with chronic kidney disease stage 3 (Modification of Diet in Renal Disease, eGFR: 32 mL/min/1.73 meter square body surface area). In the view of UCTD, the patient was started on low dose prednisolone 20 mg/day, hydroxychloroquine 200 mg twice a day, and low dose diuretic with calcium and vitamin D supplements. Prednisolone was tapered to 10 mg /day after completion of two months. Patient responded symptomatically and proteinuria decreased to 2.6 g/day from 6.7 g/day within two months. At six-month follow-up proteinuria was 226 mg/day and creatinine was 1.7 mg/dL.

**DISCUSSION**

The clinical features and laboratory profile of our case patient is suggestive of some systemic connective tissue disease but this patient does not fit in to the specific single connective tissue disease according to the classification criteria of the American College of Rheumatology. This type of clinical picture is presently classified as UCTD [1, 2]. Approximately, 20–40% of patients who have an undifferentiated diagnosis at onset, may develop a well defined particular CTD in long-term follow-up [4, 5]. This differentiation is generally completed after 5 to 10 years of the disease onset [4, 5]. Chronic (autoimmune) inflammatory disease is the most common cause (42.6% cases) of secondary renal amyloidosis or AA amyloidosis [6]. In renal amyloidosis, amyloid deposits may be found in different distribution patterns within the kidney compartments. The amyloid deposition occurs most commonly in glomerular compartment, approximately in 80% of the cases. The vascular pattern of renal amyloidosis may be found in 12.5–39% of cases [6]. In vascular pattern of renal amyloidosis, amyloid deposits are seen usually within arteries or arterioles [6]. Renal biopsy of case patient showed that viable glomeruli were unremarkable and did not show evidence of amyloid/
congophilic material deposition but occasional arteries/arterioles showed amorphous congophilic material which showed greenish birefringence in cong red stained sections, viewed under polarized light indicating amyloid deposition. In our patient, chronic (autoimmune) inflammatory disease that is UCTD is the possible cause of vascular pattern of renal amyloidosis. Another likely diagnostic possibility would include a podocytopathy (minimal change nephropathy) contributing to proteinuric illness, associated with pain killers (NSAIDS) for three years for rheumatological symptoms. Carpal tunnel syndrome (CTS) is an inflammatory disorder. It is a common entrapment neuropathy of median nerve. The mechanism of median nerve compression is presumably pressure in the carpal tunnels due to inflammatory changes. Like Raynaud’s phenomenon, CTS can occasionally herald inflammatory arthritis or a connective tissue disorder. Indeed, many patients with CTS may have an associated Raynaud’s phenomenon [7].

CONCLUSION

Undifferentiated connective tissue disease (UCTD) could be viewed as a distinct systemic autoimmune disease with a characteristic clinical and serological profile. It may lead to renal involvement in the form of vascular pattern of renal amyloidosis. Raynaud’s phenomenon and carpel tunnel syndrome both can, coexist and may herald inflammatory arthritis or an UCTD.
