Distribution of pericellular matrix molecules in the temporomandibular joint and their chondroprotective effects against inflammation

Wern Cui Chu 1,*, Shipin Zhang 1,*, Timothy J Sng 1,*, Yu Jie Ong 1, Wen-Li Tan 1, Vivien Y Ang 1, Casper B Foldager 2 and Wei Seong Toh 1,3

The objectives of this study were to (1) determine the distribution and synthesis of pericellular matrix (PCM) molecules (collagen VI, collagen IV and laminin) in rat temporomandibular joint (TMJ) and (2) investigate the effects of PCM molecules on chondrocytes against inflammation in osteoarthritis. Four zones (fibrous, proliferating, mature and hypertrophic) of condylar cartilage and three bands (anterior, intermediate and posterior) of disc were analysed by immunohistochemistry for the presence of PCM molecules in rat TMJs. Isolated chondrocytes were pre-treated with PCM molecules before being subjected to interleukin (IL)-1β treatment to stimulate inflammation. The responses of the chondrocytes were analysed using gene expression, nitric oxide release and matrix metalloproteinase (MMP)-13 production measures. Histomorphometric analyses revealed that the highest areal deposition of collagen VI (67.4%), collagen IV (45.7%) and laminin (52.4%) was in the proliferating zone of TMJ condylar cartilage. No significant difference in the distribution of PCM molecules was noted among the three bands of the TMJ disc. All three PCM molecules were expressed intracellularly by chondrocytes cultured in the monolayer. Among the PCM molecules, pre-treatment with collagen VI enhanced cellular proliferation, ameliorated IL-1β-induced MMP-3, MMP-9, MMP-13 and inducible nitric oxide synthase gene expression, and attenuated the downregulation of cartilage matrix genes, including collagen I, aggrecan and cartilage oligomeric matrix protein (COMP). Concurrently, collagen VI pretreatment inhibited nitric oxide and MMP-13 production. Our study demonstrates for the first time the distribution and role of PCM molecules, particularly collagen VI, in the protection of chondrocytes against inflammation.

INTRODUCTION

The pericellular matrix (PCM) was first described as a distinct feature of cartilage several decades ago. However, there is a recent emerging paradigm in the field to decipher the components of the PCM and their functional roles in chondrocyte biology and chondrogenesis. PCM is a specialized, thin layer of the extracellular matrix (ECM) that immediately surrounds the chondrocytes and serves as a transducer for both biochemical and biomechanical signals to the chondrocyte. The chondrocyte and PCM constitute the chondron. Therefore, the PCM plays an important role in maintaining the phenotype and integrity of the chondrocytes and is involved in (1) biochemical interactions with regulatory proteins (for example, growth factors); (2) the regulation of the mechanical environment of the chondrocyte; and (3) the maintenance of the microenvironment of the chondrocyte and control (prevention) of the chondrocyte interaction with the extracellular matrix molecules of the territorial matrix.

Biglycan, decorin, matrilins, collagen VI and XVIII/endostatin are key components of the PCM. Proteins that are normally associated with the basement membrane, including collagen IV, laminins, perlecan and nidogens, have been recently found to be prominently in the PCM surrounding the chondrocytes. Notably, perlecan, type IV collagen and laminins have been reported to be present in murine and human articular cartilage during development. Our prior study also demonstrated that the deposition of collagen IV and laminin in mesenchymal stem cell (MSC) pellet cultures followed an orderly spatialtemporal shift in pattern during chondrogenesis from a diffuse territorial and interterritorial distribution to a distinct pericellular localization, as observed in normal articular cartilage.

Although previous studies have demonstrated the presence of PCM molecules in various cartilage tissues, including knee joint articular cartilage, intervertebral disc and meniscus, no prior study has investigated the role and distribution of PCM molecules in

temporomandibular joint (TMJ) condylar cartilage and discs. The TMJ is unique compared with other synovial joints (articular cartilages) because it is composed primarily of fibrocartilage in both the condylar cartilage and disc. Therefore, the aim of our study was to investigate the presence and distribution of three PCM molecules, namely collagen VI, collagen IV and laminin, in the rat TMJ condylar cartilage and disc. We also examined the role of PCM molecules in the anabolic and catabolic responses of TMJ condylar chondrocytes and disc cells via the pretreatment of cells with PCM molecules before a pro-inflammatory interleukin (IL)-1β treatment to stimulate the inflammation that is present in osteoarthritis (OA). We hypothesized that collagen VI, collagen IV and laminin are synthesized by chondrocytes and disc cells, and these molecules are differentially distributed in TMJ condylar cartilage and disc. These proteins and distribution may protect condylar and disc chondrocytes against inflammation during OA.

MATERIALS AND METHODS

Animals

This study was conducted in compliance with the Institutional Animal Care and Use Committee at the National University of Singapore under protocol number R14-913. Twelve 8-week-old female Sprague-Dawley rats with a mean weight of (212.5 ± 17.1) g (range 180–230 g) were used in this study.

Histology, immunohistochemistry and histomorphometry

Three rats were euthanized, and the heads were resected. After the removal of overlying skin and connective tissue, the left and right TMJs of each animal (n = 6) were separated and fixed in 10% neutral-buffered formalin (Sigma, St. Louis, MO, USA) for 1 week and decalcified in 30% buffered formic acid. After the decalcification, the samples were dehydrated and embedded in paraffin. Ten serial sagittal sections were cut at 5 μm for each TMJ sample and randomly assigned to haematoxylin and eosin, and immunohistochemical staining. Immunohistochemistry to detect collagen VI (ab6588; 0.1 μg·mL⁻¹; Abcam, Cambridge, MA, USA), collagen IV (ab6586; 0.5 mg·mL⁻¹; Abcam, Cambridge, MA, USA) and laminin (ab11575; 0.5 μg·mL⁻¹; Abcam, Cambridge, MA, USA) were performed using a biotin-streptavidin Lab Vision UltraVision detection system (Thermo Fisher Scientific, Waltham, MA, USA), as previously described. An antibody isotype control (X0903; Dako, Glostrup, Denmark) was included to ensure the specificity of the immunohistochemical staining.

For the histomorphometric analysis, 40–60 images were taken for each sample at a magnification of ×20 under an inverted microscope (Olympus IX70; Olympus, Tokyo, Japan). All the images taken for each sample were assembled to form an image of the entire TMJ, and all the samples were included in the analysis. The anterior, intermediate and posterior bands of the disc, excluding the vascularized ends, were identified for the analysis. The fibrous, proliferative, mature and hypertrophy zones of the condylar cartilage were demarcated for the analysis (Figure 1). The percentage of the positively stained areas was analysed using ImageJ software (National Institutes of Health, Bethesda, MD, USA), as previously described.

Cell culture

Condylar chondrocytes and disc cells were harvested from nine rats. The tissues were washed 3 times with phosphate-buffered saline (PBS) and digested with 0.2% collagenase I and II (Worthington, Lakewood, NJ, USA) overnight at 37 °C. The cells were passed through a 40-μm cell strainer (Corning, Corning, NY, USA) to obtain single cells before seeding at a density of 20 000 cells per cm². The culture was maintained in Dulbecco’s modified Eagle’s Medium-Ham’s F12 (DMEM-F12, Biowest, Nuaille, France) supplemented with 10% foetal bovine serum (FBS, BioWest, Nuaille, France), 25 μg·mL⁻¹ ascorbic acid 2-phosphate (AA2P, Sigma, St Louis, MO, USA), and 1% penicillin-streptomycin (PS; Life Technologies, Carlsbad, CA, USA) under a humidified atmosphere of 5% CO₂ at 37 °C. The medium was changed every alternate day. Chondrocytes were dissociated at confluence using TrypLe (Life Technologies, Carlsbad, CA, USA) and further sub-cultured to passage 2 (P2) to yield a sufficient number of cells for further experiments.

Immunocytochemistry of cell culture

Condylar and disc chondrocytes were cultured in 24-well plates at a density of 20 000 cells per cm² overnight. Immunofluorescence staining of monolayer culture samples was performed as previously described. In brief, the monolayer culture samples were fixed in 4% paraformaldehyde (Sigma, St. Louis, MO, USA), permeabized with 0.3% Triton X-100 (Sigma, St. Louis, MO, USA) and incubated overnight at 4 °C with primary antibodies for collagen VI, collagen IV and laminin. After the incubation, the cells were washed twice with 0.3% Triton X-100 in PBS and incubated with an Alexa Fluor 594 goat anti-rabbit secondary antibody (A11012; Life Technologies, Carlsbad, CA, USA). Nuclear staining was performed using 4',6-diamidino-2-phenylindole (DAPI; Life Technologies, Carlsbad, CA, USA) before

Results

Distribution of PCM molecules in the TMJ
TMJ sections from all three animals (six TMJs) displayed immunoreactivity for PCM molecules, including collagen VI, collagen IV and laminin. Positive staining of PCM molecules was observed in the subchondral bone underlying the condylar cartilage and the lining of blood vessels at the vascularized ends of the TMJ disc. However, these regions were excluded from the analysis since this study intended to investigate the pericellular localization of these molecules in the cartilaginous tissues of TMJ, namely the condylar cartilage and disc. All six TMJs examined from the three animals showed positive staining for the PCM molecules (collagen VI, collagen IV and laminin) in both the condylar cartilage and disc. However, no distinguishable difference in the staining was noted between the left and right TMJs.

The TMJ condylar cartilage displayed pericellular localization of the PCM molecules surrounding the chondrocytes, albeit at varying amounts in the different zones. The total area of positive staining varied among the three PCM molecules, with collagen VI showing the highest areal deposition (42.68% ± 2.88%) compared with collagen IV (18.32% ± 1.64%) and laminin (23.93% ± 2.45%; P < 0.001). Histo-morphometric analyses in different zones of the condylar cartilage revealed the highest areal deposition of collagen VI (67.39% ± 1.97%), collagen IV (45.69% ± 5.61%) and laminin (52.38% ± 7.81%) in the proliferating zone of TMJ condylar cartilage (Figure 2a and 2b, Table 1). In contrast, the hypertrophic zone of TMJ condylar cartilage showed the lowest level of collagen VI (22.8% ± 2.67%), collagen IV (1.82% ± 0.25%) and laminin (10.5% ± 1.26%). No chromogen was detected in any of the isotype control TMJ sections (data not shown).

Pericellular localization of the PCM molecules surrounding individual chondrocytes was found throughout the length of the disc in the TMJ disc samples. The total area of positive staining varied among the three PCM molecules. The highest areal deposition of collagen VI (27.77% ± 1.03%) compared with collagen IV (24.91% ± 1.58%) and laminin (12.95% ± 2.21%) was also found in the TMJ disc. However, there was no significant difference in the distribution of PCM molecules (collagen VI, collagen IV and laminin) among the three bands of the TMJ disc (Figure 2a and 2b, Table 1).

Presence of PCM molecules in monolayer cultures of TMJ condylar and disc chondrocytes
Condylar chondrocytes appeared flattened and fibroblastic in the monolayer cultures, and the disc cells appeared spindle-shaped and slightly elongated (Figure 3a). All three PCM molecules, collagen VI, collagen IV and laminin, were observed in the monolayer cultures of
cells derived independently from three rats (Figure 3b). A similar pattern of intracellular staining was observed for all three PCM molecules in both condylar and disc cells (Figure 3b). Some deposition of these molecules was also observed in the culture environment surrounding the cells.

Effects of PCM molecules on the proliferation of TMJ condylar and disc chondrocytes

The TMJ condylar and disc chondrocytes were individually pooled from six animals for culture to P2 for the cellular experiments. We investigated the proliferative effect of the PCM molecules on condylar and disc chondrocytes over 48 h. Notably, soluble collagen VI significantly increased cell proliferation in a dose-dependent manner in both condylar and disc chondrocytes (Figure 4a and 4b). A significant enhancement in cell proliferation by collagen VI was observed as early as 24 h. By the end of the 48 h treatment, a significant enhancement (~420%) in proliferation was observed in cells treated with 2 μg·mL⁻¹ collagen VI compared with the untreated controls (P<0.001). A moderate increase (~10%) in the cell proliferation of condylar and disc chondrocytes was observed with the collagen IV treatment. Minimal changes in cell proliferation were observed with the laminin treatment (Figure 4a and 4b).

To test the proliferative effects of PCM molecules against inflammation, both condylar and disc chondrocytes were pre-treated with PCM molecules before the treatment with IL-1β to stimulate inflammation. Among the three PCM molecules, pre-treatment with collagen VI consistently enhanced the cellular viability and proliferation of condylar chondrocytes (~10%) and disc chondrocytes (~20%) compared with untreated and IL-1β-treated cells (P<0.001; Figure 4c).
In contrast, pretreatment with collagen IV and laminin did not produce notable proliferative effects in the presence of inflammation.

Pre-treatment effects of PCM molecules on IL-1β-induced gene expression
To test the protective effects of PCM molecules against inflammation, both condylar and disc chondrocytes were pre-treated with the PCM molecules before the treatment with IL-1β to stimulate inflammation. Both condylar and disc chondrocytes showed similar patterns in gene expression in response to the catabolic effects of the IL-1β treatment (Figure 5a and 5b). Notably, the IL-1β treatment significantly upregulated the expression of genes associated with matrix degradation, including MMP-3, MMP-9, MMP-13 and iNOS, for both the condylar and disc chondrocytes compared with their untreated counterparts ($P<0.001$; Figure 5a and 5b). Among the three PCM molecules, pre-treatment with collagen VI consistently reduced the IL-1β-induced upregulation of MMP-3, MMP-9, MMP-13 and iNOS in both the condylar and disc chondrocytes compared with IL-1β-
Figure 4 Effect of PCM molecules on condylar and disc chondrocyte proliferation. (a) Condylar chondrocytes and (b) disc chondrocytes treated with various concentrations of collagen VI, collagen IV or laminin were assessed for proliferation using the MTS assay at 24 and 48 h. (c) Condylar chondrocytes (left panel) and disc chondrocytes (right panel) pre-treated with collagen VI, collagen IV and laminin were subjected to IL-1β-induced inflammation for 24 h. Cell viability was assessed using the MTS assay. Mean ± s.e.m.; n=4. #P<0.05; ##P<0.01; ###P<0.001, compared with untreated control. ***P<0.001, compared with IL-1β-treated group. h, hours; IL-1β, interleukin-1β; PCM, pericellular matrix.
treated cells ($P<0.05$; Figure 5a and 5b). In contrast, pretreatment with collagen IV and laminin did not reduce the expression of MMP-3, MMP-9, and iNOS in either cell type treated with IL-1β. However, laminin pretreatment significantly reduced MMP-13 expression in disc chondrocytes ($P<0.05$) but not in condylar chondrocytes ($P=0.622$; Figure 5a and 5b).

The IL-1β treatment consistently downregulated the expression of cartilage matrix genes, including ACAN, COL-1, and COMP, in condylar and disc chondrocytes (Figure 6a and 6b). In condylar chondrocytes, IL-1β significantly downregulated ACAN, but no significant differences in the levels of COL-1 and COMP were observed compared with the untreated controls. In the disc cells, there were at least twofold reductions in the expression of ACAN ($P<0.01$), COL-1 ($P<0.001$) and COMP ($P<0.001$) with the IL-1β treatment. Among the PCM molecules, pre-treatment with collagen VI generally reduced the adverse effect of the IL-1β-induced downregulation of ACAN, COL-1 and COMP in both condylar and disc chondrocytes. In the condylar chondrocytes, pre-treatment with collagen VI significantly ameliorated the downregulation of ACAN, COL-1 and COMP compared with their IL-1β-treated counterparts ($P<0.05$; Figure 6a and 6b). In contrast, collagen IV and laminin...
pretreatment did not reduce the IL-1β-induced downregulation of ACAN, COL-1 and COMP expression in either cell type (Figure 6a and 6b).

Pre-treatment effects of PCM molecules on IL-1β-induced NO and MMP-13 production
We further investigated the effect of PCM molecules on NO and MMP-13 production by primary condylar and disc chondrocytes. The IL-1β treatment significantly increased NO production in both condylar and disc chondrocytes compared with the untreated controls ($P<0.001$; Figure 7a and 7b). Among the three PCM molecules, pre-treatment with collagen VI consistently reduced the IL-1β-induced upregulation of NO production in both condylar and disc chondrocytes compared with IL-1β-treated cells ($P<0.01$; Figure 7a and 7b). In contrast, collagen IV pretreatment significantly reduced NO production in condylar chondrocytes ($P<0.05$), but not disc chondrocytes ($P=0.482$), compared with their IL-1β-treated counterparts. However, there was no effect of laminin on IL-1β-induced NO production in either cell type.

Similarly, IL-1β treatment significantly increased MMP-13 production in both condylar and disc chondrocytes compared with the untreated controls ($P<0.05$; Figure 7c and 7d). Among the three PCM molecules, pre-treatment with collagen VI consistently reduced the IL-1β-induced upregulation of MMP-13 production in both condylar and disc chondrocytes compared with IL-1β-treated cells ($P<0.01$; Figure 7c and 7d). However, collagen IV and laminin demonstrated no effect on IL-1β-induced MMP-13 production in either cell type.

DISCUSSION
This study describes the spatial distribution of PCM molecules, including collagen VI, collagen IV and laminin, in normal TMJ condylar cartilage and disc tissues and demonstrates for first time the differential protective roles of these molecules against the IL-1β-induced inflammation that is present in OA. Several molecules have been identified to be present in the PCM surrounding individual chondrocytic cells in different cartilage tissues, including knee joint cartilage, meniscus and intervertebral discs. Among these PCM molecules, collagen VI and, more recently, the basement membrane molecules (collagen IV and laminin) have been widely postulated to have a role in the maintenance of cartilage homeostasis and mechanical integrity.

Our results demonstrated the presence and distribution of collagen VI, collagen IV and laminin in healthy TMJ condylar and disc tissues

![Figure 6 Effects of PCM molecules on matrix synthetic gene expression.](image-url)
in rats. These molecules are uniquely localized in the PCM and
surround individual chondrocytes. The question of the origin of these
PCM molecules in the TMJ is central to these findings. Of interest,
chondrocytes are the major source of PCM molecules.

In the TMJ condylar cartilage, it has been well-established that
collagen I is predominantly detected in the fibrous zone while collagen
II is primarily localized in mature and hypertrophic zones. The
proliferative zone is primarily a cellular region with relatively few
collagen fibres. Notably, all three PCM molecules were most
abundant in the proliferative zone of the condylar cartilage, which
consists of mesenchymal precursor cells involved in matrix synthesis
and organization in response to the external environment.

In contrast, all three PCM molecules were evenly distributed across
the three bands of the TMJ disc. The highest zonal deposition of all
three PCM molecules in the proliferative zone of TMJ condylar
cartilage may be related to the role of these molecules in the cellular
proliferation of TMJ chondrocytes. Notably, collagen VI exerted
the most potent proliferative effect on both condylar and disc chondrocytes,
even in the presence of IL-1β-induced inflammation. This result
may be related to the relatively higher amounts of collagen VI than
collagen IV and laminin in the condylar cartilage and disc tissues. This
finding is consistent with a recent study that demonstrated enhanced
proliferation of normal and OA human chondrocytes after treatment
with soluble collagen VI.

Previous studies reported a perturbation and/or changes in PCM as
a result of degenerative changes during OA. It is well-established that
IL-1β levels in the synovial fluid of TMJ correlate with OA
changes. IL-1β is a major pro-inflammatory cytokine in OA that
exhibits destructive effects that encompass increased cartilage degra-
dation and suppression of cartilage matrix synthesis. This study
demonstrated that collagen VI pretreatment ameliorated IL-1β-
induced matrix degradation and reduced the catabolic loss in the
chondrocytic phenotype of condylar and disc chondrocytes. This
finding is somewhat consistent with a recent study that collagen VI
pretreatment effectively prevented knee articular chondrocytes from
monoidoacetate-induced cell apoptosis, which suggests protective
effects of collagen VI in overall chondrocyte survival and inflammatory
response. This role of collagen VI is further supported by transgenic
knockout mouse studies, which demonstrated that collagen VI
knockout mice showed accelerated osteoarthritic changes in the hip
accompanied with decreased bone mass density because of a collagen
VI deficiency.

Although our results demonstrated little to no effect of collagen IV
and laminin on both condylar and disc chondrocytes against IL-1β-
induced inflammation, these basement membrane molecules (collagen
IV and laminin) are likely involved in other major cellular processes,
such as chondrogenic differentiation. Schminke et al. recently
reported the role of laminin and nidogen-2 in the chondrogenic
differentiation of chondrogenic progenitor cells and chondrocytes in
three-dimensional (3-D) alginate bead cultures.

Future studies should examine the changes in expression of these
PCM molecules in relevant TMJ-OA animal models to better establish
the role of these molecules, particularly collagen VI, in cartilage
metabolism during inflammation that is present in TMJ-OA. It
would also be of interest to investigate the effects of endogenous
and soluble exogenous PCM molecules on the survival, proliferation
and differentiation of chondrocytes and mesenchymal progenitor cells.

Collectively, this study shows the presence and distribution of PCM
molecules, including collagen VI, collagen IV and laminin, in TMJ
condylar cartilage and discs. Among the PCM molecules, collagen VI
demonstrates proliferative and protective effects on TMJ chondrocytes
against IL-1β-induced inflammation. These findings of PCM
molecules, particularly collagen VI, may aid in the discovery of early
biomarkers for TMJ-OA and the elucidation of new measures and
