DOMAIN VARIATIONS AND MOVING BOUNDARY PROBLEMS

PATRICK GUIDOTTI

Abstract. In the past few decades maximal regularity theory has successfully been applied to moving boundary problems. The basic idea is to reduce the system with varying domains to one in a fixed domain. This is done by a transformation, the so-called Hanzawa transformation, and yields a typically nonlocal and nonlinear coupled system of (evolution) equations. Well-posedness results can then often be established as soon as it is proved that the relevant linearization is the generator of an analytic semigroup or admits maximal regularity. To implement this program, it is necessary to somehow parametrize to space of boundaries/domains (typically the space of compact hypersurfaces $\Gamma$ in $\mathbb{R}^n$, in the Euclidean setting). This has traditionally been achieved by means of the already mentioned Hanzawa transformation. The approach, while successful, requires the introduction of a smooth manifold $\Gamma_\infty$ close to the manifold $\Gamma_0$ in which one cares to linearize. This prevents one to use coordinates in which $\Gamma_0$ lies at their “center”. As a result formulæ tend to contain terms that would otherwise not be present were one able to linearize in a neighborhood emanating from $\Gamma_0$ instead of from $\Gamma_\infty$. In this paper it is made use of flows (curves of diffeomorphisms) to obtain a general form of the relevant linearization in combination with an alternative coordinatization of the manifold of hypersurfaces, which circumvents the need for the introduction of a “phantom” reference manifold $\Gamma_\infty$ by, in its place, making use of a “phantom geometry” on $\Gamma_0$. The upshot is a clear insight into the structure of the linearization, simplified calculations, and simpler formulæ for the resulting linear operators, which are useful in applications.

1. Introduction

Moving boundary problems are ubiquitous and numerous in applications. Latter include, but are by no means limited to, fluid dynamics with, e.g., the classical Stefan problem, and biology with, e.g models of tumor growth.

In abstract terms such problems consist of a system of (initial) boundary value problems for unknown physical quantities (read concentrations, velocity fields, temperature, ...) and for at least one unknown (evolving) domain in which the boundary value problems are set. Even when the equations for the unknown physical quantities appear linear, the system is not, due to the coupling with the geometry. Indeed, two solutions living on two distinct domains can not be added to obtain a new solution on a new domain.

A versatile general purpose approach to (fully) nonlinear evolution equations of parabolic type is given by optimal (also maximal) regularity theory, see e.g. [8, 2, 1]. In a nutshell, the approach consists in linearizing a nonlinear equation/system in a point in the space of unknowns, prove that the linearization is an isomorphism (between carefully chosen function spaces), and eventually solving the equations by a perturbation argument.

In the context of free and moving boundary problems, linearization in the unknown necessarily includes taking domain variations (recall that the domain is itself an unknown of the problem). This amounts to measuring the infinitesimal dependence of functions, differential operators, pseudodifferential operators, and geometric quantities on the domains on which they are defined.

To be more specific consider a domain $\Omega_0$ in $\mathbb{R}^n$, $n \in \mathbb{N}$, defined by its boundary $\Gamma_0$ as the bounded region inside of it. It is supposed that $\Gamma_0$ be a compact hypersurface of limited regularity, say $C^2$, for now. For technical reasons that will become more explicit shortly, the parametrization problem has traditionally been solved by introducing coordinates in a neighborhood of $\Gamma_0$ (it is
clearly enough to vary the boundary as a means to vary the domain) based on a smooth (C^∞ or analytic) manifold Γ_∞ arbitrarily close to Γ_0 (in the C^2 sense). The basic idea consists in parametrizing the surface Γ_0 over Γ_∞ as a graph in “normal direction”, that is, by a function ρ_0 : Γ_0 → R via
\[ Γ_0 = \{ y + ρ_0(y)ν_∞(y) \mid y ∈ Γ_∞ \}, \]
where ν_∞ is the (smooth) outward unit normal to Γ_∞. In this way, the unknown domain can be described (locally in time, but this is enough) as an unknown function and the geometry (read ν_∞) does not impose any limitations since it is taken to be smooth. Notice that it would be impossible to choose Γ_0 as a reference manifold since it would require one to use its unit outward normal field ν_0, which enjoys one less degree of regularity as compared to the manifold itself. As shall become evident later, this loss of regularity cannot be afforded if one is to take the optimal regularity approach briefly sketched above. This is the core idea of the transformation, which was first employed for the Stefan problem [5], and that has become known as the Hanzawa transformation. This approach has been used repeatedly and was nicely expounded in [10].

It is the purpose of this paper to overcome the “regularity issue” in an alternative way that does not require the use of a smooth reference manifold, but rather uses the surface Γ_0 as the center of the coordinate patch, in which, after all, the linearization is needed. The idea can be simply stated: instead of using a smooth “phantom manifold” Γ_∞, introduce a regularized normal field ν_0^δ on Γ_0 and use it to parametrize a neighborhood of Γ_0 in the space of surfaces. This can be thought of as using a “phantom geometry” on Γ_0. Notice that in the smooth case, the two approaches coincide, since Γ_0 with its natural geometry can always be chosen as reference manifold. In this respect, the two approaches coincide in the smooth context. An additional goal of this paper is to offer a more geometrical approach to the issue of linearization. It uses flows and, more in general, curves of diffeomorphisms to conveniently identify it. This results in simpler and more transparent calculations which can be performed before the parametrization described above for the unknown surface is introduced, at the very end, in order to obtain a system of PDEs for unknown functions only.

An added advantage of the approach is the simplified form taken by the linearization which significantly shortens the analysis required to prove that it is a generator of an analytic semigroup, enjoys maximal regularity, or to obtain spectral information for stability analysis. Prototypical examples are discussed at the end of the paper.

2. Preliminaries

Basic facts from differential geometry and manifold theory will be used freely in the sequel. It is referred to standard references such as [6, 7, 11] for the required background. For α ∈ (0, 1) and k ∈ N, denote by \( M^{k+\alpha} \) the space of embedded hypersurfaces of \( \mathbb{R}^n \) given by
\[ M^{k+\alpha} = \{ Γ ⊂ \mathbb{R}^n \mid Γ \text{ compact, orientable hypersurface of class buc}^{k+\alpha} \}, \]
for k ∈ N and where the regularity space buc^{k+α} is the so-called little Hölder space. For an open subset \( O ⊂ \mathbb{R}^n \), the latter is defined as the closure of the regular space of bounded and uniformly Hölder continuous functions given by
\[ \text{BUC}^{k+\beta}(O) = \{ f : O → \mathbb{R} \mid f ∈ \text{BUC}^k(O) \text{ and } \partial^γ f ∈ \text{BUC}^\beta(O) \text{ for } |γ| = k \}, \]
with \( \beta > \alpha \), in the topology determined by the norm \( \| \cdot \|_{2+\alpha,∞} \) defined through
\[ \| f \|_{k+\alpha,∞} = \max_{|γ|≤k} \| \partial^γ f \|_{∞} + \max_{|γ|=k} [\partial^γ f]_{α}, \]
where
\[ |g|_\alpha = \sup_{x \neq y} \frac{|g(x) - g(y)|}{|x - y|^{\alpha}}, \quad g \in C(O). \]

If \( O \) is replaced by a compact manifold \( M \in \text{buc}^{k+\alpha} \), then the spaces \( \text{buc}^{l+\beta}(M) \), for \( l \leq k \) and \( \beta \in (0,1) \) with \( \beta \leq \alpha \) if \( l = k \), are defined in the standard way by resorting to localizations combined with a smooth partition of unity.

**Remark 2.1.** The choice of little H"older spaces is motivated by the ease provided by the use of a family of function spaces with dense embeddings in one another in the context of maximal regularity for generators of analytic semigroups. The space \( \text{buc}^\alpha(M) \) consists of those \( \text{BUC}^\alpha(M) \) functions \( g \) satisfying
\[
\lim_{\delta \to 0} \sup_{y \neq z \in M(x,\delta)} \frac{|g(y) - g(z)|}{d_M(y,z)^\alpha} = 0.
\]

For all considerations preceding the final examples, they can be replaced by the more standard classes of H"older regularity \( \text{BUC}^{k+\alpha} \), of which they are closed subspaces.

While this choice of spaces is not essential until maximal regularity results are used and, even then not unique, it is made for consistency with the final part of the paper and for simplicity of presentation. It is referred to [3] and the references cited therein for alternative functional settings in which maximal regularity holds. As the preferred spaces are a matter of taste and not of necessity in most applications, the choice made here is not restrictive but allows for a more concise presentation.

The Haussdorff distance on compact subsets defined by
\[
d_c(K,\overline{K}) = \max \left\{ \max_{x \in K} d(x,\overline{K}), \max_{x \in \overline{K}} d(x,K) \right\}
\]
can be used to define a distance \( d_{C^1} \) between \( \Gamma,\overline{\Gamma} \in \mathcal{M}^{1+\alpha} \) in the following manner
\[
d_{C^1}(\Gamma,\overline{\Gamma}) = d_c((\mathcal{N}\Gamma),\mathcal{N}\overline{\Gamma}) \tag{2.2}
\]
where
\[
\mathcal{N}\Gamma = \{ (y,\nu_\Gamma(y)) \mid y \in \Gamma \} \subset \mathbb{R}^{2n},
\]
where \( \nu_\Gamma(y) \) denotes the unit, outward pointing normal to \( \Gamma \) at \( y \). Proximity in \( d_{C^1} \) therefore implies not only that the hypersurfaces are close to each other but that also their tangent spaces cross everywhere at a uniformly small angle. This is used to exclude “rough” (oscillatory) approximations. Given \( \Gamma_0 \in \mathcal{M}^{2+\alpha} \), a little room is needed in which to operate. It is provided by the following lemma.

**Lemma 2.2** (Existence of a tubular neighborhood). *Given \( \Gamma_0 \in \mathcal{M}^{2+\alpha} \), there is \( r_0 > 0 \) such that
\[
T_{r_0}(\Gamma_0) := \{ x \in \mathbb{R}^n \mid d(x,\Gamma_0) < r_0 \}
\]
is an open neighborhood of \( \Gamma_0 \) diffeomorphic to \( \Gamma_0 \times (-r_0,r_0) \).*

Notice that \( d(\cdot,\Gamma_0) \) will always denote the signed distance to \( \Gamma_0 \) with the understanding that it is negative in the interior of the domain bounded by \( \Gamma_0 \).

**Proof.** While the proof is well-known, it is given anyway as a way to introduce some notation which will be useful again later.

By assumption \( \Gamma_0 \) has bounded principal curvatures. Fix a point \( y \in \Gamma_0 \) and choose coordinates \( s = (s^1,\ldots,s^{n-1}) \) such that \( \tau^0_j = \frac{\partial}{\partial s^j}, \quad j = 1,\ldots,n-1 \), is an orthonormal basis of \( T_y\Gamma_0 \) consisting of principal directions, i.e. satisfying
\[
d_{s^j} \nu_0 = \left. \frac{d}{ds^j} \right|_{s=0} \nu_0 = \lambda_j^0 \tau^0_j \quad \text{for} \quad j = 1,\ldots,n-1.
\]
where \( \nu_0 = \nu_{r_0} \) and the dependence on \( y \) or \( s \) is omitted, and \( \lambda_j^0 \) are the principal curvatures of \( \Gamma_0 \) at \( y \). It is assumed that \( \tau_1^0, \ldots, \tau_{n-1}^0, \nu_0 \) is a positively oriented orthonormal basis of \( T_y \mathbb{R}^n \). Define the map

\[
\Phi : \Gamma_0 \times (-r_0, r_0) \to \mathbb{R}^n, \quad (y, r) \mapsto y + r\nu_0(y),
\]

and notice that \( \Phi \in \text{buc}^{1+\alpha} \). It follows from the choice of coordinates that

\[
\frac{\partial \Phi}{\partial s_j} = \tau_j^0 + r \partial s_j \nu = (1 + r\lambda_j^0)\tau_j^0, \\
\frac{\partial \Phi}{\partial r} = \nu_0.
\]

Then one has that

\[
\frac{\partial \Phi}{\partial s_j} \cdot \frac{\partial \Phi}{\partial s_k} = \delta_{jk}(1 + r\lambda_j^0)^2, \quad j, k = 1, \ldots, n - 1, \\
\frac{\partial \Phi}{\partial s_j} \cdot \frac{\partial \Phi}{\partial r} = 0, \quad j = 1, \ldots, n - 1, \\
\frac{\partial \Phi}{\partial r} \cdot \frac{\partial \Phi}{\partial r} = 1.
\]

By assumption

\[
\max_{j=1, \ldots, n-1} |\lambda_j^0| \leq \Lambda < \infty \text{ on } \Gamma_0,
\]

and, consequently, \( D\Phi(y, r) \) is invertible for \( 0 \leq r < \tilde{r}_0 \) and some \( \tilde{r}_0 > 0 \) which is taken to coincide with \( r_0 \) without loss of generality. This holds independently of the point \( y \in \Gamma_0 \). Compactness and the inverse function theorem then imply that

\[
\Phi \big|_{r_0(y, r) \times (-r_0, r_0)}
\]

is a diffeomorphism onto its image and

\[
\bigcup_{l=1, \ldots, N} B_{\Gamma_0}(y_l, r_0) \supset \Gamma_0,
\]

for some \( N \in \mathbb{N} \) and \( y_l \in \Gamma_0, \ l = 1, \ldots, N \). It remains to make sure that hypersurface does not come close to itself (not in a local fashion, but rather in a global way) in order to obtain a global diffeomorphism. To that end, define

\[
\sigma_l = \inf_{y \in B_{\Gamma_0}(y_l, r_0)} d_{\mathbb{R}^n}(y, y_l)
\]

and reset \( r_0 \) to half of \( \sigma = \min_{l=1, \ldots, N} \sigma_l \). Then \( \Phi_{\Gamma_0 \times (-r_0, r_0)} \) is injective as desired. Indeed, if

\[
\Phi(y_1, r_1) = \Phi(y_2, r_2) = x \text{ for } (y_i, r_i) \in \Gamma_0 \times (-r_0, r_0), \quad i = 1, 2,
\]

then

\[
d_{\mathbb{R}^n}(y_1, y_2) \leq d_{\mathbb{R}^n}(y_1, x) + d_{\mathbb{R}^n}(x, y_2) < \sigma,
\]

so that \( y_1, y_2 \) must be in the same ball and thus coincide along with \( r_1 = r_2 \).

**Remark 2.3.** Observe that the above construction yields a foliation of the tubular neighborhood by \( \text{buc}^{1+\alpha} \) surfaces only, since it employs the normal of \( \Gamma_0 \).

**Remark 2.4.** The map \( \Phi \) defined in the above proof yields coordinates \( (y, r) \) in \( T_{r_0}(\Gamma_0) \). In these variables it holds that \( d((r, y), \Gamma_0) = r \) for the signed distance function to \( \Gamma_0 \). It readily follows that

\[
\nabla d(\cdot, \Gamma_0) = 1\frac{\partial}{\partial r} = \nu_0 \in \text{buc}^{1+\alpha}(T_{r_0}(\Gamma_0)),
\]

This shows that \( d(\cdot, \Gamma_0) \in \text{buc}^{2+\alpha}(T_{r_0}(\Gamma_0)) \). Moreover

\[
\Delta d(\cdot, \Gamma_0) = H_{\Gamma_0},
\]

where \( H \) is the mean curvature of \( \Gamma_0 \).
The next lemma gives a refined version of the above which preserves regularity.

**Lemma 2.5.** Given $\Gamma_0 \in \mathcal{M}^{2+\alpha}$, there is $r_0 > 0$ and hypersurfaces $\Gamma_r \in \mathcal{M}^{2+\alpha}$ for $r \in (-r_0, r_0)$ such that

$$\bigcup_{|r| < r_0} \Gamma_r$$

is an open neighborhood of $\Gamma_0$.

**Proof.** By Lemma 2.2 there is $\tilde{r}_0 > 0$ such that, given any $x \in T_{\tilde{r}_0}(\Gamma_0)$, there is one $(y, r) = (y(x), r(x))$ s.t. $x = y + r\nu_{\Gamma_0}(y)$.

In $T_{\tilde{r}_0}(\Gamma_0)$ define the field

$$\tilde{\nu}(x) = \nu_{\Gamma_0}(y(x)),$$

take a smooth cut-off function $\eta : \mathbb{R} \to \mathbb{R}$ with $0 \leq \eta \leq 1$, $\eta|_{[-\tilde{r}_0/2, \tilde{r}_0/2]} \equiv 1$, and $\eta|_{(-3\tilde{r}_0/4, 3\tilde{r}_0/4)} \equiv 0$, and set

$$\tilde{\nu}(x) = \begin{cases} \tilde{\nu}(x)\eta(r(x)), & x \in T_{\tilde{r}_0}(\Gamma_0), \\ 0, & x \notin T_{\tilde{r}_0}(\Gamma_0). \end{cases}$$

Then $\tilde{\nu} \in \text{buc}^{1+\alpha}(\mathbb{R}^n, \mathbb{R}^n)$ is a global vector field. Now take a compactly supported smooth mollifier $\psi_\delta$ and define

$$\nu_\delta = \psi_\delta \ast \tilde{\nu}$$

componentwise. It follows that $\nu_\delta \in \text{BUC}^\infty(\mathbb{R}^n, \mathbb{R}^n)$, that supp($\nu_\delta$) $\subset T_{\tilde{r}_0}(\Gamma_0)$, and that

$$\nu_\delta \to \nu(y(\cdot)) \text{ in } \text{buc}^{1+\alpha}(T_{\tilde{r}_0/2}(\Gamma_0)).$$

In particular

$$|\nu_\delta(y) \cdot \tau_{\Gamma_0}(y)| \leq c(\delta), \forall \tau_{\Gamma_0}(y) \in T_y \Gamma_0 \text{ with } |\tau_{\Gamma_0}(y)| = 1,$$

where $c(\delta) \to 0$, as $\delta$ tends to zero, uniformly in $y \in \Gamma_0$. The vector field is therefore uniformly transversal to $\Gamma_0$. Finally set

$$\Gamma_r = \varphi_\delta(\Gamma_0, r)$$

for the flow generated by the ode

$$\begin{cases} \dot{x} = \nu_\delta(x), \\ x(0) = y \in \Gamma_0. \end{cases}$$

It is easily seen that there is $r_0 > 0$ such that

$$\varphi_\delta(\Gamma_0, r) = \Gamma_r \subset T_{\tilde{r}_0}(\Gamma_0), |r| \leq r_0,$$

if $\delta << 1$, and standard ODE arguments yield that

$$\varphi_\delta : \Gamma_0 \times (-r_0, r_0) \to \bigcup_{r \in (-r_0, r_0)} \Gamma_r$$

is a diffeomorphism. \qed

The previous lemma provides coordinates $(y, r)$ for a neighborhood of $\Gamma_0$, which can be denoted by $T_{\tilde{r}_0}(\Gamma_0)$ since it is constructed starting with the smooth vector field $\nu_\delta$. Explicitly this means that

$$\forall x \in T_{\tilde{r}_0}(\Gamma_0) \exists (y, r) \text{ s.t. } x = \varphi_\delta(y, r).$$
Lemma 2.6. Let $\Gamma_0 \in \mathcal{M}^{j+\alpha}$, $j \geq 2$, and $\Gamma \in \mathcal{M}^{k+\alpha}$, $k \geq 1$, satisfy $d_{C^1}(\Gamma, \Gamma_0) << 1$. Then there is a unique $\rho \in buc^{k+\alpha}(\Gamma_0)$ such that

$$\Gamma = \{ \varphi^\delta(y, \rho(y)) \mid y \in \Gamma_0 \}.$$ 

In more suggestive terms, $\Gamma$ can be viewed as a $\nu^\delta$-graph (or a $\varphi^\delta$-graph) over $\Gamma_0$.

Proof. Without loss of generality assume that $j = 2$ and let $k = 2$ first. Given $\Gamma$ with the above properties, it immediately follows from Lemma 2.5 that, given any $x \in \Gamma$, there is a unique $(y(x), r(x)) \in \Gamma_0 \times (-r_0, r_0)$ such that

$$x = \varphi^\delta(y(x), r(x)).$$

The function $\rho(y)$ is then obtained by setting $\rho(y) = r(x)$ if $y = y(x)$. To show that it is well-defined and it has the required smoothness consider the map

$$d^\delta_{\Gamma} : \Gamma_0 \times (-r_0, r_0) \to \mathbb{R}, (y, r) \mapsto d(\varphi^\delta(y, r), \Gamma),$$

Observing that

$$\frac{\partial}{\partial r} d^\delta_{\Gamma}(y, r) = \nabla d(\varphi^\delta(y, r), \Gamma) \cdot \varphi^\delta_y(r, y),$$

where the dot means differentiation with respect to $r$, the assumption implies that

$$\nabla d(\varphi^\delta(y, r), \Gamma) = \nu^\delta_{\Gamma}(x) \simeq \nu_0(y)$$

if $\varphi^\delta(r, y) = x \in \Gamma$, and thanks to $\nabla d(\cdot, \Gamma) = \nu^\delta_{\Gamma}$ on $\Gamma$ (see Remark 2.4). Simultaneously

$$\varphi^\delta(r, y) = \nu^\delta(\varphi^\delta(r, y)) \simeq \nu_0(y).$$

It follows that $\frac{\partial}{\partial r} d^\delta_{\Gamma}(y, r) \neq 0$ where $\varphi^\delta(r, y) \in \Gamma$. The implicit function theorem now implies the existence of

$$\rho \in buc^{k+\alpha}(\Gamma_0)$$

s.t. $d_{\Gamma}(\varphi^\delta(y, \rho(y))) \equiv 0$,

as claimed. The graph representation is obtained locally at first. If it is extended to its maximal domain of validity, one can easily see that the latter is open and closed and, hence, coincides with the whole hypersurface $\Gamma_0$ thanks to the fact that it is connected. Assume next that $k = 1$. Approximate $\Gamma$ in $buc^{1+\alpha}$ by a family of $buc^{2+\alpha}$ hypersurfaces $(\Gamma^\eta)_{\eta \in (0,1]}$. This can be done, as for instance in [4], by solving

$$\begin{cases}
\Delta u = 1 & \text{in } \Omega, \\
u = 0 & \text{on } \Gamma = \partial \Omega,
\end{cases}$$

and setting $\Gamma^\eta = \{ u = \eta \}$. For each $\eta \in (0,1]$, by the first part of the proof, there is a function $\rho^\eta \in buc^{2+\alpha}(\Gamma_0)$ with the property that

$$\Gamma^\eta = (\varphi^\delta \circ (\text{id}, \rho^\eta))(\Gamma_0).$$

Now $d_{C^1}(\Gamma, \Gamma_0) << 1$, the fact that $\|\rho^\eta\|_{\infty} \leq \infty$ uniformly in $\eta$, and the $C^1$ convergence of $\Gamma^\eta$ to $\Gamma$ implies that necessarily

$$\|\rho^\eta\|_{\infty} + \|d\rho^\eta\|_{\infty} \leq c < \infty \text{ for } \eta \in (0,1],$$

for some positive constant $c$. If this were not the case, then at least one of the tangent vectors

$$\tau^\eta_j = d[\varphi^\delta \circ (\text{id}, \rho^\eta)](\tau^\eta_j) = (d\varphi^\delta \circ (\text{id}, \rho^\eta))(\tau^\eta_j) + [\nu^\delta \circ (\text{id}, \rho^\eta)] d\rho^\eta(\tau^\eta_j),$$

where $\tau^\eta_j$, $j = 1, \ldots, n$, is a basis of $TT\Gamma_0$, would eventually point, somewhere, in direction of $\nu^\delta \simeq \nu_0$. This follows from the fact that the first summand in the right-hand-side of (2.3) remains bounded by construction, while $\partial_j \rho^\eta = d\rho^\eta(\tau^\eta_j)$ would, for at least one $j$, tend to infinity in size along a sequence $(y_k)_{k \in \mathbb{N}}$ of points in $\Gamma_0$. As this sequence can be taken to converge to a point on $\Gamma_0$ without loss of generality, a contradiction would ensue to the assumption that $d_{C^1}(\Gamma, \Gamma_0) << 1$. 

The Arzelà-Ascoli Theorem then implies the existence of a continuous limiting function \( \rho_T : \Gamma_0 \rightarrow \mathbb{R} \) such that \( \rho_{\eta_k} \rightarrow \rho_T \), as \( k \rightarrow \infty \), for a sequence of indices \( (\eta_k)_{k \in \mathbb{N}} \). It must then hold that

\[
\Gamma = (\varphi^\delta \circ (\text{id}, \rho_T))(\Gamma_0)
\]

and that \( \rho \in \text{buc}^{1+\alpha}(\Gamma_0) \) due to the regularity of \( \varphi^\delta \) and that of \( \Gamma \) itself. \( \square \)

The above lemma shows that, given \( \rho \in \text{buc}^{2+\alpha} \) small enough (in the \( C^1 \) topology), the hypersurface

\[
\Gamma_\rho = \{ \varphi^\delta(y, \rho(y)) \mid y \in \Gamma_0 \}
\]

is well-defined.

It is important to have access to relevant geometric quantities for \( \Gamma_\rho \). Fix \( y \in \Gamma_0 \) and choose again coordinates \( s = (s_1, \ldots, s_{n-1}) \) along the principal directions of \( \Gamma_0 \) at \( y \) (just as in the proof of Lemma 2.2 and using the notation introduced there). One computes that

\[
\tilde{\tau}^\rho_j = \frac{\partial}{\partial s^j} \varphi^\delta \circ (\text{id}, \rho) = \partial_j \varphi^\delta \circ (\text{id}, \rho) + \dot{\varphi}^\delta \circ (\text{id}, \rho) \partial_j \rho \tag{2.4}
\]

is a tangent vector to \( \Gamma_\rho \) at \( \varphi^\delta(y, \rho(y)) \). Observe that the notation

\[
\partial_j g(y) = \langle d_y g, \tau^0_j \rangle, \quad y \in \Gamma_0
\]

was used in the above expressions for functions defined on \( \Gamma_0 \). For \( \delta << 1 \) one has that

\[
\frac{\partial}{\partial s^j} \varphi^\delta \circ (\text{id}, \rho) \simeq (1 + \lambda^0_j \rho) \tau^0_j + (\partial_j \rho) \nu_0,
\]

since

\[
\varphi^\delta(y, r) \simeq y + r \nu^\delta(y) \simeq y + r \nu_0(y).
\]

It can be concluded that

\[
\tilde{\tau}_1^\rho, \ldots, \tilde{\tau}_{n-1}^\rho
\]

is a basis of \( T_x \Gamma_\rho \) for \( x = \varphi^\delta(y, \rho(y)) \), provided that, as it is assumed, \( \rho \) is small in the \( C^1 \) topology.

3. Taking variations by Flows

Of interest is the dependence of various quantities on the domain/manifold on which they are defined. Fix a compact oriented hypersurface \( \Gamma_0 \in \mathcal{M}^{2+\alpha} \) and, for now, let \( F \) be any smooth section of a bundle over \( \mathcal{M}^{2+\alpha} \), which, in fact, can be assumed to be defined in a neighborhood \( \mathcal{U}^{2+\alpha} \) of \( \Gamma_0 \) only. In particular it will be useful to have a convenient way to compute \( \frac{d}{dt} \big|_{t=0} \Gamma \cdot F \). A natural way to do this is to fix a \( C^\infty \)-flow \( \varphi \) on \( \mathbb{R}^n \), that is, a smooth map

\[
\varphi : (-\varepsilon, \varepsilon) \times \mathbb{R}^n \rightarrow \mathbb{R}^n, \quad (s, x) \mapsto \varphi(s, x) =: \varphi_s(x),
\]

with \( \varphi_s \in \text{Diff}^\infty(\mathbb{R}^n) \) and satisfying

\[
\begin{cases}
\varphi_0 = \text{id}_{\mathbb{R}^n}, \\
\varphi_{s+\delta} = \varphi_s \circ \varphi_{\delta}, \quad s, \delta, s + \delta \in (-\varepsilon, \varepsilon).
\end{cases}
\]

and use it in order to generate a curve of hypersurfaces in \( \mathcal{U}^{2+\alpha} \) by setting

\[
\Gamma_s = \varphi_s(\Gamma_0), \quad s \in (-\varepsilon, \varepsilon).
\]

Then

\[
d\Gamma_0 F([\Gamma_s]) = [F \circ \Gamma] = [(\varphi^*_s F)(\Gamma_0)],
\]
where the superscript \( * \) denotes the pull-back and the square brackets are used to indicate the equivalence class of curves determined by the curve they contain. Proceeding in this way, it is natural to identify the tangent vector \( \Gamma \cdot \nu \) with the vector field
\[
\frac{d}{ds}igg|_{s=0} \varphi_s = \nu \varphi
\]
associated to the flow \( \varphi \).

**Remark 3.1.** Only the values of \( \nu \varphi \) on \( \Gamma_0 \) actually matter but it is convenient to think of the vector field being defined in at least a neighborhood of \( \Gamma_0 \) and sometimes everywhere. Observe that different vector fields can represent the same tangent vector, but, if two fields are in the same equivalence class, then they differ by a field tangential to \( \Gamma_0 \).

The following notation will be used from now on
\[
\langle d_{\Gamma_0} F, \nu \varphi \rangle = [\varphi^* F],
\]
for the tangential of the section \( F \) at \( \Gamma_0 \).

### 3.1. Examples.

(a) As a first example, consider \( F \) to be a smooth section of the Banach space “bundle”
\[
E = \coprod_{\Gamma \in \mathcal{U}^{2+\alpha}} \text{buc}^{2+\alpha}(\Gamma),
\]
where \( F \) is smooth at \( \Gamma_0 \) if \( [s \to F \circ \Gamma_s] \) is smooth for any smooth curve in \( \mathcal{U}^{2+\alpha} \). As a specific example, take \( f \in C^\infty(\mathbb{R}^n, \mathbb{R}^n) \) and define
\[
F(\Gamma) = f\bigg|_{\Gamma}.
\]
Then \( F \) is a smooth section and
\[
\langle d_{\Gamma_0} F, \nu \varphi \rangle = \left. \frac{d}{ds} \right|_{s=0} f \circ \varphi_s\bigg|_{\Gamma_0} = \nabla f \cdot \nu \varphi\bigg|_{\Gamma_0} = \partial_{\nu \varphi} f\bigg|_{\Gamma_0}.
\]

**Remark 3.2.** Since any \( \Gamma \) in the neighborhood \( \mathcal{U}^{2+\alpha} \) of \( \Gamma_0 \) is diffeomorphic to it, i.e., there is \( \varphi_\Gamma \in \text{Diff}^{2+\alpha}(\Gamma, \Gamma_0) \), such diffeomorphisms yield a local trivialization of \( E \) via
\[
\text{buc}^{2+\alpha}(\Gamma_0) \times \mathcal{U} \to E, \quad (g, \Gamma) \mapsto g \circ \varphi_\Gamma.
\]
Now, any diffeomorphism \( \varphi_\Gamma \) can be viewed as the restriction of a general flow \( \varphi \), thus providing additional justification for the approach via flows described above.

(b) Let \( f \in C^\infty(\mathbb{R}^n, \mathbb{R}^n) \) and consider
\[
\begin{cases}
-\Delta u = f & \text{in } \Omega, \\
u = 0 & \text{on } \Gamma = \partial \Omega,
\end{cases}
\]
and let
\[
F : \mathcal{U}^{2+\alpha} \to \coprod_{\Gamma \in \mathcal{U}^{2+\alpha}} \text{bvp}^2(\Gamma), \quad \Gamma \mapsto (-\Delta_\Gamma, \gamma_\Gamma, f)
\]
be the section of the “second order boundary value problems bundle” over \( \mathcal{U}^{2+\alpha} \) corresponding to the above boundary value problem. Then
\[
\langle d_{\Gamma_0} F, \nu \varphi \rangle = \left. \frac{d}{ds} \right|_{s=0} \left( \varphi_s^*(-\Delta_\Omega) \varphi_s^*, \varphi_s^* \gamma_\Gamma, \varphi_s^* f, \varphi_s^* f \right),
\]
where \( \varphi_s^* = (\varphi_s)^{-1} = (\varphi_s^{-1})^* \).

---

1The term is used in a somewhat loose way here in order to appeal to intuition. A formal justification would require additional work that is not necessary for the purposes of this paper.
Remark 3.3. Notice that, in this case, it is assumed that \( \varphi_s \) be defined everywhere so as to be able to transform the operator \(-\Delta\) defined on \( \Omega \). Observe also that there is nothing geometric (that is, no identification/trivialization is necessary) in pulling the problem back to the domain \( \Omega_0 \) since the original problem on \( \Omega_s \) is equivalent to

\[
\begin{align*}
-\varphi_s^* \circ \Delta \circ \varphi_s^* (v) &= \varphi_s^* f & \text{in } \Omega_0, \\
v &= 0 & \text{on } \Gamma_0,
\end{align*}
\]

for \( v = \varphi_s^* u \). This also provides justification for the use of the pull-back trivialization introduced earlier as it perfectly matches the definition of tangential by means of pull-backs. To be more explicit: if one is interested, as is the case here, in computing \( (d_{\varphi_s}u, \nu_\varphi) \), then one needs to consider \( \frac{d}{ds}|_{s=0} \varphi_s^* u \), which necessarily involves determining the solution \( v = \varphi_s^* u \) of (3.6).

Remark 3.4. Observe that, since only \( \nu_\varphi \big|_{\Gamma_0} \) matters, there arises great freedom in the choice of an extension of the vector field. This freedom leads to the intuition that, choosing the “trivial extension”, the interior of the problem should not have an influence on the domain variation other than through \( u_0 \), the solution in \( \Omega_0 \). More on this aspect later.

Returning to the example, one can describe how the solution \( u \) depends on \( \Gamma \) or, with moving boundary problems in mind, how \( \partial_\nu u \) depends on it. Fix a flow \( \varphi_s \) and solve (3.3) on \( \Omega_0 \) or (3.6) to obtain \( u = u(s) \) or \( v = v(s) = \varphi_s^* u(s) \), respectively. Then

\[
\frac{d}{ds}\bigg|_{s=0} \varphi_s^* u = \frac{d}{ds}\bigg|_{s=0} v(s),
\]

as remarked above. Define \( A(s) = -\varphi_s^* \Delta \varphi_s^* \) so that

\[
-\Delta (v \circ \varphi_s^{-1})(x) = (A(s)v)(\varphi_s^{-1}(x)), \quad x \in \Omega_s,
\]

for \( v : \Omega_0 \rightarrow \mathbb{R} \), where \( \Omega_0 \ni y = y_s(x) = \varphi_s^{-1}(x) \).

Using this notation it easily follows that

\[
A(s) = -\sum_{k,l=1}^n \left( \sum_{j=1}^n \frac{dy_j^k}{dx^j} \frac{dy_j^l}{dx^l} \right) \frac{\partial^2}{\partial y^k \partial y^l} - \sum_{l=1}^n \left( \sum_{j=1}^n \frac{\partial^2 y_j^l}{(\partial x^j)^2} \right) \frac{\partial}{\partial y^l}.
\]

Differentiating the equations yields

\[
\frac{d}{ds}\bigg|_{s=0} A(s) u_0 + A(0) \frac{d}{ds}\bigg|_{s=0} u(s) = \frac{d}{ds}\bigg|_{s=0} (f \circ \varphi_s) = \partial_\nu f \text{ in } \Omega_0,
\]

and that \( \frac{d}{ds}|_{s=0} u(s) = 0 \) on \( \Gamma_0 \). Next one needs an expression for \( \frac{d}{ds}|_{s=0} \) of the coefficients \( \frac{\partial \varphi_s^{-1}}{\partial x^j} \circ \varphi_s \) and \( \frac{\partial^2 \varphi_s^{-1}}{(\partial x^j)^2} \circ \varphi_s \).

Lemma 3.5. It holds that

\[
a_{kl} = -(D_{\nu s}^\top D_{\nu s})_{kl} \quad \text{and} \quad b_l = -\text{tr}(D^2_{\nu s}), \quad k, l = 1, \ldots, n
\]

for the vector field \( \nu_\varphi \) associated to the flow \( \varphi \).

Proof. It is plain that \( \varphi_s \circ \varphi_s^{-1} = \text{id} \) implies \( D\varphi_s^{-1} \circ \varphi_s = (D\varphi_s)^{-1} \). Then

\[
\begin{align*}
\varphi_s &= \nu_\varphi(\varphi_s), \\
\varphi_0 &= \text{id},
\end{align*}
\]
This yields
\[
\begin{align*}
D\varphi_s &= D\nu_\varphi(\varphi_s)D\varphi_s, \\
D\varphi_0 &= 1.
\end{align*}
\]

It follows that
\[
\frac{d}{ds}\bigg|_{s=0} (D\varphi_s^{-1} \circ \varphi_s) = -(D\varphi_s)^{-1}D\dot{\varphi}_s(D\varphi_s)^{-1}\bigg|_{s=0} = -D\dot{\varphi}_0 = -D\nu_\varphi.
\]

Next, the relation \( D\varphi_s^{-1} = (D\varphi_s)^{-1} \) entails that
\[
D(D\varphi_s^{-1}) = -(D\varphi_s)^{-1}D^2\varphi_s(D\varphi_s)^{-1}.
\]

It also holds that
\[
\begin{align*}
D(D\varphi_s) &= (D^2\varphi_s) \cdot D^2\nu_\varphi \circ \varphi_s(D\varphi_s) + D\nu_\varphi \circ \varphi_s D^2\varphi_s, \\
D^2\varphi_0 &= 0,
\end{align*}
\]

This yields
\[
\frac{d}{ds}\bigg|_{s=0} (D(D\varphi_s^{-1}) \circ \varphi_s) = -\frac{d}{ds}\bigg|_{s=0} (D\varphi_s)^{-1}D^2\varphi_0(D\varphi_0)^{-1} - (D\varphi_0)^{-1}D^2\varphi_0(D\varphi_0)^{-1} +
\]
\[
-\frac{d}{ds}\bigg|_{s=0} (D\varphi_0)^{-1}D^2\varphi_0(D\varphi_s)^{-1} = -D^2\nu_\varphi(1,1) = -D^2\nu_\varphi.
\]

The claim easily follows. \(\square\)

Summarizing one has that
\[
\begin{align*}
\mathcal{A}(0) &= -\Delta \text{ on } \Omega_0, \\
\frac{d}{ds}\bigg|_{s=0} \varphi_s^* f &= \partial_{\nu_\varphi} f = \nabla f \cdot \nu_\varphi, \\
\frac{d}{ds}\bigg|_{s=0} \mathcal{A}(0) &= \sum_{k,l=1}^n (D\nu_\varphi^T D\nu_\varphi)_{k,l} \frac{\partial^2}{\partial y^k \partial y^l} + \sum_{l=1}^n \text{tr}(D^2\nu_\varphi^l) \frac{\partial}{\partial y^l}.
\end{align*}
\]

Finally it is arrived at

**Theorem 3.6.** It holds that
\[
\frac{d}{ds}\bigg|_{s=0} \varphi_s^*(u(s)) = (-\Delta_{\Omega_0}, \gamma_{\Gamma_0})^{-1} \left( \nu_\varphi \cdot \nabla f - D\nu_\varphi^T D\nu_\varphi : D^2u_0 - \text{tr}(D^2\nu_\varphi) \cdot \nabla u_0, 0 \right),
\]

that is, the solution of the homogeneous Dirichlet problem with the given data.

In the above theorem the notation \( A : B \) was used for \( \text{tr}(A^T B) \) and symmetric matrices \( A, B \). Next consider \( \partial_{\nu_\varphi} u \). As the normal derivative is a function on the boundary, it is natural to expect \( \frac{d}{ds} \bigg|_{s=0} \partial_{\nu_\varphi} u \) not to depend on interior (to the domain \( \Omega_0 \)) information other than \( u_0 \) itself. Using representation (3.7), however, would seem to indicate that there be dependence on \( \varphi_s |_{\Omega_0} \) as well. It is therefore best to proceed in a slightly different way. Take \( u_0 \), the solution of (3.5) in \( \Omega_0 \), and assume, at first, that \( \varphi \) flows into \( \Omega_0 \), and look for \( u(s) = u_0 + \bar{u}(s) \). Then \( \bar{u} \) satisfies
\[
\begin{align*}
-\Delta \bar{u} &= 0 \quad \text{in } \Omega_s, \\
\bar{u} &= -u_0 |_{\Gamma_s} \quad \text{on } \Gamma_s
\end{align*}
\]

and, consequently one has that
\[
\partial_{\nu_\varphi} u(s) = \partial_{\nu_\varphi} u_0 + \partial_{\nu_\varphi} \bar{u}(s).
\]
Next observe that $\bar{u}(0) \equiv 0$ and that

$$\partial_{\nu_s} \bar{u}(s) = -DtN_{\Gamma_s}(u_0|_{\Gamma_s}),$$

where $DtN_{\Gamma}$ denotes the standard Dirichlet-to-Neumann operator of the domain $\Omega$ with boundary $\Gamma$. It can be concluded that

$$\frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} u(s)) = \left( \frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} u(s)) \cdot \nabla u_0 + \partial_{\nu_0} \frac{d}{ds}\bigg|_{s=0} \varphi_s^*(u_0|_{\Gamma_s}) + 
- \left( \frac{d}{ds}\bigg|_{s=0} \varphi_s^*DtN_{\Gamma_s}\varphi_s^*(u_0|_{\Gamma_s}) - DtN_{\Gamma_0}\left( \frac{d}{ds}\bigg|_{s=0} \varphi_s^*(u_0|_{\Gamma_s}) \right) \right)
= \partial_{\nu_0} \bar{u} - DtN_{\Gamma_0}(\partial_{\nu_0} u_0).$$

The first term vanishes in view of Lemma 4.3 below.

**Theorem 3.7.** It holds that

$$\langle d_{\Gamma_0}\partial_{\nu_s} u, \nu_\varphi \rangle = \frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} u(s)) = \partial_{\nu_0} \bar{u} - DtN_{\Gamma_0}(\partial_{\nu_0} u_0).$$

**Proof.** It remains to show that the claim is valid for a general flow $\varphi$. First choose an outward flow $\bar{\varphi}$ and define

$$\bar{\Omega}_\varepsilon = \varphi_\varepsilon(\Omega_0), \varepsilon > 0.$$

Then, given an arbitrary flow $\varphi$, it will hold that

$$\varphi_s(\Omega_0) \subset \bar{\Omega}_\varepsilon \text{ if } s \ll 1.$$

Denoting by $\bar{u}_\varepsilon$ the solution of (3.3) in $\bar{\Omega}_\varepsilon$, look for $u = \bar{u}_\varepsilon + \bar{w}$, so that $\bar{w}$ is harmonic in $\Omega_s$ and satisfies

$$\bar{w} = -\bar{u}_\varepsilon \text{ on } \Gamma_s,$$

at least for $s \ll 1$. Retracing the steps of the computation preceding the theorem, it is arrived at

$$\frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} u(s)) = \left( \frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} \bar{u}_\varepsilon) + 
- \left( \frac{d}{ds}\bigg|_{s=0} \varphi_s^*DtN_{\Gamma_s}\varphi_s^*(\bar{u}_\varepsilon|_{\Gamma_0}) - DtN_{\Gamma_0}\left( \frac{d}{ds}\bigg|_{s=0} \bar{u}_\varepsilon|_{\Gamma_s} \right) \right) \right).$$

As this last formula is valid for any $\varepsilon > 0$, it can be inferred that, letting $\varepsilon \to 0$, the claim is indeed valid since $\bar{u}_0 = u_0$ and thus $\bar{u}_0|_{\Gamma_0} \equiv 0$. \hfill \Box

This shows that, if $\frac{d}{ds}\bigg|_{s=0} \varphi_s^*(\partial_{\nu_s} u)$ is computed by means of Theorem 3.7 then its independence of $\varphi_s|_{\Omega_0}$ is obfuscated. There indeed would even appear a possible dependence on $D^2\nu_s$. This can make calculations for moving boundary problems less transparent and more cumbersome.

4. **Variations in a parametrized context**

For a given smooth flow $\varphi$ one always has that

$$\varphi_s(\Gamma_0) \subset T_{\nu_0}^s(\Gamma_0)$$

for $s \ll 1$. Then Lemma 2.6 implies that

$$\varphi_s(\Gamma_0) = \{ \varphi^s(y, \rho(s, y)) \mid y \in \Gamma_0 \} = \varphi^s \circ (\text{id}, \rho(s, \cdot))(\Gamma_0),$$

for some $\rho(s, \cdot) \in \text{buc}^{2+\alpha}(\Gamma_0)$. It follows that, in calculations, $\varphi_s$ can be replaced by

$$\varphi_\rho := \{ s \mapsto \varphi^s(\cdot, \rho(s, \cdot)) \}.$$
which is a family of diffeomorphisms tracing the same curve of hypersurfaces. Notice that
\[ d\varphi_\rho = d\varphi^\delta(\cdot, \rho) + \dot{\varphi}^\delta d\rho \]
clearly shows that these are, indeed, diffeomorphisms, provided \( \rho \) is small enough in the \( C^1 \)-topology. These “flows” differ merely in their (irrelevant) tangential action. It holds that
\[ \frac{d}{ds} \bigg|_{s=0} \varphi^\delta(\cdot, \rho(s, \cdot)) = \dot{\varphi}^\delta \rho(0, \cdot) =: \dot{\rho}_0 \nu^\delta \]
on \( \Gamma_0 \). If, on occasion, an extension to a flow on \( \mathbb{R}^n \), denoted by \( \Phi^\rho \), is needed, one can choose one of infinitely many extensions. Here, for the sake of definiteness, it is proceeded as follows: for \( x \in T^\rho_{\Gamma_0}(\Gamma_0)^c \) simply set
\[ \Phi^\rho_s(x) = \Phi^\rho(s, x) \equiv x, \quad s \in (-\varepsilon, \varepsilon), \]
while in \( T^\rho_{\Gamma_0}(\Gamma_0) \), using the coordinates \( x = (y(x), r(x)) \) given by Lemma 2.5 define
\[ \Phi^\rho_s(y, r) = \Phi^\rho((y, r), s) = (y, r + \rho(s, y)\eta(r)), \tag{4.10} \]
where \( \eta \) is a cut-off function of the type used in the proof of Lemma 2.5. Clearly \( \Phi^\rho \) is a family of diffeomorphisms, which is as smooth as \( \rho \) is, and
\[ \Phi^\rho_s|_{\Gamma_0} = \varphi^\delta \circ (\text{id}, \rho(s, \cdot)). \]
Again this rests on the assumption that \( \rho \) is small which makes the map \( [r \mapsto r + \rho(s, y)\eta(r)] \) invertible for fixed \( (s, y) \) thanks to its monotonicity.

**Remark 4.1.** In calculations it is often convenient to replace \( \rho(s, \cdot) \) by \( s\dot{\rho}_0 \) in the above definition as one obtains a curve of hypersurfaces that is, yes, different, but generates the same tangent vector.

The above considerations can be be summarized as follows

**Proposition 4.2.** It holds that
\[ T_{\Gamma_0}\mathcal{M}^{2+\alpha} \cong \text{buc}^{2+\alpha}(\Gamma_0), \]
where the superscript over the equal sign indicates an identification, which, in this case, is via the map
\[ h \mapsto h \dot{\varphi}^\delta = h \nu^\delta, \text{buc}^{2+\alpha}(\Gamma_0) \to \mathcal{M}^{2+\alpha} \]

**Proof.** Notice that
\[ \frac{d}{ds} \bigg|_{s=0} \varphi_s|_{\Gamma_0} = \nu^\delta|_{\Gamma_0}, \]
as well as that
\[ \frac{d}{ds} \bigg|_{s=0} \varphi^\delta \circ (\text{id}, \rho(s, \cdot)) = \nu^\delta|_{\Gamma_0} \dot{\rho}(0, \cdot). \]
Now, since \( \varphi_s \) and \( \varphi^\delta \circ (\text{id}, \rho(s, \cdot)) \) yield the same curve of hypersurfaces, the vector fields \( \nu^\delta|_{\Gamma_0} \) and \( \dot{\rho}_0 \nu^\delta|_{\Gamma_0} \) represent the same tangent vector and, since \( \varphi \) can be any flow, the whole tangent space can be generated in this way. Furthermore the fields \( \nu^\delta \) and \( \nu^\delta \) associated with two smooth flows \( \varphi \) and \( \tilde{\varphi} \) generating two distinct tangent vectors necessarily differ in their normal components at some point of \( \Gamma_0 \). In this case, their components in direction of the everywhere transversal field \( \nu^\delta \) will be different, too, showing that the map is injective. \( \square \)
4.1. Variations of the normal vector. Denote the unit outward normal to $\Gamma_\rho$ by $\nu_\rho$ for any given $\rho \in \text{buc}^{2+\alpha}(\Gamma_0)$. The preceding considerations and examples point to the necessity of computing $\langle d\Gamma, \nu_\Gamma, h\nu^\delta \rangle$. According to the above observations, this can be performed by evaluating $\frac{d}{ds}|_{s=0} \varphi^*_h \nu_{sh}$ for $h \in \text{buc}^{2+\alpha}(\Gamma_0)$

Lemma 4.3. It holds that

$$\frac{d}{ds}|_{s=0} \varphi^*_h \nu_{sh} = h \sum_{j=1}^{n-1} \langle d_y \nu^\delta(y), \tau^0_j \rangle |\nu_0| \tau^0_j - \langle \nu^\delta, |\nu_0| \rangle \sum_{j=1}^{n-1} \partial_j h \tau^0_j$$

that is, a differential operator of order 1 acting on $h$. Recall that, by construction, $\nu^0|_{\Gamma_0} = \nu_0 = \nu_{\Gamma_0}$.

Proof. The notation $\tilde{\tau}^\rho_j$, $j = 1, \ldots, n-1$ introduced in (2.4) is used here for a basis of tangent vectors in $T\Gamma_0$ and $\tau^0_j$, $j = 1, \ldots, n-1$ for their normalized counterparts. It then follows from $|\nu_{sh}| = 1$ and $\tau^{sh}_j \cdot \nu_{sh} = 0$ for $j = 1, \ldots, n-1$

that

$$\left( \frac{d}{ds}|_{s=0} \nu_{sh} \right) \cdot \tau^{sh}_j = - \left( \frac{d}{ds}|_{s=0} \tau^{sh}_j \right) \cdot \nu_{sh}$$

$$\left( \frac{d}{ds}|_{s=0} \nu_{sh} \right) \cdot \nu_{sh} = 0.$$

Evaluating in $s = 0$ yields

$$\frac{d}{ds}|_{s=0} \nu_{sh} = - \sum_{j=1}^{n-1} \left( \frac{d}{ds}|_{s=0} \tau^{sh}_j \right) \cdot \nu_0 \tau^0_j,$$

where, by design, $\tau^0_j$, $j = 1, \ldots, n-1$ is a basis of $T\Gamma_0$. Thus it is enough to compute $\frac{d}{ds}|_{s=0} \tau^{sh}_j$ for $j = 1, \ldots, n-1$ in order to compute $\frac{d}{ds}|_{s=0} \nu_{sh}$. Next observe that

$$\left\langle \tau^{sh}_j \cdot \tilde{\nu}_{\tau}^0, \nu_\rho \right\rangle = \frac{1}{|\tau^0_j|} \left( \frac{d}{ds}|_{s=0} \tilde{\tau}^{sh}_j \cdot \tau^0_j \right) \cdot \nu_0 \tau^0_j + |\tau^0_j| \left( \frac{d}{ds}|_{s=0} \tilde{\tau}^{sh}_j \right) \cdot \tau^0_j,$$

where $\tilde{\tau}^{sh}_j = \tau^0_j$ is a unit vector for $j = 1, \ldots, n-1$. Consequently one has that

$$\left\langle \tilde{\tau}^{sh}_j \cdot \nu_{sh}, \nu_\rho \right\rangle = \left\langle \tilde{\nu}_{\tau}^0, \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho, \quad j = 1, \ldots, n-1,$$

which shows that it is, in fact, enough to compute $\frac{d}{ds}|_{s=0} \tilde{\tau}^{sh}_j$ for $j = 1, \ldots, n-1$. Now

$$\left\langle \tilde{\tau}^{sh}_j \cdot \nu_{sh}, \nu_\rho \right\rangle = \left\langle \tilde{\nu}_{\tau}^0, \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho$$

$$= \left\langle \langle d_y \phi^\delta(y), \tau^0_j \rangle \cdot \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho, \quad j = 1, \ldots, n-1,$$

for $j = 1, \ldots, n-1$, and then

$$\left\langle \tilde{\tau}^{sh}_j \cdot \nu_{sh}, \nu_\rho \right\rangle = \left\langle \langle d_y \phi^\delta(y), \tau^0_j \rangle \cdot \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho$$

$$= \left\langle \langle d_y \phi^\delta(y), \tau^0_j \rangle \cdot \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho, \quad j = 1, \ldots, n-1.$$

Finally

$$\left\langle \tilde{\tau}^{sh}_j \cdot \nu_{sh}, \nu_\rho \right\rangle = \left\langle \langle d_y \phi^\delta(y), \tau^0_j \rangle \cdot \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho$$

$$= \left\langle \langle d_y \phi^\delta(y), \tau^0_j \rangle \cdot \nu_\rho \right\rangle \cdot \tilde{\tau}^{sh}_j \cdot \tau^0_j \cdot \nu_\rho, \quad j = 1, \ldots, n-1.$$
and thus
\[
\frac{d}{ds} \bigg|_{s=0} \nu_{sh} = \left( \sum_{j=1}^{n} (d_y \nu^\delta(y), \tau_j^0) \cdot \nu_0 \right) h \tau_j^0 - (\nu^\delta \cdot \nu_0) \sum_{j=1}^{n-1} (\partial_j h) \tau_j^0
\]
as claimed.

**Remark 4.4.** Notice that \( \langle d_y \nu^\delta(y), \tau_j^0 \rangle \approx \lambda_j \tau_j^0 \) for \( \delta \simeq 0 \) since \( \nu^\delta \simeq \nu_0 \). Recall that \( \lambda_j \) are the principal curvatures of \( \Gamma \).

If \( \rho(t, \cdot) \) is a time dependent function, then one can compute the velocity \( V \) in normal direction of the corresponding domains \( \Gamma_{\rho(t, \cdot)} \). This is clearly an important quantity for moving boundary problems. One has
\[
V(y) = \frac{d}{dt} \varphi^\delta(y, \rho(t, y)) \cdot \nu_{\rho(t, y)} = \left[ \frac{d}{dt} \varphi^\delta(y, \rho(t, y)) \right] \cdot \rho(t, y) = \left[ (\nu^\delta \circ \varphi^\delta)(y, \rho(t, y)) \cdot \nu_{\rho(t, y)} \right] \rho(t, y),
\]
for \( y \in \Gamma_0 \), i.e. \( \varphi^\delta(y, \rho(t, y)) \in \Gamma_{\rho} \).

or, for short, \( V = (\nu^\delta \cdot \nu_\rho) \rho_t \). Notice that
\[
(\nu^\delta \circ \varphi^\delta \circ (id, sh)) \cdot \nu_{sh} = \langle dv^\delta, \nu^\delta \rangle \cdot \nu_0 h
\]
\[
+ \sum_{j=1}^{n-1} (\nu^\delta \cdot \tau_j^0)(\langle d_y \nu^\delta(y), \tau_j^0 \rangle \cdot \nu_0) h - \sum_{j=1}^{n-1} (\nu^\delta \cdot \nu_0)(\nu^\delta \cdot \tau_j^0) \partial_j h
\]
uniformly in \( y \in \Gamma_0 \), if \( \delta << 1 \) and \( t \simeq 0 \).

**Lemma 4.5.** It holds that
\[
\frac{d}{ds} \bigg|_{s=0} \nu^\delta \circ \varphi^\delta \circ (id, sh) \cdot \nu_{sh} = \langle dv^\delta, \nu^\delta \rangle \cdot \nu_0 h
\]
\[
+ \sum_{j=1}^{n-1} (\nu^\delta \cdot \tau_j^0)(\langle d_y \nu^\delta(y), \tau_j^0 \rangle \cdot \nu_0) h - \sum_{j=1}^{n-1} (\nu^\delta \cdot \nu_0)(\nu^\delta \cdot \tau_j^0) \partial_j h
\]

**Proof.** A direct computation using Lemma 4.3 gives that the desired variation amounts to
\[
\langle dv^\delta, \frac{d}{ds} \bigg|_{s=0} \varphi^\delta \cdot \nu_0 \rangle + \frac{d}{ds} \bigg|_{s=0} \nu_{sh} = \left[ \langle dv^\delta, \nu^\delta \rangle \cdot \nu_0 h - \sum_{j=1}^{n-1} (\nu^\delta \cdot \nu_0)(\nu^\delta \cdot \tau_j^0) \partial_j h \right]
\]
as stated.

**Remark 4.6.** Notice that, when \( \delta << 1 \), one has that
\[
\langle dv^\delta, \nu^\delta \rangle \simeq 0, \nu^\delta \cdot \tau_j^0 \simeq 0, \text{ and } \nu^\delta \cdot \nu_0 \simeq 1,
\]
uniformly on \( \Gamma_0 \). It should also be pointed out that this variation vanishes if \( \delta \) can be set to zero.

**4.2. Examples Revisited.** It is of course possible to interpret the variation of the solution of a boundary value problem as in Example (b) of Section 3.1 in terms of the identification of Proposition 4.2.

**Corollary 4.7.** Given a smooth flow \( \varphi \), let \( \varphi_{sh} \) be the corresponding equivalent curve of diffeomorphisms introduced just before Proposition 4.2. Then it is already known that \( \nu_\varphi \) in 3.7 can be replaced by \( h^\nu \). The additional terms \( D\nu_\varphi \) and \( D^2 \nu_\varphi \) can be replaced by
\[
D(h \nu_0^\varphi)(x) = (h \circ y)(x)D\nu_\varphi^0(x) + D(h \circ y)(x)\nu_\varphi^0(x)
\]
and
\[
D^2(h \nu_0^\varphi)(x) = (h \circ y)(x)D^2\nu_\varphi^0(x) + 2D\nu_\varphi^0(x)D(h \circ y)(x) + D^2(h \circ y)(x)\nu_\varphi^0(x),
\]
respectively. Notice that, since \( h : \Gamma_0 \to \mathbb{R} \) depends on \( y \) only, all of its non vanishing derivatives are tangential ones.

**Remark 4.8.** The corollary shows how convenient it is to think in terms of flows or curves of diffeomorphisms: calculations can be performed in \( \mathbb{R}^n \) and not on the surface. Eventually one can replace the generic flow with a parametrized one by means of Proposition 4.2 and the coordinates of Lemma 2.2 to obtain concrete expressions in terms of the parameter function \( \rho \). Recall that \( h = \dot{\rho}(0, \cdot) \).

**Remark 4.9.** It should be pointed out that, when the surface \( \Gamma_0 \) is smooth, then \( \delta \) can be chosen to vanish (no regularization needed). In that case \( \nu_0^\delta|_{\Gamma_0} = \nu_0 \), and consequently, the terms \( D\nu_0 \) and \( D^2\nu_0 \) have geometric interpretations. E.g. \( D\nu_0 \) contains information about the curvatures of \( \Gamma_0 \) and its Christoffel symbols.

5. Moving Boundary Problems

Two well-known classical moving boundary problems are the Stefan and the Hele-Shaw problems. They are used in this section as prototypical examples to illustrate the benefits of the linearization approach described in the preceding sections which include conciseness and transparency.

5.1. **Hele-Shaw type problem.** Consider the system

\[
\begin{aligned}
-\Delta u &= f \quad \text{in } \Omega(t) \text{ for } t > 0, \\
0 &= \text{on } \Gamma(t) \text{ for } t > 0, \\
V &= -\partial_{v\nu} u \quad \text{on } \Gamma(t) \text{ for } t > 0, \\
0 &= \text{on } \Gamma(0) = \Gamma_0,
\end{aligned}
\]

for \( \Gamma_0 \in \text{buc}^{2+\alpha} \). Then one has the following

**Proposition 5.1.** The linearization of (5.11) in \((u(t), \Gamma(t)) \equiv (u_0, \Gamma_0)\), where clearly \( u_0 \) is the solution of the Poisson equation with homogeneous Dirichlet condition in \( \Omega_0 \), is given by

\[
\begin{aligned}
-\Delta \tilde{w} &= 0 \quad \text{in } \Omega_0, \text{ for } t > 0, \\
\tilde{w} &= -\partial_{v\nu} u_0 \quad \text{on } \Gamma_0 \text{ for } t > 0, \\
\dot{\nu}_\varphi \cdot \nu_0 &= -\partial_{v\nu_0} \partial_{v\varphi} u_0 - \partial_{v\nu_0} \tilde{w} \quad \text{on } \Gamma_0 \text{ for } t > 0, \\
\nu_\varphi(0) &= 0,
\end{aligned}
\]

where \( \nu_\varphi \) denotes the time dependent variation vector field used to infinitesimally deform \( \Gamma_0 \) and \( \dot{\nu}_\varphi \) its time derivative (see proof below for more detail). In particular, if

\( \nu_\varphi = h \nu_0^\delta \), then \( \dot{\nu}_\varphi = \dot{h} \nu_0^\delta \),

and (5.12) reduces to

\[
\begin{aligned}
-\Delta \dot{w} &= 0 \quad \text{in } \Omega_0, \text{ for } t > 0, \\
\dot{w} &= -(\partial_{v\nu_0} u_0) h \quad \text{on } \Gamma_0 \text{ for } t > 0, \\
(\nu_0^\delta \cdot \nu_0) \dot{h} &= -(\partial_{v\nu_0} \partial_{v\varphi} u_0) h - \partial_{v\nu_0} \tilde{w} \quad \text{on } \Gamma_0 \text{ for } t > 0, \\
\dot{h}(0, \cdot) &= 0 \quad \text{on } \Gamma_0.
\end{aligned}
\]

**Remark 5.2.** If \( f \geq 0 \), the strong maximum principle implies that

\( \partial_{v\nu_0} u_0 > 0 \),

and consequently the same inequality holds for \( \partial_{v\nu_0} u_0 \) since \( \delta \) can be chosen arbitrarily small. This can be used to show that the operator

\( h \mapsto \text{DtN}_{\Gamma_0}((\partial_{v\nu_0} u_0) h), \text{buc}^{2+\alpha}(\Gamma_0) \to \text{buc}^{1+\alpha}(\Gamma_0) \)
generates an analytic semigroup as required by maximal regularity theory to obtain a solution of the corresponding nonlinear problem. In this case the linearized system reduces to the single equation
\[(\nu^\delta \cdot \nu_0) \dot{h} = DtN_{\Gamma_0}((\partial_{\nu^\delta} u_0) h) - (\partial_{\nu^\delta} \partial_{\nu^\delta} u_0) h.\]

**Remark 5.3.** Whenever \(f \in C^\infty(\mathbb{R}^n, \mathbb{R}^n)\), one has that
\[\partial_{\nu^\delta} u_0 \in \text{buc}^{2+\alpha}.\]

This regularity is needed to ensure that multiplication with this normal derivative of \(u_0\) is a continuous operation on \(\text{buc}^{2+\alpha}(\Gamma_0)\) and then obtain the generation result of the previous remark.

**Proof.** Observe that
\[
\Delta (\partial_{\nu^\delta} u_0) = \Delta (\nu^\delta \cdot \nabla u_0) = \sum_{j=1}^n \partial^2_j (\nu_j^\delta \partial_j u_0)
\]

and that
\[\partial_{\nu^\delta} \partial_{\nu^\delta} u_0 = \nu_j^\delta \partial_j \left( (\nu^\delta \cdot \nu_0) \nu_j^\delta \partial_j u_0 + \sum_{j=1}^{n-1} (\nu^\delta \cdot \nu_0) \nu_j^\delta \partial_j u_0 \right) = \partial_{\nu^\delta} (\nu^\delta \cdot \nu_0) \partial_{\nu^\delta} u_0 + (\nu^\delta \cdot \nu_0) \partial_{\nu^\delta} u_0 = (\partial_{\nu^\delta} \nu^\delta \cdot \nu_0) \partial_{\nu^\delta} u_0 - (\nu^\delta \cdot \nu_0) f \in \text{buc}^{1+\alpha}(\Gamma_0),\]

and then obtain the generation result of the previous remark.

**Proof.** (of Proposition 5.1) Take a two parameter family of diffeomorphisms \(\varphi_{s,t}\) such that
\[\varphi_{0,t} \big|_{\Gamma_0} \equiv \text{id}_{\Gamma_0}\]

and set
\[\nu_\varphi = \left. \frac{d}{ds} \varphi_{s,t} \right|_{s=0} \text{ as well as } \dot{\nu}_\varphi = \left. \frac{d}{dt} \frac{d}{ds} \varphi_{s,t} \right|_{s=0}.\]

As follows from the proof of Proposition 4.2, it is possible to assume without loss of generality that the diffeomorphisms “flow” into \(\Omega_0\). Then rewrite (5.11) as
\[
\begin{cases}
-\Delta \bar{u} = 0 & \text{in } \Omega_{s,t} \text{ for } t > 0, \\
\bar{u} = -u_0 |_{\Gamma_{s,t}} & \text{on } \Gamma_{s,t} \text{ for } t > 0, \\
V = -\partial_{\nu^\delta} \varphi_{s,t}(u_0 + \bar{u}) & \text{on } \Gamma_{s,t} \text{ for } t > 0, \\
\Gamma(0) = \Gamma_0.
\end{cases}
\]

for \(u = u_0 + \bar{u}\), where, again, \(u_0\) is the solution of Poisson equation on \(\Omega_0\) with homogeneous Dirichlet condition on the boundary and
\[\Omega_{s,t} = \varphi_{s,t}(\Omega_0) \text{ and } \Gamma_{s,t} = \varphi_{s,t}(\Gamma_0).\]

Then
\[
\begin{cases}
-\mathcal{A}(s) \bar{\nu} = -\varphi_{s,t}^* \Delta \varphi_{s,t}^\delta \bar{v} = 0 & \text{in } \Omega_0 \text{ for } t > 0, \\
\bar{v} = -\varphi_{s,t}^* \left( u_0 |_{\Gamma_{s,t}} \right) & \text{on } \Gamma_0 \text{ for } t > 0,
\end{cases}
\]

\[\square\]
for \( \bar{v} = \varphi_{s,t}^* \bar{u} \) and
\[
V = \frac{d}{dt} \varphi_{s,t}^* \cdot \varphi_{s,t}^* \nu_{\Gamma_{s,t}} = -\varphi_{s,t}^* \left[ \partial_{\nu_{s,t}^*} u_0 \big|_{\Gamma_{s,t}} + \partial_{\nu_{s,t}^*} \bar{u} \right] \text{ on } \Gamma_0 \text{ for } t > 0.
\]
Taking a variation in \( s \) and evaluating in \( s = 0 \) yields
\[
\begin{align*}
-\mathcal{A}(0) \bar{w} - \frac{d}{ds} \big|_{s=0} \mathcal{A}(\nu) \big|_{s=0} &= 0 \text{ in } \Omega_0 \text{ for } t > 0, \\
\bar{w} &= -\partial_{\nu_{s,t}} u_0 \text{ on } \Gamma_0 \text{ for } t > 0,
\end{align*}
\]
and
\[
\nu_{\varphi} \cdot v_0 + 0 \cdot \frac{d}{ds} \big|_{s=0} \varphi_{s,t}^* \nu_{\Gamma_{s,t}} = -\partial_{\nu_{s,t}} \partial_{\nu_{s,t}} u_0 - \partial_{\nu_{s,t}} \bar{w} \text{ on } \Gamma_0 \text{ for } t > 0,
\]
for \( \bar{w} = \frac{d}{ds} \big|_{s=0} \bar{v} \) since \( \frac{d}{dt} \varphi \big|_{s=0} = 0 \). This system reduces to the claimed one at the end of the proposition if
\[
\nu_{\varphi} = h(t) \nu^\delta \text{ and } \nu_{\varphi} = \dot{h}(t) \nu^\delta.
\]
Just use Lemma 2.5 to replace the generic curve of diffeomorphisms with the equivalent \( \Phi_{s,t}^\rho \), introduced in (4.10) based on
\[
\Phi_{s,t}^\rho \big|_{s=0} = \varphi^\delta \circ (\text{id}, \rho(s,t,\cdot)),
\]
satisfying
\[
\Omega_{s,t} = \Phi_{s,t}^\rho(\Omega_0) \text{ and } \Gamma_{s,t} = \Phi_{s,t}^\rho(\Gamma_0),
\]
and such that \( \frac{d}{ds} \big|_{s=0} \rho(0, t, \cdot) = h(t, \cdot) \) and \( \frac{d}{ds} \big|_{s=0} \dot{\rho}(0, t, \cdot) = \dot{h}(t, \cdot). \)

Using known results for nonlinear evolution equations \([8, 9]\) one readily obtains classical local well-posedness results for (5.11).

5.2. A Stefan type problem. Consider the system
\[
\begin{align*}
\begin{cases}
 u_t - \Delta u &= f \text{ in } \Omega(t) \text{ and } t > 0, \\
u &= 0 \text{ on } \Gamma(t) \text{ and } t > 0, \\
u(0, \cdot) &= u_0 \text{ in } \Omega_0, \\
 V &= -\partial_{\nu_{s,t}} u \text{ on } \Gamma(t) \text{ and } t > 0, \\
 \Gamma(0) &= \Gamma_0,
\end{cases}
\end{align*}
\]
for \( \Gamma_0 \in \text{buc}^{2+\alpha} \) and \( u_0 \in \text{buc}^{2+\alpha}(\Omega_0) \).

Proposition 5.4. The linearization of (5.13) in
\[
(u(t, \cdot), \Gamma(t)) \equiv (u_0, \Gamma_0)
\]
is given by
\[
\begin{align*}
\begin{cases}
 \bar{w}_t - \Delta \bar{w} &= 0 \text{ in } \Omega_0 \text{ for } t > 0, \\
 \bar{w} &= -\partial_{\nu_{s,t}} u_0 \text{ on } \Gamma_0 \text{ for } t > 0, \\
 \bar{w}(0, \cdot) &= 0 \text{ in } \Omega_0, \\
 v_0 \cdot \nu_{\varphi} &= -\partial_{\nu_{s,t}} \partial_{\nu_{s,t}} u_0 - \partial_{\nu_{s,t}} \bar{w} \text{ on } \Gamma_0 \text{ for } t > 0, \\
 \nu_{\varphi}(0, \cdot) &= 0 \text{ on } \Omega_0,
\end{cases}
\end{align*}
\]
Again, this reduces, in coordinates, to a system for \( (\bar{w}, h) \) via
\[
\partial_{\nu_{s,t}} u_0 = (\partial_{\nu_{s,t}} u_0) \text{ and } v_0 \cdot \nu_{\varphi} = (v^\delta \cdot v_0) \hat{h}
\]
for \( \nu_{\varphi} = h \nu^\delta \).
Proof. Proceeding as in the previous subsection by means of a two parameter family of diffeomorphisms, the only change in the calculations is caused by the time derivative of $u$. In this case the initial boundary value problem for $u$ is equivalent to
\[
\begin{align*}
\varphi^*_s,t \circ (\partial_t - \Delta) \circ \varphi^*_{s,t} (\bar{v}) &= 0 & \text{in } \Omega_0 \text{ for } t > 0, \\
\bar{v} &= -\varphi^*_{s,t} (u_0) \big|_{\Gamma_{s,t}} & \text{on } \Gamma_0 \text{ for } t > 0, \\
\bar{v}(0, \cdot) &= 0 & \text{in } \Omega_0,
\end{align*}
\]
where, again,
\[
\varphi^*_{s,t} v = u_0 + \varphi^*_{s,t} \bar{v} = u_0 + \bar{u}.
\]
Now
\[
\varphi^*_{s,t} \partial_t \varphi^*_{s,t} \bar{v} = \partial_t \bar{v} + \varphi^*_{s,t} \left( \left( \varphi^*_{s,t} \nabla \bar{v} \right) \frac{d}{dt} \varphi_{s,t}^{-1} \right) = \partial_t \bar{v} + \nabla \bar{v} \cdot V(s, t),
\]
for $V(s, t) = \varphi^*_{s,t} \varphi_{s,t}^{-1}$. Consequently one has that
\[
\left. \frac{d}{ds} \right|_{s=0} \left( \partial_t \bar{v} + \nabla \bar{v} \cdot V(s, t) \right) = \partial_t \left( \left. \frac{d}{ds} \right|_{s=0} \bar{v} \right) + \nabla \left( \left. \frac{d}{ds} \right|_{s=0} \bar{v} \right) \cdot V(0, t) + \nabla \bar{v}(0) \cdot \left. \frac{d}{ds} \right|_{s=0} V(s, t) = \partial_t \bar{w},
\]
for $\bar{w} = \left. \frac{d}{ds} \right|_{s=0} \bar{v}$ since
\[
V(0, t) = \varphi^*_{0,t} \left( \left. \frac{d}{dt} \varphi_{0,t}^{-1} \right) = 0,
\]
in view of $\varphi^*_{0,t} = \varphi_{0,t} = \text{id}_{\Gamma_0}$ for all $t$. The claim then follows using Proposition 5.12 $\square$

Remark 5.5. If the compatibility conditions
\[-\Delta u_0 = 0 \text{ in } \Omega_0 \text{ and } u_0 = 0 \text{ on } \Gamma_0,
\]
are satisfied, it is again possible to apply optimal regularity results to the nonlinear system for $(u, \rho)$ to obtain local in time well-posedness for (5.13) in the framework of classical regularity as well as long time existence and stability of stationary solutions.

Remark 5.6. In the described approach one can think of a solution, as far as $\Gamma(t)$ is concerned, as a curve of diffeomorphisms $\varphi_t$. In order to deal with the whole system, it is convenient to think of these as acting on the whole space. A nice benefit of the linearization procedure advocated here is that it makes it apparent that the final result does only depend on $\nu \varphi_t \big|_{\Gamma_0}$, as it could be expected based on geometric intuition.
