Abstract. We study the curvaton scenario using gauge-invariant second order perturbation theory and solving the governing equations numerically. Focusing on large scales we calculate the non-linearity parameter $f_{NL}$ in the two-fluid curvaton model and compare our results with previous analytical studies employing the sudden decay approximation. We find good agreement of the two approaches for large curvaton energy densities at curvaton decay, $\Omega_{\sigma_{\text{dec}}}$, but significant differences of up to 10% for small $\Omega_{\sigma_{\text{dec}}}$.

Keywords: cosmological perturbation theory, inflation

ArXiv ePrint: astro-ph/0604387
1. Introduction

The third year WMAP data release [1] has confirmed beautifully the cosmological standard model of structure formation: during inflation, fluctuations in the scalar fields are stretched to super-horizon scales and later on source the Cosmic Microwave Background (CMB) anisotropies and the large scale structure. In the standard inflation models the scalar field responsible for the accelerated expansion of the universe, the inflaton, also provides these fluctuations [2]. Recently, a related but different scenario has become popular: the curvaton paradigm [3]–[12]. Here the fluctuations are not generated by the inflaton, but by a different scalar field, the curvaton.

A powerful tool to differentiate between different models of the early universe is second order perturbation theory [13]–[33]. It allows the accurate calculation of higher order statistics such as the primordial bispectrum and the non-linearity parameter $f_{\text{NL}}$. Instead of using cosmological perturbation theory at second order, the $\Delta N$-formalism [34]–[39] has proved useful to study non-Gaussianity and calculate $f_{\text{NL}}$. 

Journal of Cosmology and Astroparticle Physics 09 (2006) 008 (stacks.iop.org/JCAP/2006/i=09/a=008)
Bartolo et al [20] studied the curvaton model at second order using cosmological perturbation theory, and Lyth and Rodriguez used the $\Delta N$-formalism to calculate the non-linearity parameter $f_{\text{NL}}$ in this scenario. However, both studies used the sudden decay approximation. Here we go beyond sudden decay, using second order gauge-invariant perturbation theory, and solve the ensuing equations numerically.

We consider scalar perturbations up to and including second order and assume a flat Friedmann–Robertson–Walker (FRW) background spacetime. We work on large scales (compared to the horizon size), which allows us to neglect gradient terms.

The outline of the paper is as follows. In the next section we give the governing equations up to second order and define the gauge-invariant variables we are using. We specify in section 3 the two-fluid curvaton model we are studying and apply the equations of section 2. In section 4 we take a small detour from perturbation theory and compare our perturbative approach to the $\Delta N$ formalism. After defining the non-linearity parameter $f_{\text{NL}}$ we present numerical solutions in section 5 and compare our numerical results to the sudden decay approximation. The governing equations without any gauge restrictions are given in the appendix.

2. Governing equations

In this section we give the governing equations for a system of multiple interacting fluids on large scales, allowing for scalar perturbations up to second order, following closely the treatment of [23] and [40].

The covariant Einstein equations are given by

$$G_{\mu\nu} = 8\pi G T_{\mu\nu},$$

(2.1)

where $G_{\mu\nu}$ is the Einstein tensor, $T_{\mu\nu}$ is the total energy–momentum tensor, and $G$ is Newton’s constant. Through the Bianchi identities, the field equations (2.1) imply the local conservation of the total energy and momentum,

$$\nabla_\mu T^{\mu\nu} = 0.$$  

(2.2)

In the multiple fluid case the total energy–momentum tensor is the sum of the energy–momentum tensors of the individual fluids

$$T^{\mu\nu} = \sum_\alpha T^{\mu\nu}_\alpha.$$  

(2.3)

For each fluid we define the local energy–momentum transfer four-vector $Q^{\nu}_\alpha$ through the relation

$$\nabla_\mu T^{\mu\nu}_\alpha = Q^{\nu}_\alpha,$$  

(2.4)

where energy–momentum is locally conserved for $Q^{\nu}_\alpha = 0$, i.e. only for non-interacting fluids. Equations (2.2) and (2.4) imply the constraint

$$\sum_\alpha Q^{\nu}_\alpha = 0.$$  

(2.5)

1 Notation: Greek indices, $\mu, \nu, \lambda$, run over $0, \ldots, 3$, while lower case Latin indices, $i, j, k$, run over $1, \ldots, 3$. Greek indices from the beginning of the alphabet, $\alpha, \beta, \gamma$, will be used to denote different fluids.
We split scalar perturbations into background, first, and second order quantities according to
\[ \rho(x^\mu) \equiv \rho_0(t) + \delta\rho_1(x^\mu) + \frac{1}{2}\delta\rho_2(x^\mu), \]  \hspace{1cm} (2.6)
using here the total energy density as an example.

The line element on large scales is given by
\[ ds^2 = -\left[1 + 2(\phi_1 + \frac{1}{2}\phi_2)\right] dt^2 + a^2 \left[1 - 2(\psi_1 - \frac{1}{2}\psi_2)\right] \delta_{ij} dx^i dx^j, \]  \hspace{1cm} (2.7)
where \( a = a(t) \) is the scale factor, \( \phi_1 \) and \( \phi_2 \) are the lapse functions at first and second order, respectively, and \( \psi_1 \) and \( \psi_2 \) the curvature perturbations.

Following references [40, 41] we split the energy–momentum transfer four-vector using the total fluid velocity \( u^\mu \) as
\[ Q^\mu_{(\alpha)} \equiv Q_{(\alpha)}u^\mu + f^\mu_{(\alpha)}, \]  \hspace{1cm} (2.8)
where \( Q_{(\alpha)} \) is the energy transfer rate and \( f^\mu_{(\alpha)} \) the momentum transfer rate, subject to the condition \( u_\mu f^\mu_{(\alpha)} = 0 \).

On large scales the only non-zero component of the four-velocity is
\[ u_0 = -\left[1 + \phi_1 + \frac{1}{2}\phi_2 - \frac{1}{4}\phi_1^2\right], \]  \hspace{1cm} (2.9)
subject to the constraint \( u_\mu u^\mu = -1 \). We then find the only non-zero component of the energy transfer four-vector on large scales to be
\[ Q_{0(\alpha)} = -Q_{0\alpha} \left(1 + \phi_1 + \frac{1}{2}\phi_2 - \frac{1}{4}\phi_1^2\right) - \delta Q_{1\alpha} (1 + \phi_1) - \delta Q_{2\alpha}, \]  \hspace{1cm} (2.10)
where \( Q_{0\alpha}, \delta Q_{1\alpha} \) and \( \delta Q_{2\alpha} \) are the energy transfer to the \( \alpha \)-fluid in the background and at first and at second order, respectively.

2.1. Background

Energy conservation for the \( \alpha \)-fluid in the background is given from equation (2.4) as
\[ \dot{\rho}_{0\alpha} = -3H (\rho_{0\alpha} + P_{0\alpha}) + Q_{0\alpha}, \]  \hspace{1cm} (2.11)
where \( H = \dot{a}/a \) is the Hubble parameter, and \( \rho_{0\alpha} \) and \( P_{0\alpha} \) are the energy density and the pressure, respectively, of the \( \alpha \)-fluid. Total energy conservation is then given by summing over the individual fluids and using equation (2.5) as
\[ \dot{\rho}_0 = -3H (\rho_0 + P_0), \]  \hspace{1cm} (2.12)
where \( \rho_0 = \sum_\alpha \rho_{0\alpha} \).

The Friedmann constraint is given from the 0 – 0 component equation (2.1) as
\[ H^2 = \frac{8\pi G}{3} \rho_0. \]  \hspace{1cm} (2.13)
2.2. First order perturbations

We now give the governing equations on large scales at first order in the perturbations in the flat gauge, denoting quantities evaluated in this gauge by a ‘tilde’. The governing equations in an arbitrary gauge are given in appendix A.1.1.

The energy conservation equation for the $\alpha$-fluid at first order is given from equation (2.4) on large scales as

$$\dot{\tilde{\delta\rho}}_{1\alpha} + 3H (\tilde{\delta\rho}_{1\alpha} + \tilde{\delta P}_{1\alpha}) - Q_{0\alpha}\tilde{\phi}_{1} - \tilde{\delta Q}_{1\alpha} = 0.$$  (2.14)

The total energy density perturbation is related to the individual fluid densities, and similarly for the pressure perturbations, by

$$\tilde{\delta\rho}_{1} \equiv \sum_{\alpha} \tilde{\delta\rho}_{1\alpha}, \quad \tilde{\delta P}_{1} \equiv \sum_{\alpha} \tilde{\delta P}_{1\alpha}$$  (2.15)

and we get, using the constraint equation (2.5), from equation (2.14) the evolution equation for the total energy density perturbation

$$\dot{\tilde{\delta\rho}}_{1} + 3H (\tilde{\delta\rho}_{1} + \tilde{\delta P}_{1}) = 0.$$  (2.16)

The $0-0$ Einstein equation on flat slices is, using equation (2.1) and the background Friedmann constraint (2.13), given by

$$\tilde{\phi}_{1} = -\frac{1}{2} \tilde{\delta\rho}_{1} \rho_{0}.$$  (2.17)

The curvature perturbation on uniform $\alpha$ fluid energy density hyper-surfaces at first order is given by [42]

$$\zeta_{1\alpha} = -H \frac{\delta\rho_{1\alpha}}{\rho_{0\alpha}}.$$  (2.18)

The curvature perturbation on uniform total energy density hyper-surfaces at first order is given by

$$\zeta_{1} = -H \frac{\tilde{\delta\rho}_{1}}{\rho_{0}}$$  (2.19)

and related to the curvature perturbation on uniform $\alpha$ fluid slices by

$$\zeta_{1} = \sum_{\alpha} \frac{\rho_{0\alpha}}{\rho_{0}} \zeta_{1\alpha}.$$  (2.20)

As in the background we introduce new variables, the normalized energy densities at first order,

$$\delta\Omega_{1\alpha} \equiv \frac{\tilde{\delta\rho}_{1\alpha}}{\rho_{0}},$$  (2.21)

which allow us in combination with choosing the number of e-foldings as a time variable to write the governing equations in the following sections in a particularly compact form.

In terms of the new variables the curvature perturbation on uniform $\alpha$ fluid energy density hyper-surfaces, given in equation (2.18), is simply

$$\zeta_{1\alpha} = -H \frac{\rho_{0}}{\rho_{0\alpha}} \delta\Omega_{1\alpha}.$$  (2.22)
2.3. Second order

We now give the governing equations on large scales at second order in the perturbations in the flat gauge, denoting quantities evaluated in this gauge by a ‘tilde’. The governing equations in an arbitrary gauge are given in appendix A.1.2.

The energy conservation equation for the $\alpha$-fluid at second order is given from equation (2.4) on large scales by

$$\dot{\tilde{\delta}\rho_{2\alpha}} + 3H (\tilde{\delta}\rho_{2\alpha} + \tilde{\delta}P_{2\alpha}) - Q_{0\alpha} (\tilde{\phi}_2 - \tilde{\phi}_1^2) - \tilde{\delta}Q_{2\alpha} - 2\phi_1 \delta \tilde{Q}_{1\alpha} = 0. \quad (2.23)$$

Using equation (2.5), the evolution equation for the total energy density is

$$\dot{\tilde{\delta}\rho_2} + 3H (\tilde{\delta}\rho_2 + \tilde{\delta}P_2) = 0, \quad (2.24)$$

where the total density and pressure perturbations are given in terms of the individual fluid ones by

$$\tilde{\delta}\rho_{2\alpha} = \sum_{\alpha} \tilde{\delta}\rho_{2\alpha}, \quad \tilde{\delta}P_{2\alpha} = \sum_{\alpha} \tilde{\delta}P_{2\alpha}. \quad (2.25)$$

The 0–0 Einstein equation on flat slices is, using equation (2.1) and the background Friedmann constraint (2.13), given by

$$\tilde{\phi}_2 - 4\tilde{\phi}_1^2 = -\frac{1}{2} \frac{\dot{\tilde{\delta}\rho}_2}{\tilde{\rho}_0}. \quad (2.26)$$

The curvature perturbation at second order in terms of uniform $\alpha$-density perturbations on flat slices is given by [23, 33]

$$\zeta_{2\alpha} = -\frac{H}{\tilde{\rho}_{0\alpha}} \tilde{\delta}\rho_{2\alpha} + 2 \frac{H}{\tilde{\rho}_{0\alpha}} \tilde{\delta}\rho_{1\alpha} \tilde{\rho}_{1\alpha} + \frac{H}{\tilde{\rho}_{0\alpha}} \left[ H (5 + 3c_{s\alpha}^2) + \frac{\dot{H}}{H} \frac{Q_{0\alpha}}{\tilde{\rho}_{0\alpha}} - \frac{\dot{Q}_{0\alpha}}{\tilde{\rho}_{0\alpha}} \right] \tilde{\delta}\rho_{1\alpha}^2, \quad (2.27)$$

where $c_{s\alpha}^2 \equiv \tilde{P}_{0\alpha}/\tilde{\rho}_{0\alpha}$ is the adiabatic sound speed of the $\alpha$-fluid.

The curvature perturbation at second order in terms of the total density perturbations on flat slices is given by [23]

$$\zeta_2 = -\frac{H}{\tilde{\rho}_0} \tilde{\delta}\rho_2 + 2 \frac{H}{\tilde{\rho}_0} \tilde{\delta}\rho_1 \tilde{\rho}_1 + \frac{H^2}{\tilde{\rho}_0} (5 + 3c_2^2) \tilde{\delta}\rho_1^2, \quad (2.28)$$

where $c_2^2 \equiv \tilde{P}_0/\tilde{\rho}_0$ is the total adiabatic sound speed related to the individual speeds $c_{\alpha}^2$ by

$$c_2^2 = \sum_{\alpha} \frac{\tilde{\rho}_{0\alpha}}{\tilde{\rho}_0} c_{\alpha}^2. \quad (2.29)$$

As at first order we introduce new variables, the normalized energy densities, at second order, allowing us to rewrite the governing equations in the following sections in a particularly compact form,

$$\delta\Omega_{2\alpha} \equiv \frac{\tilde{\delta}\rho_{2\alpha}}{\tilde{\rho}_0}. \quad (2.30)$$

The curvature perturbation $\zeta_2$, defined above in equation (2.28), is related to the curvature perturbation employed in the $\Delta N$ formalism (see also [43]), which we denote
by $\zeta_{\text{SB}}$, by [28, 37]
\[ \zeta_{\text{SB}} = \zeta - 2\zeta_1^2. \quad (2.31) \]

It was originally introduced by Salopek and Bond [34] and employed by Maldacena in studies of non-Gaussianity in [15].

3. The model

In this section we specify the curvaton model and apply the governing equations given in the previous section order by order. We model the curvaton as a pressureless fluid [3], and hence our system will be governed by the equations of state
\[ P_\sigma = 0, \quad P_\gamma = \frac{1}{3} \rho_\gamma, \quad (3.1) \]
where the subscripts ‘$\sigma$’ and ‘$\gamma$’ denote the curvaton and the radiation fluid, respectively. The decay of the curvaton is described by a fixed decay rate, $\Gamma = \text{const}$,
\[ Q_\sigma = -\Gamma \rho_\sigma, \quad Q_\gamma = \Gamma \rho_\sigma, \quad (3.2) \]
where we used equation (2.5).

3.1. Background

The background evolution equations are from equation (2.11) and using equations (3.1) and (3.2) given by
\[ \dot{\rho}_\sigma = -3H \rho_0\sigma - \Gamma \rho_0\sigma, \quad (3.3) \]
\[ \dot{\rho}_\gamma = -4H \rho_0\gamma + \Gamma \rho_0\sigma. \quad (3.4) \]

We now change to a new set of variables. First we introduce normalized energy densities in the background,
\[ \Omega_{0\alpha} \equiv \frac{\rho_{0\alpha}}{\rho_0}, \quad (3.5) \]
and define the reduced decay rate as
\[ g \equiv \frac{\Gamma}{\Gamma + H}. \quad (3.6) \]

We change the time coordinate from coordinate time $t$ to the number of e-foldings $N \equiv \ln a$, that is $\frac{d}{dt} = H \frac{d}{dN}$. The normalized radiation energy density is then simply given from the Friedmann equation, (2.13), as $\Omega_{0\gamma} \equiv 1 - \Omega_{0\sigma}$, and we get the system of background evolution equations in terms of these new variables
\[ \Omega'_{0\sigma} = \Omega_{0\sigma} \left( 1 - \Omega_{0\sigma} - \frac{g}{1 - g} \right), \quad (3.7) \]
\[ g' = \frac{1}{2} (4 - \Omega_{0\sigma}) (1 - g) g. \quad (3.8) \]

Solutions for the system (3.7) and (3.8) are given in figure 1 for two different initial conditions, $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$ and $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-6}$. 

Journal of Cosmology and Astroparticle Physics 09 (2006) 008 (stacks.iop.org/JCAP/2006/i=09/a=008) 7
A numerical study of non-Gaussianity in the curvaton scenario

Figure 1. Evolution of the normalized background curvaton density, $\Omega_{0\sigma}$, and the normalized decay rate, $g$, as a function of the number of e-foldings, starting with initial density and decay rate $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$, corresponding to $p_{\text{in}} = 0.32$ on the left panel, and on the right panel with $\Gamma/H = 10^{-6}$, corresponding to $p_{\text{in}} = 10$.

It was shown in [7] that the solutions of the system (3.7) and (3.8) depend only on a single parameter since we can write $\Omega_{0\sigma} = \Omega_{0\sigma}(g)$, and for $g \ll 1$ we can solve the system explicitly, which gives $\Omega_{0\sigma} \propto \sqrt{g}$. We therefore define the parameter [7,9]

$$p_{\text{in}} \equiv \frac{\Omega_{0\sigma}}{\sqrt{g}}|_{\text{in}},$$

the subscript ‘in’ denoting the initial conditions. For the initial conditions $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$ and $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-6}$ the parameter $p_{\text{in}}$ takes the values 0.32 and 10, respectively.

### 3.2. First order

The perturbed energy transfer rates are given from equation (3.2) at first order as

$$\delta Q_{1\sigma} = -\Gamma \delta \rho_{1\sigma}, \quad \delta Q_{1\gamma} = \Gamma \delta \rho_{1\gamma}. \tag{3.10}$$

The evolution equations at first order are from equation (2.14) and equations (3.1), and using (3.10) in terms of the normalized energy densities defined in equation (2.21), given by

$$\delta \Omega_{1\sigma}^\prime + \left[\frac{3 - 2g}{1 - g} - \frac{\Omega_{0\sigma}}{2} \frac{6 - 5g}{1 - g} - 4\Omega_{0\gamma}\right] \delta \Omega_{1\sigma} - \frac{\Omega_{0\sigma}}{2} \frac{g}{1 - g} \delta \Omega_{1\gamma} = 0, \tag{3.11}$$

$$\delta \Omega_{1\gamma}^\prime + \left[4 \left(1 - \Omega_{0\gamma}\right) - \frac{6 - 7g \Omega_{0\sigma}}{1 - g} \frac{\Omega_{0\sigma}}{2}\right] \delta \Omega_{1\gamma} - \frac{g}{1 - g} \left(1 - \frac{\Omega_{0\sigma}}{2}\right) \delta \Omega_{1\sigma} = 0. \tag{3.12}$$

The curvature perturbations at first order on uniform curvaton and radiation density hypersurfaces are from equation (2.18) given by

$$\zeta_{1\sigma} = \frac{1 - g}{(3 - 2g) \Omega_{0\sigma}} \delta \Omega_{1\sigma}, \tag{3.13}$$

$$\zeta_{1\gamma} = \frac{1 - g}{4 \left(1 - g\right) \Omega_{0\gamma} - g \Omega_{0\sigma}} \delta \Omega_{1\gamma}. \tag{3.14}$$
A numerical study of non-Gaussianity in the curvaton scenario

Figure 2. Evolution of the total curvature perturbation, $\zeta_1$, and the normalized density perturbations at first order as a function of the number of e-foldings, starting with $\zeta_{1\sigma} = 1$ and initial density and decay rate $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$, corresponding to $p_{in} = 0.32$.

Figure 3. Same as figure 2 but with $\Gamma/H = 10^{-6}$ initially, corresponding to $p_{in} = 10$.

The curvature perturbation on uniform total density slices in terms of the new variables is given by

\[
\zeta_1 = \frac{\delta \Omega_{1\sigma} + \delta \Omega_{1\gamma}}{3\Omega_{0\sigma} + 4\Omega_{0\gamma}}. \tag{3.15}
\]

Solutions for the equation system (3.11) and (3.12) are given in figures 2 and 3 for two different sets of initial conditions, $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$ and $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-6}$, corresponding to $p_{in} = 0.32$ and $p_{in} = 10$, respectively. Using equation (3.15) we also plot the evolution of $\zeta_1$. For the perturbations we use the initial conditions

\[
\zeta_{1\sigma, in} = 1, \quad \zeta_{1\gamma, in} = 0, \tag{3.16}
\]

which can be easily translated into initial conditions for $\delta \Omega_{1\sigma}$ using equation (3.13), and facilitates comparison with reference [7].
Note that the values for $\delta \Omega_{1\sigma}$ and $\delta \Omega_{1\gamma}$ can exceed unity, as can be seen in figure 3. This does not indicate the ‘breakdown of perturbation theory’ or anything dramatic like it, but is merely an artifact of normalizing the density perturbations by the total background density $\rho_0$, which can itself be small. As in the background, the normalized energy densities together with the choice of time coordinate give a particularly neat system of governing equations.

### 3.3. Second order

The perturbed energy transfer rates are given from equation (3.2) at second order as

$$
\delta Q_{2\sigma} = -\Gamma \delta \rho_{2\sigma}, \quad \delta Q_{2\gamma} = \Gamma \delta \rho_{2\sigma}.
$$

We then find evolution equations at second order from equation (2.23) and using equations (3.1) and (3.17) in terms of the normalized energy densities defined above in equations (2.21) and (2.30) to be

$$
\delta \Omega_{2\sigma} + \left[ \frac{3 - 2 g}{1 - g} - \frac{\Omega_{0\sigma} 6 - 5 g}{2 (1 - g)} - 4 \Omega_{0\gamma} \right] \delta \Omega_{2\sigma} - \frac{\Omega_{0\sigma}}{2 (1 - g)} \delta \Omega_{2\gamma},
$$

$$
\delta \Omega_{2\gamma} + \left[ 4 (1 - \Omega_{0\gamma}) - \frac{6 - 7 g \Omega_{0\sigma}}{2} \right] \delta \Omega_{2\gamma} - \left( 1 - \frac{\Omega_{0\sigma}}{2} \right) \frac{g}{1 - g} \delta \Omega_{2\sigma},
$$

with

$$
\delta \Omega_{2\sigma} + \delta \Omega_{2\gamma} + \left[ \frac{3 - 2 g}{1 - g} - \frac{\Omega_{0\sigma} 6 - 5 g}{2 (1 - g)} - 4 \Omega_{0\gamma} \right] \delta \Omega_{2\sigma} - \frac{\Omega_{0\sigma}}{2 (1 - g)} \delta \Omega_{2\gamma} = 0,
$$

$$
\delta \Omega_{2\gamma} + \left[ 4 (1 - \Omega_{0\gamma}) - \frac{6 - 7 g \Omega_{0\sigma}}{2} \right] \delta \Omega_{2\gamma} - \left( 1 - \frac{\Omega_{0\sigma}}{2} \right) \frac{g}{1 - g} \delta \Omega_{2\sigma} = 0.
$$

The adiabatic sound speed in a multi-fluid system is given above in equation (2.29) and we find for the two-fluid curvaton model

$$
c_{s}^2 = \frac{1}{3} \left( \frac{1 - g}{1 - g} \right) \frac{\Omega_{0\gamma} - g \Omega_{0\sigma}}{\Omega_{0\sigma} + 4 \Omega_{0\gamma}}.
$$

The curvature perturbation on uniform total density hypersurfaces at second order in terms of the normalized quantities is

$$
\zeta_2 = \frac{\delta \Omega_{2\sigma} + \delta \Omega_{2\gamma}}{3 \Omega_{0\sigma} + 4 \Omega_{0\gamma}} - \left( 1 - 3 c_s^2 \right) \left( \frac{\delta \Omega_{1\sigma} + \delta \Omega_{1\gamma}}{3 \Omega_{0\sigma} + 4 \Omega_{0\gamma}} \right)^2 - \frac{2 \left( \delta \Omega_{1\sigma} + \delta \Omega_{1\gamma} \right) \delta \Omega_{1\gamma}}{(3 \Omega_{0\sigma} + 4 \Omega_{0\gamma})^2}.
$$

where $c_s^2$ is given above in equation (3.20).

The system of equations (3.18) and (3.19) is readily integrated using a standard fourth order Runge–Kutta solver [44]. We give the solutions for this system of equations for the two different sets of initial conditions, $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$ and $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-6}$, corresponding to $p_{in} = 0.32$ and $p_{in} = 10$, in figures 4 and 5. Using equation (3.21) we also plot the evolution of $\zeta_2$. The initial conditions for the second order perturbations are chosen as

$$
\delta \Omega_{2\sigma, in} = 0, \quad \delta \Omega_{2\gamma, in} = 0.
$$

Note that the values for $\delta \Omega_{2\sigma}$ and $\delta \Omega_{2\gamma}$ can exceed unity, as can be seen in figure 5. As at first order, this is merely an artifact of using normalized energy densities. We do however...
A numerical study of non-Gaussianity in the curvaton scenario

Figure 4. Evolution of the total curvature perturbation, $\zeta_2$, and the normalized density perturbations at second order as a function of the number of e-foldings, with initially $\zeta_{1,\sigma,\text{in}} = 1$ and density and decay rate $\Omega_{0\sigma} = 10^{-2}$ and $\Gamma/H = 10^{-3}$, corresponding to $p_{\text{in}} = 0.32$.

Figure 5. Same as figure 4 but with $\Gamma/H = 10^{-6}$ initially, corresponding to $p_{\text{in}} = 10$.

see a new effect: at second order the energy densities $\delta \rho_{2\alpha}$ can and do become negative, as can be seen clearly in figures 4 and 5. This is a ‘real’ effect and not a normalization artifact since $\rho_0 \geq 0$ always. However, the total energy density $\rho$ as given by summing over all the terms in the power series expansion equation (2.6) again stays positive definite.

4. Relating the perturbative treatment to the $\Delta N$ formalism

The $\Delta N$ formalism [35] provides a simple tool to calculate the curvature perturbation on large scales at all orders in the perturbations on scales larger than the horizon [36]–[38]. The main simplification compared to cosmological perturbation theory stems from the fact that we only need the background evolution equations, and not the full governing equations at all orders of interest. However, if there is no analytic solution, the numerics necessary to get a result turn out to be quite involved as can be seen below. Nevertheless, we shall outline the calculation in the following.
A numerical study of non-Gaussianity in the curvaton scenario

The $\Delta N$ formalism relates the curvature perturbation on uniform density hypersurfaces to the perturbation in the number of e-foldings from the uniform density to the flat slicing,

$$\zeta = \delta N.$$  \hfill (4.1)

To get the number of e-foldings $N$ we use equation (3.8) to get $dN$ in terms of $dg$, and integrate,

$$N = 2 \int_{g_{in}}^{g_{fin}} \frac{dg}{g (1 - g)(4 - \Omega_{0\sigma})}.$$  \hfill (4.2)

The curvature perturbation in the $\Delta N$ formalism is then given from equation (4.1) by expanding $N$ in a Taylor series, which leads in the curvaton case to \cite{12,38}

$$\zeta = \frac{\partial N}{\partial \Omega_{0\sigma \iota}} \delta \Omega_{\sigma \iota} + \frac{1}{2} \frac{\partial^2 N}{\partial \Omega_{0\sigma \iota}^2} \delta \Omega_{\sigma \iota}^2,$$  \hfill (4.3)

where the partial differentials are

$$\frac{\partial N}{\partial \Omega_{0\sigma \iota}} = 2 \int_{g_{in}}^{g} \frac{dg}{g (1 - g)(4 - \Omega_{0\sigma})} \frac{\partial \Omega_{0\sigma}}{\partial \Omega_{0\sigma}};$$  \hfill (4.4)

$$\frac{\partial^2 N}{\partial \Omega_{0\sigma \iota}^2} = 2 \int_{g_{in}}^{g} \frac{dg}{g (1 - g)(4 - \Omega_{0\sigma})} \left[ \frac{\partial^2 \Omega_{0\sigma}}{\partial \Omega_{0\sigma}^2} + \frac{2}{(4 - \Omega_{0\sigma})} \left( \frac{\partial \Omega_{0\sigma}}{\partial \Omega_{0\sigma}} \right)^2 \right].$$  \hfill (4.5)

Note that to make contact with first and second order perturbation theory $\zeta$ and $\delta \Omega_{\sigma \iota}$ have to be expanded up to second order, where in this case the second order curvature perturbation corresponds to $\zeta_{2SB}$, defined above in equation (2.31), related to $\zeta_2$ as specified in equation (2.28).

Although in principle we can evaluate the integrals in equations (4.4) and (4.5) numerically and then differentiate them with respect to the initial conditions to get the value of $\zeta$, this is (arguably) more difficult than solving a set of coupled differential equations. We therefore do not use the $\Delta N$ formalism in the following sections, and solve instead the system of differential equations presented in section 3.

However, the $\Delta N$ formalism is used in \cite{45} in another numerical study of the curvaton scenario. The results are similar to the ones presented in this paper, but the computing time required in the $\Delta N$ case is increased by factor of roughly $\sim 100$ compared to solving the system of differential equations presented in section 3.

5. The non-linearity parameter $f_{NL}$: results and discussion

In this section we give the non-linearity parameter $f_{NL}$ calculated numerically using the governing equations at second order of sections 2 and 3 and compare it to previous numerical first order results and analytical sudden decay estimates.

The non-Gaussianity parameter $f_{NL}$ is defined as \cite{38,46}

$$\zeta = \zeta_{g} + \frac{3}{5} f_{NL} \left( \zeta_{g}^2 - \bar{\zeta}_{g}^2 \right),$$  \hfill (5.1)

where $\zeta$ is the curvature perturbation at all orders, $\zeta_{g}$ the Gaussian part of $\zeta$, and the ‘bar’ denotes the spatial average. There has been some confusion in the literature as to the
A numerical study of non-Gaussianity in the curvaton scenario

sign of $f_{NL}$, which becomes relevant if the result is compared with observations. The sign convention chosen here coincides with the one used originally by Komatsu and Spergel [46] and adopted by most observational studies, and corrects the sign error introduced in [6] and carried through in much subsequent work [20, 24].

We now relate the curvaton field fluctuations to the curvaton fluid energy density. The energy density in the curvaton field can be approximated by

$$\rho_\sigma = \frac{1}{2} m^2 \sigma^2$$

where $m$ is the curvaton mass and $\sigma$ is the amplitude of the curvaton field. Expanding the curvaton amplitude to first order, $\sigma = \sigma_0 + \delta \sigma_1$, we get from equation (5.2)

$$\rho_{0\sigma} = \frac{1}{2} m^2 \sigma_0^2,$$

$$\frac{\delta \rho_{1\sigma}}{\rho_{0\sigma}} \equiv 2 \frac{\delta \sigma_1}{\sigma_0} + \left( \frac{\delta \sigma_1}{\sigma_0} \right)^2,$$

$$\frac{\delta \rho_{2\sigma}}{\rho_{0\sigma}} \equiv 0.$$ (5.5)

Note that including the quadratic term $(\delta \sigma_1/\sigma_0)^2$ in the first order energy density and setting the second order energy density perturbation to zero is just convention, following reference [6]. In [20] this term is included in the second order energy density perturbation of the curvaton fluid. This choice does not affect the final results.

5.1. Sudden decay

In the sudden decay one assumes that the curvaton does not decay into radiation until a time $t_{\text{dec}}$, when all of the curvaton energy density decays suddenly; the normalized energy density of the curvaton at decay is denoted $\Omega_{\sigma_{\text{dec}}}$. The sudden decay approximation has been widely used in the literature to study the curvaton scenario without having to resort to numerical calculations; see, e.g., [3, 6, 20, 38]. In order to be able to compare the sudden decay approximation to the numerical calculation we now give a prescription to calculate $\Omega_{\sigma_{\text{dec}}}$.

The normalized background energy density can be approximated by [3, 11, 12]

$$\Omega_{0\sigma} = \frac{\sigma_0^2}{\sigma_0^2 + 6 M_{\text{pl}}^2 \sqrt{H/m}},$$

where $M_{\text{pl}}^2 = (8 \pi G)^{-1}$. Assuming that the evolution of the background curvaton amplitude from the initial time up to curvaton decay is negligible and using that initially $H_{\text{in}} = m$, and at curvaton decay $H_{\text{dec}} = \Gamma$ we can use equation (5.6) to relate the parameter $p_{\text{in}}$, defined in equation (3.9), to the background energy density of the curvaton at decay. We therefore define

$$\Omega_{\sigma_{\text{dec}}} \equiv \frac{p_{\text{in}}}{1 + p_{\text{in}}}.$$ (5.7)

Note that equation (36) of [6], corresponding to equations (5.8) and (5.12) here, has the correct sign for $f_{NL}$; however, there is a sign error in the derivation in [6].
as the energy density of the curvaton in the sudden decay approximation. The agreement $\Omega_{\sigma_{\text{dec}}}$ defined in equation (5.7) with $\Omega_{\sigma_{\text{dec}}}$ used in [7] is quite good, and we use the definition (5.7) in the following to compare our numerical results with the sudden decay approximation.

We now briefly review the results of previous analytical treatments using the sudden decay approximation to calculate the non-linearity parameter $f_{\text{NL}}$ in the curvaton scenario.

The non-linearity parameter in the sudden decay approximation using first order perturbation theory, however, using the definition of the first order energy density perturbation quadratic in the curvaton fluctuations equation (5.4), is [3, 6]

$$f_{\text{NL}} = \frac{5}{4\Omega_{\sigma_{\text{dec}}}}. \quad (5.8)$$

Using second order perturbation theory the non-linearity parameter in the sudden decay approximation was found to be [20, 28]

$$f_{\text{NL}} = \frac{5}{4\Omega_{\sigma_{\text{dec}}}} - \frac{5}{6}\Omega_{\sigma_{\text{dec}}} - \frac{5}{3}. \quad (5.9)$$

5.2. Numerical solutions

The transfer parameter at first order relating the initial curvature perturbation on uniform curvaton density hypersurfaces to the final value of the total curvature perturbation is defined as [3, 6, 7]

$$r_1 \equiv \frac{\zeta_{1,\text{fin}}}{\zeta_{1,\sigma,\text{in}}}. \quad (5.10)$$

We define the transfer parameter at second order

$$r_2 \equiv \frac{\zeta_{2,\text{fin}}}{\zeta_{2,1,\sigma,\text{in}}}, \quad (5.11)$$

relating the final value of the total curvature perturbation to the initial curvature perturbation on uniform curvaton slices. The values for $r_1$ and $r_2$ coincide for our choice of initial condition, $\zeta_{1,\sigma,\text{in}} = 1$, with the final values of the curvature perturbations at first and second order, $\zeta_{1,\text{fin}}$ and $\zeta_{2,\text{fin}}$, and are given in figure 6 versus $\Omega_{\sigma_{\text{dec}}}$ and $p_{\text{in}}$.

The non-linearity parameter using first order perturbation theory is given in terms of the transfer parameter defined in equation (5.10) as [6, 7]

$$f_{\text{NL}} = \frac{5}{4r_1}. \quad (5.12)$$

Using second order perturbation theory we find the non-linearity parameter $f_{\text{NL}}$ from equation (5.1), expanding $\zeta$ to second order, and get in terms of the transfer parameters at first and second order

$$f_{\text{NL}} = \frac{5}{4r_1} + \frac{5}{6} \frac{r_2}{r_1^2} - \frac{5}{3}. \quad (5.13)$$

In the above calculations we identified $\zeta_{g}$ with the part of $\zeta_{1}$ linear in the curvaton field fluctuation, i.e., the first term in equation (5.4).
Figure 6. The final values of the normalized curvature perturbations at first and second order, $\zeta_{1,\text{in}}$ and $\zeta_{2,\text{in}}$, for an initial value $\zeta_{1,\text{in}} = 1$, versus the background curvaton energy density at decay, $\Omega_{\sigma_{\text{dec}}}$, in the left panel and versus $p_{\text{in}}$ in the right panel.

We can finally relate the transfer parameters $r_1$ and $r_2$ to the total curvature perturbation, $\zeta = \zeta_1 + \frac{1}{2}\zeta_2$, evaluated after the curvaton has decayed,

$$\zeta_{\text{fin}} = r_1 \zeta_{1,\text{in}} + \frac{1}{2} r_2 \zeta_{1,\text{in}}^2.$$  \hfill (5.14)

Using the definition of the curvature perturbation on uniform curvaton density hypersurfaces, equation (2.18), and the expression for the curvaton energy density in terms of the curvaton amplitude, equation (5.4), we get

$$\zeta = \frac{2}{3} r_1 \frac{\delta \sigma_1}{\sigma_0} + \frac{1}{3} \left( r_1 + \frac{2}{3} r_2 \right) \left( \frac{\delta \sigma_1}{\sigma_0} \right)^2.$$  \hfill (5.15)

We can compare these results to the expression found using the $\Delta N$-formalism, expressed in terms of the curvaton perturbation (instead of the normalized energy perturbation used in section 4) [12, 38],

$$\zeta_{\text{SB}} = N_{\sigma} \delta \sigma + \frac{1}{2} N_{\sigma \sigma} \delta \sigma^2.$$  \hfill (5.16)

The curvature perturbation employed in the $\Delta N$-formalism, $\zeta_{\text{SB}}$, is related to $\zeta$ by equation (2.31), and we get

$$\zeta_{\text{SB}} = \frac{2}{3} r_1 \frac{\delta \sigma_1}{\sigma_0} + \frac{1}{3} \left( r_1 + \frac{2}{3} r_2 - \frac{4}{3} r_1^2 \left( \frac{\delta \sigma_1}{\sigma_0} \right)^2 \right).$$  \hfill (5.17)

and therefore

$$N_{\sigma} = \frac{2}{3} r_1, \quad N_{\sigma \sigma} = \frac{2}{3} \sigma_0^2 \left( r_1 + \frac{2}{3} r_2 - \frac{4}{3} r_1^2 \right).$$  \hfill (5.18)

5.3. Curvaton amplitude evolution

So far we have assumed that the curvaton field does not evolve between the end of inflation and curvaton decay. In order to allow for the evolution of curvaton field amplitude $\sigma$ we assume that it depends on the initial value set during inflation $\sigma_e$ by $\sigma = \sigma(\sigma_e)$ which gives for the curvaton field fluctuation [8, 10, 12]

$$\delta \sigma = \sigma' \delta \sigma_e + \frac{1}{2} \sigma'' \delta \sigma^2_e.$$  \hfill (5.19)
where $\sigma' \equiv \partial \sigma / \partial \sigma_e$. For the first order energy density we then find (including again the quadratic term)

$$\frac{\delta \rho_{1\sigma}}{\rho_{0\sigma}} = 2 \frac{\delta \sigma_e}{\sigma_0} \sigma_0' + \left( \frac{\delta \sigma_e}{\sigma_0} \right)^2 \left( 1 + \sigma_0 \frac{\sigma''_0}{\sigma'_0^2} \right) \sigma'_0^2. \tag{5.20}$$

We therefore get for the non-linearity parameter

$$f_{NL} = \left[ \frac{5}{4r_1} + \frac{5}{6} \frac{r_2}{r_1^2} \right] \left( 1 + \sigma_0 \frac{\sigma''_0}{\sigma'_0^2} \right) - \frac{5}{3}, \tag{5.21}$$

instead of equation (5.13) above. However, in order to calculate a numerical value for $f_{NL}$ we now have to calculate the evolution of $\sigma$ in detail and specify a curvaton model. We shall therefore not pursue this issue further and refer to [10], where this issue was studied in detail.

### 5.4. Results and discussion

Our results are summed up in figures 7–9: in figures 7 and 8 we plot the non-linearity parameter calculated numerically using equation (5.12) at first order and equation (5.13) at second order.
A numerical study of non-Gaussianity in the curvaton scenario

Figure 9. The difference of the numerical and the sudden decay approximation value of the non-linearity parameter, $\Delta f_{NL}$, versus $\Omega_{\sigma_{\text{dec}}}$ and $p_{\text{in}}$.

at second order for two different parametrizations, namely $\Omega_{\sigma_{\text{dec}}}$ and $p_{\text{in}}$. In the same figures we also plot the non-linearity parameter $f_{NL}$ in the sudden decay approximation at first and second orders from equations (5.8) and (5.9), respectively. We truncated the graphs at $f_{NL} = 120$ in accordance with the current observational bounds (see below). We first note how well the sudden decay approximation and the numerical solution at first and second orders agree. However, at first order we find that $f_{NL} = 5/4$ for $\Omega_{\sigma_{\text{dec}}} = 1$ or large values of $p_{\text{in}}$, whereas including the second order effects we get $f_{NL} = -5/4$ for $\Omega_{\sigma_{\text{dec}}} = 1$ or large values of $p_{\text{in}}$.

In figure 9 we plot the difference between the non-linearity parameter obtained numerically and using the sudden decay approximation, both at second order,

$$\Delta f_{NL} \equiv f_{NL} \bigg|_{\text{numerical}} - f_{NL} \bigg|_{\text{sudden decay}}. \quad (5.22)$$

We now see more clearly the excellent agreement of the sudden decay approximation for large parameters $p_{\text{in}}$ and $\Omega_{\sigma_{\text{dec}}}$. However, for small $p_{\text{in}}$ and $\Omega_{\sigma_{\text{dec}}}$ the sudden decay approximation works less well, deviating from the numerical solution by up to 10%.

We finally give the observational constraint on the non-linearity parameter $f_{NL}$ from the recently published WMAP three-year data. Spergel et al found [47]: $-54 < f_{NL} < 114$ (at 95% confidence level). The curvaton model is therefore well within the current observational bounds. However, if future observations give a large negative value for the non-linearity parameter, the curvaton model would be ruled out, at least without strong evolution of the curvaton amplitude from the beginning of the oscillations to curvaton decay, as pointed out in section 5.3 above.

Acknowledgments

The authors are grateful to Jussi Valiviita and David Wands for useful comments. Algebraic computations of tensor components were performed using the GRTensorII package for Maple.
Appendix. Governing equations

Here we first give the governing equations on large scales in the general case without gauge restrictions and then the equations given in section 3 in terms of non-normalized energy densities.

A.1. Governing equations without gauge restriction

In this subsection we give the governing equations on large scales in the general case without any gauge restrictions, i.e. without choosing a particular hypersurface.

A.1.1. First order. Energy conservation of the $\alpha$-fluid is given from equation (2.4) at first order as

$$\delta \dot{\rho}_{1\alpha} + 3H (\delta \rho_{1\alpha} + \delta P_{1\alpha}) - 3\dot{\psi}_1 (\rho_{0\alpha} + P_{0\alpha}) - Q_{0\alpha} \phi_1 - \delta Q_{1\alpha} = 0. \tag{A.1}$$

Total energy conservation follows from equation (A.1) above, and using equations (2.5) and (2.15) is given by

$$\delta \dot{\rho}_1 + 3H (\delta \rho_1 + \delta P_1) - 3\dot{\psi}_1 (\rho_0 + P_0) = 0. \tag{A.2}$$

The $0-0$ Einstein equation is given from equation (2.1) as

$$3H (\dot{H} \phi_1 + \dot{\psi}_1) = -4\pi G \delta \rho_1. \tag{A.3}$$

A.1.2. Second order. Energy conservation of the $\alpha$-fluid is given from equation (2.4) at second order as

$$\delta \dot{\rho}_{2\alpha} + 3H (\delta \rho_{2\alpha} + \delta P_{2\alpha}) - 3\dot{\psi}_2 (\rho_{0\alpha} + P_{0\alpha}) - 6 (\delta \rho_{1\alpha} + \delta P_{1\alpha}) \dot{\psi}_1 - 12 (\rho_{0\alpha} + P_{0\alpha}) \dot{\psi}_1 \psi_1 - Q_{0\alpha} (\phi_2 - \phi_1^2) - 2\phi_1 \delta Q_{1\alpha} - \delta Q_{2\alpha} = 0. \tag{A.4}$$

Following a similar route as at first order, the conservation of the total energy density is given at second order by

$$\delta \dot{\rho}_2 + 3H (\delta \rho_2 + \delta P_2) - 3\dot{\psi}_2 (\rho_0 + P_0) - 6 (\delta \rho_1 + \delta P_1) \dot{\psi}_1 - 12 (\rho_0 + P_0) \dot{\psi}_1 \psi_1 = 0 \tag{A.5}$$

and the $0-0$ Einstein equation is given by

$$3H^2 (\phi_2 - 4\phi_1^2) + 3 \left( H \dot{\psi}_2 - \dot{\psi}_1^2 \right) + 12H \dot{\psi}_1 (\psi_1 - \phi_1) = -4\pi G \delta \rho_2. \tag{A.6}$$

A.2. Governing equations in terms of non-normalized energy densities

In this subsection we give the governing equations presented in sections 3.2 and 3.3 above in terms of the normalized quantities in terms of the non-normalized energy densities and decay rate. We use the number of e-foldings $N$ as time coordinate and work throughout in the flat gauge (omitting the ‘tilde’).
We get, at first order,
\[ \delta \rho'_{1\sigma} + \left( 3 + \frac{\Gamma}{H} \right) \delta \rho_{1\sigma} - \frac{1}{2} \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \delta \rho_1 = 0, \]  
(A.7)
\[ \delta \rho'_{1\gamma} + 4 \Delta \rho_{1\gamma} - \frac{1}{2} \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \delta \rho_1 = 0 \]  
(A.8)
and at second order
\[ \delta \rho'_{2\sigma} + \left( 3 + \frac{\Gamma}{H} \right) \delta \rho_{2\sigma} - \frac{1}{2} \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \delta \rho_2 + \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \left( \frac{3}{4} \frac{\delta \rho_1^2}{\rho_0} - \frac{1}{2} \delta \rho_2 \right) = 0, \]  
(A.9)
\[ \delta \rho'_{2\gamma} + 4 \Delta \rho_{2\gamma} - \frac{1}{2} \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \delta \rho_2 + \frac{\Gamma}{H} \frac{\rho_{0\sigma}}{\rho_0} \left( \frac{3}{4} \frac{\delta \rho_1^2}{\rho_0} - \frac{1}{2} \delta \rho_2 \right) = 0. \]  
(A.10)
