The genus Mycobacterium consists of at least more than 150 recognized species (LPSN database last accessed on 13th September 2017) [http://www.bacterio.net/index.html]. Pathogenicity ranges from environmental saprophytes to the pathogenic and health hazard M. tuberculosis. Tuberculosis is one of the leading causes of morbidity and mortality with 1.8 million deaths and 10.4 million new cases every year worldwide and continues to be a public health problem globally. A number of the environmental mycobacterium species, collectively known as non-tuberculosis mycobacteria (NTM), are responsible for many opportunistic infections that are increasingly common among immune-compromised individuals. Speciation is important to ascertain the clinical significance of the mycobacteria isolated. Also, differentiation of the Mycobacterium Tuberculosis Complex (MTC) and NTM has become important due to the rise of infections and antimicrobial resistance in this genus.

Conventional methods of identification include growth characteristics, temperature and rate of growth, colony pigmentation, biochemical reactivity etc. These are laborious, difficult to perform and require additional time after the culture flags positive hence most laboratories find these difficult to adopt in routine settings. Nowadays, positive cultures are identified as MTC based on smear morphology and methods like immunochromatography (MPT64 antigen) wherein NTM is a diagnosis of exclusion. Post-culturing, reliable molecular line probe assay like Geno Type CM/AS (HainKen) permits unrestricted use, distribution, and build upon your work non-commercially.

Keywords: MALDI-TOF MS, Mycobacterium, hsp gene sequencing, liquid culture

The current study was aimed to demonstrate the utility of MALDI-TOF MS for the identification of clinical mycobacterial isolates in a large microbiology laboratory. Further the results of MALDI-TOF MS were validated using gold standard hsp65 gene sequencing. To the best of our knowledge, this is the first comprehensive study from India characterizing various Mycobacterium species by MALDI-TOF MS and sequencing on isolates grown in liquid culture.

A total of 56 archived isolates and 4 CAP proficiency isolates were tested in this study. MALDI-TOF MS and hsp65 gene sequencing showed agreement in 52 of 60 isolates (86.67%). All the 4 CAP proficiency panel isolates gave expected results by both the methods. Of the 08 unidentified isolates, 5 were not present in VITEK-MS Database v.3.0, but hsp65 gene sequencing could identify them as M. paratuberculosis (N=2), M. paracasei subsp. paracasei (N=1) and M. sp Fl-06083 (N=2). The remaining 3 isolates that were unidentifiable on VITEK-MS turned out to be mixed isolates as revealed by hsp65 gene sequencing. This was possibly due to contamination of culture upon storage.

Overall, MALDI-TOF MS was found to be rapid and cost-effective system for the identification of majority of mycobacterial species. DNA sequencing can be considered as a complementary tool for speciation of rare species and other discrepant isolates.
of 70% formic acid followed by addition of 10μL of 100% acetonitrile and spinning at 4000g for 2 min. One μL of the supernatant was spotted on a MS target slide and subjected to air-dry. The spot was overlaid with 1μL of CHCA (α-cyano-4-hydroxycinnamic acid) matrix solution followed by air-dry. The slide was processed using the VITEK-MS instrument. Mass spectra were analyzed using automatic database within MYLA software (Biomerieux, France). IVDv3.0 database of VITEK-MS was used in our study.

For molecular identification, DNA was extracted from 200μL of liquid culture using QIAamp Blood Mini kit (Qiagen) and suspended in 200μL of elution buffer. An amplicon corresponding with 65-kDa heat shock protein gene (hsp65) was amplified using primers TB11 \(5\prime\)-ACCAACGATGGTGTGCCAT-3\prime and TB12 \(5\prime\)-CTTGTGCAACCGCATACCCT-3\prime described by Telenti PCR was performed in 20μL containing KAPA Ready Mix (Kapa Biosciences). 10pmol of each primer and 3μL of DNA prep. The PCR consisted of 95°C for 5min followed by 35 cycles at 94°C for 15s, 60°C for 30s, 72°C for 60s and an extension at 72°C for 7min. PCR was followed by bidirectional sequencing on 3500Dx Genetic Analyzer (Applied Biosystems). The mycobacterial sequence was compared with other mycobacterial sequences and species showing ~99% homology through NCBI Gen Bank database.

A total of 60 isolates, representing 17 species belonging to 8 groups of Mycobacteria were used to assess the performance and clinical validity of the MALDI-TOF MS system. These isolates were grown in mycobacterium growth indicator tubes (MGIT), the media commonly used for mycobacteria isolation in corresponding laboratory. In order to validate our results, the same clinical isolates were subjected to hsp65 gene sequencing separately.

MALDI-TOF and hsp65 genes sequencing showed identical results in 52/60 (86.67%) of cases (Table 1) and 8 (13.3%) isolates remained unidentified. All the four CAP proficiency isolates i.e. each one of M. gordonae, M. xenopi, M. marinum and M. intracellulare gave expected results by both the methods. Of the eight unidentified isolates, five of the isolates were identified as M. paraense \(N=2\), M. parascrofulaceum \(N=1\) and M. sp FI-06083 \(N=2\) by hsp65 gene sequencing. These isolates remained unidentified by mass spectrometry since they were not recognized by the IVDv3.0 database of VITEK-MS (Table 1). The remaining 3 unidentified isolates provided mixed sequence data indicating presence of mixed culture. Further analysis of sequence data identified presence of M. intracelullare+M. parascrofulaceum, M. abscessus+M. fortuitum and M. abscessus+M. intracellulare respectively (Table 2). Culturing microorganisms as pure culture is prerequisite for MALDI-TOF MS-based identification since cross-contaminated or mixed cultures can lead to ambiguous and confusing results. Ferreira and coworkers have reported the inability of MALDI-TOF MS to accurately identify mixed bacteria.

Another observation corresponds with group of M. fortuitum. While hsp65 gene sequencing accurately identified seven cases of M. fortuitum and each one of M. porcinum, M. peregrinum and M. conceptionense, MALDI-TOF MS collectively identified all of these 10 microorganisms as M. fortuitum group. The members of M. fortuitum clade include M. fortuitum, M. peregrinum, M. senegalense, M. mageritense, M. septicum, M. alvei, M. houstonense, M. boenickei, M. conceptionense, M. porcinum, M. nevroleusense and M. brashanense. These are rapidly-growing opportunistic human pathogens that cause a wide spectrum of clinically significant symptoms. M. porcinum, a rapidly-growing pathogenic species of human has been reported to cause post-traumatic or post-surgical wound infections, osteomyelitis, and catheter-related infections. M. conceptionense has been reported to cause infection after breast implant surgery as well as a subcutaneous abscess in an immune-competent patient. Reports also reveal that they are resistant to most first-line anti-tuberculous agents. It is therefore important for practitioners to be aware of these rapidly-growing opportunistic and pathogenic microorganisms as possible etiological agents.

| Organism | Total | Results of MALDI-TOF MS system | Results of hsp65 gene sequencing |
|----------|-------|-------------------------------|--------------------------------|
| M. abscessus | 18  | 18  | 18  |
| M. avium  | 1    | 1   | 1   |
| M. chelonea | 1    | 1   | 1   |
| M. fortuitum | 10  | 10  | 10* |
| M. gordonae | 2    | 2   | 2   |
| M. intracellulare | 7  | 7   | 7   |
| M. kansasii | 2    | 2   | 2   |
| M. lentiflavum | 1   | 1   | 1   |
| M. marinum | 1    | 1   | 1   |
| M. scrofulaceum | 1  | 1   | 1   |
| M. simiae  | 5    | 5   | 5   |
| M. smegmatis | 1    | 1   | 1   |
| M. tuberculosis | 1  | 1   | 1   |
| M. xenopi | 1    | 1   | 1   |
| M. paracellulare | 2  | 0   | 2   |
| M. parascrofulaceum | 1  | 0   | 1   |
| M. sp FI-06083 | 2  | 0   | 2   |

*a*hsp65 gene sequencing further identified M. porcinum, M. peregrinum and M. conceptionense from M. fortuitum group of Mycobacteria.

| Sr. no | Group | Species | Count |
|-------|-------|---------|-------|
| 1     | Mycobacterium Chelonea | M. abscessus | 18 |
| 2     | Mycobacterium avium complex (MAC) | M. avium | 1 |
| 3     | Mycobacterium fortuitum | M. fortuitum | 10 |
| 4     | Mycobacterium gordonae | M. gordonae | 2 |
| 5     | Mycobacterium kansasii | M. kansasii | 2 |
| 6     | Mycobacterium simiae | M. simiae | 5 |
| 7     | Mycobacterium tuberculosis complex (MTC) | M. tuberculosis | 1 |

MALDI-TOF MS for rapid identification of Mycobacterium species in liquid culture media

Table Continued

| Sr. no | Group                  | Species            | Count |
|-------|------------------------|--------------------|-------|
| 8     | Other Mycobacteria     | M. marinum RI      | 1     |
|       |                        | M. scrofulaceum RII| 1     |
|       |                        | M. smegmatis        | 1     |
|       |                        | M. xenopi           | 1     |

Although the number of isolates in our study was not large enough (N=60) and the number of species was lower (N=17), our results show that identification using MALDI-TOF is reliable in majority of clinically-relevant species of NTM (M. avium, M. intracellulare, M. abscessus, M. chelonae, M. fortuitum, M. kansasii, M. scrofulaceum). Several studies have documented the effect of culture time on the accuracy of identifying mycobacterial species. Few authors have found dissimilarities in identification depending upon the culture media used, the culture growth time, the extraction protocol applied to the mycobacteria, or the library (i.e. Bruker Biotyper and Vitek MS databases) used. Our results were obtained from clinical isolates, where most of them were assayed within 2-5 days of growth in MGIT liquid medium.

Our study demonstrated that besides low cost and accuracy, MALDI-TOF MS procedure involves little handling and few working hours, which reduces the potential risk of infections caused by mycobacteria in the laboratory. MALDI-TOF MS could be regarded as an alternate diagnostic tool for identification and differentiation of clinical isolates of Mycobacterium. Sequence-based identification remains a complimentary approach for evaluation of unidentified isolates. In order to have comprehensive clinical diagnosis, Sanger sequencing and/or Next Generation Sequencing technology can be utilized by clinical laboratories.
