Abstract

Antioxidant activities of eight indigenous cyanobacterial strains belonging to the genera Oscillatoria, Chroococcidiopsis, Leptolyngbya, Calothrix, Nostoc and Phormidium were studied in relation with their phenolic and flavonoid contents, ranging from 3.9-12.6 mg GAE g⁻¹ and 1.7-3.44 mg RE g⁻¹. The highest activities were shown by Leptolyngbya sp. SI-SM (EC₅₀ = 63.45 and 67.49 µg ml⁻¹) and Calothrix sp. SI-SV (EC₅₀ = 65.79 and 69.38 µg ml⁻¹) calculated with ABTS and DPPH assays. Significant negative correlations were seen between total phenolic and flavonoid contents and the antioxidant activities in terms of EC₅₀ values. Furthermore, HPLC detected fifteen phenolic compounds with total concentrations ranging from 277.3-829.7 µg g⁻¹. The prevalent compounds in most of the strains were Rutin, Tannic acid, Orcinol, Phloroglucinol and Protocatechuic acid. Cyanobacterial strains showed high potential as a good source of phenolic compounds with potent antioxidative potential which could be beneficial for food, cosmetic and pharmaceutical industries.

Keywords: Antioxidation; Phenolics; Flavonoids; ABTS; DPPH; HPLC.
Experimental

1. Growth and Cultivation of Cyanobacteria

To study the antioxidation potential of phenolic compounds produced by cyanobacteria, eight different strains of cyanobacteria: *Oscillatoria* sp. SI-SA (GenBank accession no. KJ755069.1), *Oscillatoria* sp. SI-SF (GenBank accession no. KJ755070.1), *Chroococcidiopsis* thermalis SI-ST (GenBank accession no. KJ755066.1), *Leptolyngbya* sp. SI-SM (GenBank accession no. KJ755064.1), *Calothrix* sp. SI-SV (GenBank accession no. KJ755062.1), *Nostoc* sp. SI-SN (GenBank accession no. KJ755063.1), *Oscillatoria* sp. SI-SK (GenBank accession no. KJ690262.1) and *Phormidium* sp. SI-SC (GenBank accession no. KJ755065.1) were selected, previously isolated and purified from different environmental sources. They were identified morphologically and with 16s rRNA gene sequencing. The sequence was then analyzed with BLASTN database (the details will be discussed in a subsequent study). The strains were grown in 500ml Erlenmeyer flasks containing 250ml of sterilized BG-11 media having pH of 7.6. Cyanobacterial strains were grown for 60 days in an Infors HT Multitron shaking incubator under continuous low intensity white fluorescent light of 80 µE m⁻² s⁻¹ measured with a scalar PAR meter (Biospherical Instruments, Inc. QSL-2100) at 28°C and 50 rpm.

2. Harvest and Extraction

The cyanobacterial biomass obtained was harvested through high speed centrifugation (Sigma 3K30) at 25,000xg for 30 min at 4°C. The biomass was washed twice with sterile distilled water and then quickly frozen with liquid nitrogen. The frozen biomass was then lyophilized (Christ Alpha 2-4 LD) under reduced pressure of 0.040 mbar at -83°C and then stored at -20°C until further use. 0.1 g freeze dried biomass was homogenized and ultra-sonicated on ice for 15 minutes with 5 breaks in 10 ml of 70% methanol. The extracts were kept at 4°C overnight in the dark for complete extraction after which they were centrifuged two times to remove the cell debris. They were then passed through 0.45 µm sterile filter.

3. Total Phenolic Content

The total phenolics were estimated in a 96-well flat bottom micro-titer plate by a method described by Herald et al. (2012) with some modifications. Briefly, to each of the 96 wells, 75 µl of milli-Q water was added followed by 25 µl of sample, standard or blank. After mixing, 25 µl
of diluted (1:1) Folin-Ciocalteu reagent was added to the mixture. After 6 minutes of incubation in the dark, 100 µl of 75 mg ml⁻¹ sodium carbonate solution was added to each well. The solutions were mixed and the plates were covered and left in dark for 90 minutes. The absorbance of the colored product formed was measured with a micro-well plate reader at 765nm. The concentrations of total phenolics were then analysed with the linear regression equation obtained from the means ± SEM of standard calibration curve of Gallic acid (Figure S4). The results were expressed as mg GAE g⁻¹ dry weight.

4. **Total Flavonoid Content**

The flavonoids were estimated in a 96-well flat bottom micro-titer plate by a method described by Herald et al. (2012) with slight adjustments. Firstly, 150 µl of 95% ethanol was added to the wells followed by 50 µl of extracts, standard or blank. After that 10 µl of 100 mg ml⁻¹ aluminum chloride solution was added followed by 10 µl of 1M potassium acetate solution. 95% ethanol was used as a blank. The mixture was then incubated at room temperature in dark for 40 minutes after which absorbance was recorded at 415nm with the help of a micro-well plate reader. The concentrations of total flavonoids were then analysed with the linear regression equation obtained from the means ± SEM of standard calibration curve of Rutin (Figure S5). The results were expressed as mg RE g⁻¹ dry weight.

5. **Antioxidation Assay**

The free radical scavenging activity of phenolic extract was analyzed by ABTS and DPPH assays in 96-well plates using the methods described by Re et al. (1999) and Fukumoto and Mazza (2000) respectively. Trolox and Ascorbic acid were used as standard antioxidants. The percentage scavenging effect was calculated as:

\[
\% \text{ Scavenging Activity} = \left[\frac{(A_{\text{control}} - A_{\text{sample or standard}})}{A_{\text{control}}}\right] \times 100.
\]

The antioxidation activities were expressed in terms of EC₅₀ values which is a concentration of cyanobacterial extracts or standards at which 50% of the free radical was scavenged. EC₅₀ values were calculated with non-linear regression analysis.
6. **RP-HPLC UV/VIS Analysis of Phenolic and Flavonoid Content.**

The analysis of phenolic and flavonoid compounds in cyanobacterial extract was done with HPLC system (Sykam) equipped with UV/VIS detector (Sykam S3210), dual pump system (Sykam S1122), temperature control module (Sykam S4011), pump control module (Sykam), and RP-C18 column (250 x 4.6mm Hypersil ODS 5 µm particle size). The peaks were analysed with integrated software clarity. The mobile phase consisted of methanol and water (95:5) and the flow rate was adjusted to 1ml min⁻¹. The analysis was run at ambient temperature. The crude phenolic extracts and standard phenolic and flavonoid compounds were diluted with absolute methanol (HPLC grade) and 25µl of each sample was loaded with a micro syringe. Each sample was run for 20 min and the absorbance was recorded at 280nm. The phenolic compounds were detected by comparing the peaks in the crude extracts with those of standards.

7. **Statistical Analysis**

The experiments included three technical replicates with three independent experiments (n=3). The standard calibration curves were made with Microsoft Excel 2010. The EC₅₀ and regression analysis and correlations were determined by using GraphPad prism version 5.01. The correlations were analysed with one-way analysis of variance (ANOVA) under Tukey's multiple comparison test. Significant difference was expressed at p < 0.05.
