Improved Upper Bound for the Redundancy of Fix-Free Codes
Sergey Yekhanin

Abstract—A variable-length code is a fix-free code if no codeword is a prefix or a suffix of any other codeword. In a fix-free code any finite sequence of codewords can be decoded in both directions, which can improve the robustness to channel noise and speed up the decoding process. In this paper we prove a new sufficient condition of the existence of fix-free codes and improve the upper bound on the redundancy of optimal fix-free codes.

Index Terms—Fix-free code, redundancy.

I. INTRODUCTION

Let \( p = \{p_1, \ldots, p_m\} \) be the probability distribution of a source, and let \( C \) be a code for the source. The redundancy \( R \) of a code \( C \) is defined as the difference between the average codeword length \( L(C) \) of this code and the entropy \( H(p) \) of the source. We denote the redundancy of an optimal fix-free code by \( R_f \).

Ahlswede et al. [1] have proved that \( 0 \leq R_f < 2 \). They have also shown that the lower bound 0 on \( R_f \) cannot be improved. Later Ye and Yeung [6], [7] derived several upper bounds on \( R_f \) in terms of partial information about the source distribution. The goal of this paper is to improve the upper bound on \( R_f \) from 2 to \( 4 - \log_2 5 \), which is approximately 1.678.

Let \( v_n = (k_1, \ldots, k_n) \) be a vector, where \( k_i \) are nonnegative integers. By \( C(v_n) \) denote a binary variable-length code containing \( k_i \) codewords of length \( i \), for each \( i = 1, n \). The Kraft sum of the vector \( v_n \) is the quantity

\[
S(v_n) = \sum_{i=1}^{n} \frac{k_i}{2^i}.
\]

Ahlswede et al. [1] conjectured that \( S(v_n) \leq \frac{3}{4} \) is a sufficient condition for the existence of a binary fix-free code \( C(v_n) \). They proved that the conjecture is true in the weaker case when the Kraft sum is at most \( \frac{1}{2} \). If the conjecture is true the upper bound on \( R_f \) can be improved to \( 3 - \log_2 3 \), which is approximately 1.415 [7]. Since the conjecture was made, several special cases of it were proven [4], [5], [7], [8], although the general conjecture still remains an open problem.

In this paper we prove a new sufficient condition of the conjecture. We show that \( S(v_n) \leq \frac{3}{4} \) implies the existence of a fix-free code \( C(v_n) \) (Theorem 1). This result yields an improved upper bound for the redundancy of optimal fix-free codes (Theorem 2).

II. NEW SUFFICIENT CONDITION OF THE EXISTENCE OF FIX-FREE CODES

Let \( w \) be an arbitrary binary vector of length \( n \). The binary vector composed of the first \( \{0, 1\} \) symbols of \( w \) is called \( p \)-prefix \( (p \)-suffix \) of \( w \) and denoted by \( \overleftarrow{w} \) \( \overrightarrow{w^p} \). We say that vector \( w \) has the form \( \alpha \star \beta \), where \( \alpha, \beta \in \{0, 1\} \) if \( \overrightarrow{1w} = \alpha \) and \( \overleftarrow{1w} = \beta \).

Consider a binary variable-length fix-free code \( C(v_n) \), where \( v_n = (k_1, \ldots, k_n) \).

A vector \( w \in \{0, 1\}^n \) is called prefix free \{suffix free\} over code \( C(v_n) \) if \( C(v_n) \) does not contain any prefix \{suffix\} of \( w \).

By definition, put

\[
\overrightarrow{0}F(C) = \{w|w \text{ is prefix-free over} C \text{ and } w^1 = 0\},
\overrightarrow{1}F(C) = \{w|w \text{ is prefix-free over} C \text{ and } w^1 = 1\},
\overleftarrow{0}F(C) = \overrightarrow{0}F(C) \cup \overrightarrow{1}F(C),
\overleftarrow{1}F(C) = \overrightarrow{0}F(C) \cup \overrightarrow{1}F(C).
\]

Let \( M \) be an arbitrary subset of \( \{0, 1\}^n \).

The set \( M \) is called right regular if all \( (n - 1) \)-suffixes of words from \( M \) are pairwise distinct, i.e., \( \forall c_1, c_2 \in M, \ c_1 \neq c_2 \) implies \( c_1^{n-1} \neq c_2^{n-1} \).

Similarly, the set \( M \) is called left regular if all \( (n - 1) \)-prefixes of words from \( M \) are pairwise distinct, i.e., \( \forall c_1, c_2 \in M, \ c_1 \neq c_2 \) implies \( c_1^{n-1} \neq c_2^{n-1} \).

Clearly, \( \overrightarrow{0}F(C) \) and \( \overrightarrow{1}F(C) \) are right regular sets. Likewise, \( \overleftarrow{0}F(C) \) and \( \overleftarrow{1}F(C) \) are left regular sets.

Let \( M_1 \) and \( M_2 \) be arbitrary subsets of \( \{0, 1\}^n \). By definition, put

\[
M_1 \otimes M_2 = \{w \in \{0, 1\}^{n+1} | \overrightarrow{w} \in M_1 \text{ and } \overleftarrow{w^n} \in M_2\}
\]

The following lemma is obvious.

**Lemma 1:** Suppose \( C(v_n) \) is an arbitrary fix-free code; then \( \overrightarrow{F(C)} \otimes \overleftarrow{F(C)} \) is the set of all words of length \( n + 1 \) that can be added to \( C(v_n) \) without violation of the fix-free property of the code. Moreover, \( \overrightarrow{F(C)} \otimes \overleftarrow{F(C)} \) is the set of all words of the form \( \alpha \star \beta \) and length \( n + 1 \) that can be added to \( C(v_n) \) without violation of the fix-free property of the code.

**Lemma 2:** Suppose \( M_1 \) is a right regular subset of \( \{0, 1\}^n \) and \( M_2 \) is a left regular subset of \( \{0, 1\}^n \); then

\[
|M_1 \otimes M_2| \geq |M_1| + |M_2| - 2^{n-1}.
\]
Proof: By $M_1^{(n-1)}$ denote the set of $(n-1)$-suffixes of words from $M_1$. In the same way, by $(n-1)M_2$ denote the set of $(n-1)$-prefixes of words from $M_2$. Since $M_1$ is right regular, it follows that $|M_1^{(n-1)}| = |M_1|$. Similarly, $|M_1^{(n-1)}| = |M_2|$. Since $M_1^{(n-1)}$ and $(n-1)M_2$ are subsets of $(0,1)^{n-1}$, it follows that $|M_1^{(n-1)} \cup (n-1)M_2| \leq 2^{n-1}$. Therefore, $|M_1^{(n-1)} \cap (n-1)M_2| \geq |M_1| + |M_2| - 2^{n-1}$. Let $b$ denote an arbitrary element of $M_1^{(n-1)} \cap (n-1)M_2$. It now follows that there exist $a, c \in \{0,1\}$ such that $ab \in M_1$ and $bc \in M_2$. Hence, $abc \in M_1 \otimes M_2$. Thus, $|M_1 \otimes M_2| \geq |M_1| + |M_2| - 2^{n-1}$. This completes the proof.

Theorem 1: If $S(v_n) \leq \frac{3}{2}$, then there exists a fix-free code $C(v_n)$. Proof: Clearly, it suffices to prove that $S(v_n) = \frac{3}{2}$ implies the existence of a fix-free code $C(v_n)$. Let us consider three cases.

1) $k_1 = 1$
2) $k_1 = 0, k_2 = 2$
3) $k_1 = 0, k_2 \leq 1$

In every case we construct the code $C(v_n)$ in $n$ steps. On step $t$ we add $k_t$ words of length $t$ to the code. The input of step $t$ is a code $C(v_t-1)$, the output is a code $C(v_t)$. Thus, on step $n$ we construct $C(v_n)$.

Proof of case 1: We shall now prove that $S(v_n) \leq \frac{3}{4}$ and $k_1 = 1$ imply the existence of a fix-free code $C(v_n)$. This claim is stronger than the assertion of the theorem. Suppose that a fix-free code $C = C(v_{t-1})$ is constructed; we shall prove that on step $t$ we can add $k_t$ words of length $t$ to the code without violation of the fix-free property. By lemma 1, it is sufficient to prove that $|F(C) \otimes F(C)| \geq k_t$. Put $\delta = S(v_{t-1})$. Using (1), we get $\delta + \frac{3}{2} \leq \frac{3}{4}$. Hence,$$k_t \leq 3 \cdot 2^{t-2} - \delta \cdot 2^t.$$ (3)
Now note that since $0 \in C(v_{t-1})$, it follows that $0 F(C) = F^0(C) = 0$. Therefore, $F(C)$ is right regular and $F(C)$ is left regular. It can be easily checked that $|F(C)| = |F(C)| = 2^{t-1}(1 - \delta)$. The application of lemma 2 yields$$(|F(C) \otimes F(C)|) \geq 3 \cdot 2^{t-2} - \delta \cdot 2^t.$$ (4)
Combining (3) and (4), we obtain $|F(C) \otimes F(C)| \geq k_t$. This completes the proof of the first case of Theorem 1.

Proof of case 2: We shall now prove that $S(v_n) \leq \frac{3}{4}$, $k_1 = 0$ and $k_2 = 2$ imply the existence of a fix-free code $C(v_n)$. Again, our claim is stronger than the assertion of the theorem. Suppose that a fix-free code $C = C(v_{t-1})$ is constructed; we shall prove that $|F(C) \otimes F(C)| \geq k_t$. It is sufficient to prove that both inequalities (3) and (4) are fulfilled. The proof of inequality (3) is exactly the same as above, so we proceed to inequality (4).

Let us show that $F(C)$ is right regular. Assume the converse. Then there exists a vector $b \in \{0, 1\}^{t-2}$ such that both words $0b$ and $1b$ are prefix free over $C(v_{t-1})$. Let us consider the two cases $1b = 0$ and $1b = 1$ separately. In the first case $0b$ is prefixed by the codeword $00$. In the second case $1b$ is prefixed by the codeword $11$. Thus, we have come to a contradiction. By the same argument, $F(C)$ is left regular.

As above, $|F(C)| = |F(C)| = 2^{t-1}(1 - \delta)$. The application of lemma 2 yields. This completes the proof of the second case of Theorem 1.

Proof of case 3: Since $k_1 = 0$ and $k_2 \leq 1$, it follows that the vector $v_n$ can be uniquely represented as a sum of four vectors $v^1_n, v^2_n, v^3_n, v^4_n$ such that

$$\begin{align*}
&v^1_n = \{1, \ldots, k_i\}, \quad i = 1, 2, 3, 4, \\
&v^2_n = S(v^1_n) = S(v^3_n) = \frac{1}{3}, \\
&v^3_n = \{0, 0, 0, 0, 0, 0\}, \\
&v^4_n = \{0, 0, 0, 0, 0, 0, 0, 0\}.
\end{align*}$$

Consider the following example of such representation.

$$v_n = \{0, 0, 2, 1, 2, 6, 20\} \quad S(v_n) = \frac{5}{8},$$
$$v^1_n = \{0, 0, 2, 0, 0, 0, 0\} \quad S(v^1_n) = \frac{1}{4},$$
$$v^2_n = \{0, 0, 0, 1, 2, 0\} \quad S(v^2_n) = \frac{5}{16},$$
$$v^3_n = \{0, 0, 0, 0, 0, 4\} \quad S(v^3_n) = \frac{1}{2},$$
$$v^4_n = \{0, 0, 0, 0, 0, 0, 16\} \quad S(v^4_n) = \frac{1}{4}.$$
The application of lemma 2 yields
\[ |0 F(C) \otimes F(C)| \geq 2^{t-2} - \delta_1 \cdot 2^t \geq k_1^1, \]
\[ |0 F(C) \otimes F(C)| \geq 2^{t-2} - \delta_1 \cdot 2^{t-1} \geq k_2^1, \]
\[ |1 F(C) \otimes F(C)| \geq 2^{t-2} - \delta_1 \cdot 2^{t-1} \geq k_3^1, \]
\[ |1 F(C) \otimes F(C)| \geq 2^{t-2} > k_4^1. \]

This completes the proof of case 3.1.

**Case 3.2:** \( \delta_1 = \frac{1}{4}, \delta_2 < \frac{1}{8}, \delta_3 = \delta_4 = 0. \) By the same argument as above
\[ k_1^1 = 0, \quad k_2^1 \leq 2^{t-3} - \delta_2 \cdot 2^t, \]
\[ k_3^1 \leq 2^{t-3}. \]

We see that
\[ |0 F(C)| = 2^{t-2} - (\frac{1}{4} + \delta_2) \cdot 2^{t-1}, \]
\[ |0 F(C)| = 2^{t-3}, \]
\[ |1 F(C)| = 2^{t-2} - \delta_2 \cdot 2^{t-1}. \]

By lemma 2, we have
\[ |0 F(C) \otimes F(C)| \geq 2^{t-3} - \delta_2 \cdot 2^t \geq k_2^2, \]
\[ |1 F(C) \otimes F(C)| \geq 2^{t-3} \geq k_3^2, \]
\[ |1 F(C) \otimes F(C)| \geq 2^{t-2} - \delta_2 \cdot 2^{t-1} > 2^{t-3} \geq k_4^2. \]

This completes the proof of case 3.2.

**Case 3.3:** \( \delta_1 = \frac{1}{4}, \delta_2 = \frac{1}{8}, \delta_3 < \frac{1}{8}, \delta_4 = 0. \) As above,
\[ k_1^2 = 0, \quad k_2^2 = 0, \]
\[ k_3^2 \leq 2^{t-3} - \delta_3 \cdot 2^t, \quad k_4^2 \leq 2^{t-3}. \]

It is easily shown that
\[ |0 F(C)| = 2^{t-3} - \delta_3 \cdot 2^{t-1}, \]
\[ |1 F(C)| = 2^{t-2} - \delta_3 \cdot 2^{t-1}, \]
\[ |F(C)| = 3 \cdot 2^{t-4}. \]

Applying lemma 2, we obtain
\[ |1 F(C) \otimes F(C)| \geq 2^{t-3} - \delta_3 \cdot 2^t \geq k_3^3, \]
\[ |1 F(C) \otimes F(C)| \geq 3 \cdot 2^{t-4} - \delta_3 \cdot 2^{t-1} > 2^{t-3} \geq k_4^3. \]

This completes the proof of case 3.3.

**Case 3.4:** \( \delta_1 = \frac{1}{4}, \delta_2 = \frac{1}{8}, \delta_3 = \frac{1}{8}, \delta_1 < \frac{1}{8}. \) As above,
\[ k_1^4 = 0, \quad k_2^4 = 0, \]
\[ k_3^4 \leq 2^{t-3} - \delta_4 \cdot 2^t. \]

One can easily see that
\[ |1 F(C)| = |F(C)| = 2^{t-2} - (\frac{1}{8} + \delta_4) \cdot 2^{t-1}. \]

By lemma 2, we have
\[ |1 F(C) \otimes F(C)| \geq 2^{t-3} - \delta_4 \cdot 2^t \geq k_4^4. \]

This completes the proof of the theorem.
