Abstract

We show that the Higgs boson structure functions observable in the inclusive process $e^- e^+ \rightarrow H + \text{“anything”}$, may reveal the presence of anomalous contributions corresponding to several types of new physics partners, Higgs boson compositeness, or invisible (dark) matter. This could be done without making a difficult or even an impossible experimental analysis of what “anything” contains. We give illustrations showing how the shapes of the various structure functions induced by such new contributions may differ from the standard predictions, thus possibly allowing their identification.

1 Introduction

The discovery [1] of the Higgs boson [2] is a great step towards the verification of the standard model (SM) [3]. Nevertheless there are several experimental (muon g-2, neutrino masses, dark matter) and theoretical (hierarchy problem,...) points which are not covered by SM [4]. Many ways, of very different nature, have been proposed for making a fruitful extension of SM, like supersymmetry, additional strong sectors, compositeness, and dark sectors, globally called “beyond the standard model” (BSM) [5].

Here we want to turn in particular to the difficulty in analyzing the mechanisms responsible for producing multiparticle or invisible states, in particular dark matter, in association with the Higgs particle. Indeed, the Higgs boson may couple to several new particles and may be a portal to such new sectors [6]. So we thought that a possible hint may arise if we look at the “Higgs structure functions” in the inclusive process \( e^-e^+ \rightarrow H(p_H^0) + X \), where \( p_H^0 \) denotes the \( H \)-four-momentum, \( s \) describes the total \( e^-e^+ \) c.m. energy-squared, and \( X \) stands for an additional final state with two or more particles. We ignore contributions where \( X \) is a single particle associated to \( H \) (for example \( e^-e^+ \rightarrow HZ \)); since it is localized at a single point near the end of the spectrum, with the c.m. \( H \)-energy being \( p_H^0 = (s + m_H^2 - m_Z^2)/(2\sqrt{s}) \). Instead, we are rather interested by the shapes of the structure functions versus \( s \) and \( p_H \).

At LHC, there may also be other similar inclusive processes, where the Higgs-particle is produced in association with new particles. But in this paper we only consider the \( e^-e^+ \) process, which is probably the simplest and clearest one phenomenologically.

In particular, if the \( X \)-state mentioned above is generated through an \( s \)-channel intermediate state \((V = \gamma, Z)\), as in

\[
e^-e^+ \rightarrow V(\gamma, Z) \rightarrow H(p_H^0) + X \ ,
\]

(1)

which is true for the BSM models used here and partly also for SM, then the general form of the cross section for any \( e^-e^+ \)-polarizations, may be described by just three structure functions \( W_i \) \((i = 1, 2, 3)\). These \( W_i \) functions may then be chosen to depend only on \( s \) and the c.m. magnitude of the \( H \) momentum [7].

In Sect.2 we give the definitions of these functions and recall the relations among the three \( W_i \), induced by the quantum numbers of the particles associated to the \( H \) production. In Sect.3 we show how they can be simply measured through the angular distribution of the \( H \)-inclusive cross section in the \( e^-e^+ \) unpolarized and polarized cases. In Sect.4 we compute their standard contributions, where the 2-body \( X \) (“anything”) state associated to \( H \), is due to the usual fermion pairs (\( t\bar{t} \) and the light \( f\bar{f} \) ones) and the \( ZH \) bosons.

We treat separately the case \( X = W^-W^+ \), which can only partly be described by the form [1]; since now one has to add the \( t \)-channel neutrino exchange amplitude, followed by a \( W^\pm W^\mp H \) coupling. We also include separately the similar \( t \)- and \( u \)-channel electron exchange processes \( e^-e^+ \rightarrow ZZ \) and \( e^-e^+ \rightarrow Z\gamma \) followed by a \( ZZH \) coupling.

For simplicity, we ignore the contributions of the \( ZZ \) and \( W^-W^+ \) fusion processes \( e^-e^+ \rightarrow e^-e^+H \) and \( e^-e^+ \rightarrow \nu_e\bar{\nu}_eH \) (see [8]), since these processes can be considered as
a “background” which may be subtracted from the data before making the analysis we propose.

In Sect.5 we then give typical examples of possible new physics contributions; i.e. production of new bosons or fermions emitting the Higgs boson, either in the form of additional associated two-body contributions of type \[1\], or in a form similar to the hadronic parton model in the case of Higgs boson compositeness. We then show how the structure functions \(W_i\) depend on the nature of the associated particles, and on their parameters (masses, couplings). In particular we show how the shapes of the \(s\) and \(p_H\) dependencies of the various \(W_i\) are affected by the nature of the associated particles, which are generally difficult to detect directly. Several illustrations for the various combinations of these structure functions are given.

Summarizing, the contents of the paper are the following. In Sect.2 we give the precise definition of the structure functions. In Sect.3 we express their measurability through the angular dependencies of the polarized and unpolarized cross sections. Sect.4 is devoted to the theoretical computation and illustrations of the SM contributions to the structure functions, while Sect.5 concentrates in some examples of new physics effects. Conclusions mentioning possible future developments are given in Sect.6.

## 2 Structure functions

The cross section of the process \(1\) may be written as \[7\]

\[
\sigma = \frac{(2\pi)^4}{2s} \int d\rho L_{\mu\nu}^\alpha H_{\alpha\beta}^{\mu\nu},
\]

where \(L_{\mu\nu}^\alpha\) arise from the square of the initial vertex and the \(\gamma, Z\) propagators, while \(H_{\alpha\beta}^{\mu\nu}\) comes from the final part \(\gamma, Z \rightarrow H + X\), containing the Higgs structure functions; \(\alpha, \beta\) refer to \(\gamma\) or \(Z\). Denoting by \(p_H^\mu\) the four-momentum of the final H-particle, and by \(q^\nu\) the \(e^-\bar{e}^+\)-total four-momentum, we define

\[
d\rho = \frac{d^3p_H}{2(2\pi)^3 p_H^0} d\rho_X,
\]

with \(d\rho_X\) containing the phase-space of the final X-state. Using this, one writes

\[
\int d\rho_X H_{\alpha\beta}^{\mu\nu} = \frac{1}{(2\pi)^3} W_{\alpha\beta}^{\mu\nu} \sum_i I_i^{\mu\nu} W_i^{\alpha\beta}
\]

\[
= -(g^{\mu\nu} - \frac{q^\mu q^\nu}{s}) W_1^{\alpha\beta} + (p_H^\mu - \frac{p_H \cdot q}{s} q^\mu)(p_H^\nu - \frac{p_H \cdot q}{s} q^\nu) \frac{W_2^{\alpha\beta}}{m_H^2} - i\epsilon^{\mu\nu\rho\sigma} p_{H\rho} q_\sigma W_3^{\alpha\beta},
\]

where

\[
I_1 = -(g^{\mu\nu} - \frac{q^\mu q^\nu}{s}) , \quad I_2 = \frac{1}{m_H^2} (p_H^\mu - \frac{p_H \cdot q}{s} q^\mu)(p_H^\nu - \frac{p_H \cdot q}{s} q^\nu) , \quad I_3 = \frac{-i}{m_H^2} \epsilon^{\mu\nu\rho\sigma} p_{H\rho} q_\sigma,
\]

\[1\]See Section 4.
are the only terms that remain non vanishing after contracting with \( L^{\alpha \beta}_{\mu \nu} \); compare (2).

Note that the \( H \) structure functions \( W_{i}^{\alpha \beta} \) in (4), are taken as functions of \( s = q^2 \) and the c.m. magnitude of the \( H \) momentum

\[
p_{H} = \frac{\sqrt{[s - (m_{H} + M_{X})^{2}][s - (m_{H} - M_{X})^{2}]} }{2\sqrt{s}},
\]

where \( M_{X} \) denotes the invariant mass of the \( X \)-state. As a first step we only consider two-body \( X \)-states. At very high energies, multibody \( X \) contributions would probably also be needed.

### \( H+2 \)-body contributions

We start from the transition \( \gamma, Z \rightarrow x + x' \) followed by \( x \rightarrow x'' + H \) or \( x' \rightarrow x'' + H \), where \( x, x', x'' \) can be scalars, fermions or gauge bosons. For each \( X \), one squares the sum over all diagram, obtaining an expression for \( H_{\alpha \beta}^{\mu \nu} \). We then compute its corresponding three numerical quantities,

\[
K_{i}^{\alpha \beta} = \int d\rho_{X} H_{\alpha \beta}^{\mu \nu} I_{i}^{\mu \nu},
\]

by integrating the \( I_{i}^{\mu \nu} \)-expressions in (5). Denoting the respective momenta of \((x', x'')\) as \((p', p'')\), we have

\[
d\rho_{X} = \frac{1}{4(2\pi)^6} \frac{d^3p'd^3p''}{p^0p'^0p''^0} \delta_4(q - p_{H} - p' - p''),
\]

which through (4) lead to

\[
W_{1}^{\alpha \beta} = \frac{sm_{H}^2}{2[sm_{H}^2 - (p_{H}.q)^2]} \left[ \frac{K_{1}^{\alpha \beta}}{sm_{H}^2} - \frac{(p_{H}.q)^2}{2[sm_{H}^2 - (p_{H}.q)^2]} + K_{2}^{\alpha \beta} \right],
\]

\[
W_{2}^{\alpha \beta} = \frac{sm_{H}^2}{2[sm_{H}^2 - (p_{H}.q)^2]} \left[ \frac{K_{1}^{\alpha \beta}}{sm_{H}^2} - \frac{(p_{H}.q)^2}{2[sm_{H}^2 - (p_{H}.q)^2]} + 3K_{2}^{\alpha \beta} \right],
\]

\[
W_{3}^{\alpha \beta} = \frac{m_{H}^4}{2[sm_{H}^2 - (p_{H}.q)^2]} K_{3}^{\alpha \beta}.
\]

### 3 The \( e^-e^+ \) cross section

Using (2-5) and \( \alpha = e^2/(4\pi) \), the general inclusive cross section for polarized \( e^\mp \) beams is written as

\[
\frac{p_{H}^0 d\sigma(e^-e^+ \rightarrow H + X)}{d^3p_{H}} = \frac{\alpha^2}{s^2} \left\{(1 - P_{L}P'_{L})U_1 + (P_{L} - P'_{L})U_2 + P_{T}P'_{T}(U_3 \cos 2\phi + U_4 \sin 2\phi)\right\},
\]

where \( U_{i} \) are phase space factors defined by (4) and (5).
where \( P_L, P_{L'}, P_T, P_{T'} \) are the longitudinal and transverse \( e^\pm \) beam degrees of polarization and

\[
U_1 = \left( W_1^{\gamma\gamma} + \frac{p_H^2}{2m_H^2}W_2^\gamma\sin^2\theta \right) + \frac{s^2(|g_{Z\gamma e}|^2 + |g_{Z\gamma e}^R|^2)}{2(s - m_Z^2)} \left( W_1^{ZZ} + \frac{p_H^2}{2m_H^2}W_2^{ZZ}\sin^2\theta \right) - \text{Re} \left\{ \frac{s(g_{Z\gamma e}^L + g_{Z\gamma e}^R)}{(s - m_Z^2)} \left( W_1^{\gamma\gamma} + \frac{p_H^2}{2m_H^2}W_2^{\gamma\gamma}\sin^2\theta \right) \right\} \]

\[
+ \frac{s^2(|g_{Z\gamma e}^L|^2 - |g_{Z\gamma e}^R|^2)p_H\sqrt{s}}{2(s - m_Z^2)^2m_H^2}W_3^{ZZ}\cos\theta + \text{Re} \left\{ \frac{s(g_{Z\gamma e} - g_{Z\gamma e}^*)p_H\sqrt{s}}{(s - m_Z^2)m_H^2}W_3^{\gamma\gamma} \right\} \cos\theta ,
\]

\[
U_2 = \frac{s^2(|g_{Z\gamma e}^L|^2 - |g_{Z\gamma e}^R|^2)}{2(s - m_Z^2)^2} \left( W_1^{ZZ} + \frac{p_H^2}{2m_H^2}W_2^{ZZ}\sin^2\theta \right) + \text{Re} \left\{ \frac{s(g_{Z\gamma e}^L + g_{Z\gamma e}^R)}{(s - m_Z^2)^2} \left( W_1^{\gamma\gamma} + \frac{p_H^2}{2m_H^2}W_2^{\gamma\gamma}\sin^2\theta \right) \right\} + \frac{s^2(|g_{Z\gamma e}^L|^2 + |g_{Z\gamma e}^R|^2)p_H\sqrt{s}}{2(s - m_Z^2)m_H^2}W_3^{ZZ}\cos\theta - \text{Re} \left\{ \frac{s(g_{Z\gamma e} + g_{Z\gamma e}^*)p_H\sqrt{s}}{(s - m_Z^2)m_H^2}W_3^{\gamma\gamma} \right\} \cos\theta ,
\]

\[
U_3 = \frac{-p_H^2}{2m_H^2}W_2^{\gamma\gamma}\sin^2\theta - 2\frac{s^2}{2m_H^2(s - m_Z^2)^2m_H^2}W_2^{ZZ}\sin^2\theta + \frac{p_H^2}{2m_H^2(s - m_Z^2)}(s\{g_{Z\gamma e}^L + g_{Z\gamma e}^R\})W_2^{\gamma\gamma}\sin^2\theta ,
\]

\[
U_4 = \frac{p_H^2}{2m_H^2}(s - m_Z^2)\{g_{Z\gamma e} - g_{Z\gamma e}^R\}W_2^{\gamma\gamma}\sin^2\theta .
\]

Note that \( W_1^{\gamma\gamma}, W_1^{ZZ} \) are real, while \( W_1^{\gamma\gamma}, W_1^{ZZ} \) can be complex. Consequently, at tree level and for real photon and \( Z \) couplings, we have \( U_4 = 0 \). Non vanishing contributions to \( U_4 \) may only come from loop corrections or effective \( Z\gamma e \)-form factors.

In Sections 4 and 5 we discuss illustrations of SM and new physics contributions to the \( W_i \) structure functions arising in the unpolarized case, as well as in the cases of \( e^\pm \) beams with only longitudinal or only transverse polarizations; for simplicity we restrict to real couplings. We emphasize that such illustrations apply only to \( X \)-states appearing in transitions of the type \( \pi \).

Therefore, for the formalism based on (11) to apply, special care must be taken, so that the experimental measurements assure the exclusion of \( X \)-states not-generated by \( \gamma, Z \rightarrow H + X \), but rather through \( t \) or \( u \) channel exchanges in \( e^-e^+ \rightarrow H + X \). In the present work such \( X \)-states only appear in the SM contribution, and they are calculated directly; see Section 4.

**\( U_1 \)** determination through unpolarized beams.

Using (10), the differential cross section for unpolarized beams may be written as

\[
d\sigma(e^-e^+ \rightarrow H + X) = \frac{2\pi p_H^2}{p_H^2}d\sigma(e^-e^+ \rightarrow H + X) ,
\]

(12)
where only $U_1$ of (11) contributes. The explicit expression thus obtained consists of a constant (angular independent) term

$$V_1 = W_1^{\gamma\gamma} + \frac{s^2(g_{Zee}^L + g_{Zee}^R)}{2(s - m_Z^2)} W_1^{ZZ} - \frac{s(g_{Zee}^L + g_{Zee}^R)}{(s - m_Z^2)} W_1^{\gamma Z} ,$$

(13)
a term proportional to $\sin^2 \theta$

$$V_2 = \frac{p_H^2}{2m_H^2} \sin^2 \theta \left[ W_2^{\gamma\gamma} + \frac{s^2(g_{Zee}^L + g_{Zee}^R)}{2(s - m_Z^2)^2} W_2^{ZZ} - \frac{s(g_{Zee}^L + g_{Zee}^R)}{(s - m_Z^2)} W_2^{\gamma Z} \right] ,$$

(14)
and a term proportional to $\cos \theta$

$$V_3 = \frac{p_H^2}{2m_H^2} \sin^2 \theta \left[ s(g_{Zee}^L - g_{Zee}^R) p_H \sqrt{s} W_3^{ZZ} + \frac{s(g_{Zee}^L - g_{Zee}^R)}{2(s - m_Z^2)} W_3^{\gamma Z} \right] \cos \theta .$$

(15)

**Longitudinally polarized beams may be used to determine $U_2$.**

Using (10, 11), this is found to consist of the angle-independent term

$$V_4 = \frac{s^2(g_{Zee}^L - g_{Zee}^R)}{2(s - m_Z^2)^2} W_1^{ZZ} + \frac{s(g_{Zee}^L - g_{Zee}^R)}{(s - m_Z^2)} W_1^{\gamma Z} ,$$

(16)
a term proportional to $\sin^2 \theta$

$$V_5 = \frac{p_H^2}{2m_H^2} \sin^2 \theta \left[ s^2(g_{Zee}^L - g_{Zee}^R) p_H \sqrt{s} W_4^{ZZ} + \frac{s(g_{Zee}^L - g_{Zee}^R)}{2(s - m_Z^2)} W_4^{\gamma Z} \right] ,$$

(17)
and a term proportional to $\cos \theta$

$$V_6 = \cos \theta p_H \frac{\sqrt{s}}{m_H^2} \left[ s^2(g_{Zee}^L + g_{Zee}^R) W_6^{ZZ} + \frac{s(g_{Zee}^L + g_{Zee}^R)}{(s - m_Z^2)} W_6^{\gamma Z} \right] .$$

(18)

**Transversally polarized beams may be used to determine $U_3, U_4$:**

Using again (10, 11) and real couplings so that $U_4 = 0$, the obtained cross section is fully determined by

$$V_7 = U_3 = p_H^2 \sin^2 \theta \left[ \frac{-W_2^{\gamma\gamma}}{2m_H^2} - \frac{2s^2 Re\{g_{Zee}^L g_{Zee}^R\} W_2^{ZZ}}{2m_H^2 (s - m_Z^2)^2} + \frac{Re\{s(g_{Zee}^L + g_{Zee}^R) W_2^{\gamma Z}\}}{2m_H^2 (s - m_Z^2)} \right] ,$$

(19)
leading to a $\sin^2 \theta \cos 2\phi$ angular dependence. Such a dependence should simply confirm the property of the $W_2$ structure functions, which of course could also be obtained from $V_2$, but with a different $\gamma, Z$ combination.

Concerning (10, 11, 19), we add the following remarks:
• If $X$ consists of two scalar or two vector particles, then $W_{3}^{\alpha \beta} = 0$. This can be seen from (4, 5) by remarking that the $V$ and $H$ couplings to scalar or vector particles, can never generate a parity violating $I_{3}$ contribution.

• In addition, at high energy and $p_{H}$, in the scalar cases $\gamma, Z \rightarrow s + s'$ followed by $s \rightarrow H + s''$ or $s' \rightarrow H + s''$, the couplings are proportional to $p_{s} - p_{s'}$, so that only an $I_{2}$ contribution survives leading to $W_{1}^{\alpha \beta} \approx 0$.

Correspondingly, in the fermion case $\gamma, Z \rightarrow f + \bar{f}$ followed by $f \rightarrow H + f$ or $\bar{f} \rightarrow H + \bar{f}$, the so-called longitudinal part $(q^{\mu}q^{\nu})$ also vanishes when masses can be neglected in the kinematics, leading to $W_{1}^{\alpha \beta} + (p_{H}^{2}/m_{H}^{2})W_{2}^{\alpha \beta} \approx 0$.

These properties should be useful for identifying the nature of the $X$ states associated with the Higgs boson.

• We recall that:

\[
\begin{align*}
V_{1}, V_{4} & \quad \text{are combinations of} \quad W_{1}^{\gamma \gamma}, W_{1}^{ZZ}, W_{1}^{Z \gamma}, \\
V_{2}, V_{5}, V_{7} & \quad \text{combinations of} \quad W_{2}^{\gamma \gamma}, W_{2}^{ZZ}, W_{2}^{Z \gamma}, \\
V_{3}, V_{6} & \quad \text{combinations of} \quad W_{3}^{ZZ}, W_{3}^{Z \gamma}.
\end{align*}
\]

4 The $H+2$-body contributions in SM

$s$-channel $X$-forms in SM

We first concentrate on the $s$-channel $X$-forms that arise in SM through the process (1). These are

\[X = t\bar{t}, \quad f\bar{f}, \quad ZH, \quad (20)\]

where $f$ contains all leptons and quarks except the $t$-one. For such $X$-forms the general treatment in Sections 2 and 3 fully applies.

For each final state we compute the standard amplitude. By taking its square one obtains the $H^{\mu \nu}$ probability defined in Section 2. In the $t\bar{t}$ case the amplitude is due to 3 diagrams

\[e^{-}e^{+} \rightarrow \gamma, Z \rightarrow t+(\bar{t} \rightarrow \bar{t}+H), \quad e^{-}e^{+} \rightarrow \gamma, Z \rightarrow \bar{t}+(t \rightarrow t+H), \quad e^{-}e^{+} \rightarrow Z \rightarrow H+(Z \rightarrow t\bar{t}) \].

Similar diagrams occur for the light $f\bar{f}$ cases, but in this case the first 2 ones are negligible due to the mass suppressed $Hf\bar{f}$ coupling.

In the case of $ZH$ one has 4 diagrams because the complete amplitude producing the final $ZHH$ is symmetrized by exchange of the two Higgs-particles, before computing the probabilities and the structure functions-particles

\[e^{-}e^{+} \rightarrow Z \rightarrow H(p_{H}) + (Z \rightarrow Z + H(p')) \], \quad e^{-}e^{+} \rightarrow Z \rightarrow H(p') + (Z \rightarrow Z + H(p)) \].

\[\]
and the other (already symmetric) ones
\[ e^-e^+ \rightarrow Z \rightarrow Z + (H \rightarrow H(p_H) + H(p')) , \]
\[ e^-e^+ \rightarrow Z \rightarrow Z + H(p_H) + H(p') , \]
invoking the 4 leg \( ZZHH \) coupling.

We give in Figs.1,2,3 the corresponding SM unpolarized differential cross section \(12\) and the structure functions \(V_1, ... V_7\) appearing in \(13-19\), for each of the \(X\) states in \(20\). In these figures, the \(X = f \bar{f}\) state is always termed as ”light”. In addition to them, we also give the results for the sum of all the \(X\)-states in \(20\), denoted as sSM.

In all Figs.1,2,3 we only give the dependencies on the Higgs momentum \(p_H\), at a specific angle \(\theta = 60^\circ\); this angular specification is only dropped for \(V_1, V_4\) which are angle-independent. Left panels always correspond to \(\sqrt{s} = 1\)TeV, while right panels to \(\sqrt{s} = 5\)TeV.

In more detail, Figs.1 present the SM unpolarized differential cross section and the angle-independent and usually largest \(V_1, V_4\). Figs.2 show the angle-dependent \(V_2, V_3, V_5\), while Figs.3 present \(V_6, V_7\). In all cases, the \(Htt\) contribution is the largest; then comes the \(ZHH\) one, while the light fermions contribution is much smaller.

Note also the differences in the shapes of these contributions, as well as the specific connections among the \(V_1, ... V_7\) mentioned in Section 3. A possible violation of this, may supply hints on an experimental departure from the SM predictions, as we will see in the next section.

**t- and u-channel X-forms in SM**

In addition to the SM \(s\)-channel \(X\) states appearing in \(20\), one has to add the \(X\)-states
\[ X = W^-W^+ , \quad ZZ , \quad Z\gamma \, , \tag{21} \]
which differ by the presence of \(t\) and \(u\) channel neutrino or electron exchanges.

In the case of the \(H + W^-W^+\) final state, in addition to the 3 \(s\)-channel diagrams
\[ e^-e^+ \rightarrow \gamma, Z \rightarrow (W^- \rightarrow W^- + H) + W^+ , \quad e^-e^+ \rightarrow \gamma, Z \rightarrow W^- + (W^+ \rightarrow W^+ + H) \, , \]
\[ e^-e^+ \rightarrow Z \rightarrow H + (Z \rightarrow W^+W^-) , \]
one has the 2 \(t\)-channel neutrino exchange diagrams
\[ e^-e^+ \rightarrow (W^- \rightarrow W^- + H) + W^+ , \quad e^-e^+ \rightarrow W^- + (W^+ \rightarrow W^+ + H) \, . \]

Finally, in the \(ZZ\) and \(Z\gamma\) cases one has only \(t\) and \(u\) electron exchanges and one final \(ZZH\) coupling.

These \(t\) and \(u\) exchanges do not obey \(11\) and thus, they cannot be described in terms of the simple Higgs boson structure functions \(13-19\). Therefore, we treat them separately and we directly compute their contributions to the inclusive cross sections \(d\sigma/dp_H d\cos \theta_H\). They are illustrated in Fig.4 as functions of \(p_H\). In these illustrations we show the contributions of the sum of the \(s\)-channel processes given in \(20\) which has already appeared in the upper panels of Fig.1 (called sSM) and in addition, we also give the contributions
from the X-states in (21). The sum of all X-states in (20,21), which describes the total SM contribution, called SM\textsubscript{tot}, is also given.

As already said, in order to analyze experimental data in terms of the simple Higgs boson structure functions (13-19), one has first to subtract the contributions of the X-forms in (21) from the inclusive experimental contribution to $e^-e^+ \rightarrow H + X$.

The same procedure should be applied for the \textit{ZZ} and $W^-W^+$ fusion processes $e^-e^+ \rightarrow e^-e^+ H$ and $e^-e^+ \rightarrow \nu_e \bar{\nu}_e H$ (see [8]). A priori these should be added to the s-channel processes $e^-e^+ \rightarrow H + (Z \rightarrow e^-e^+, \nu_e \bar{\nu}_e)$. But, since their contribution to the H structure functions is found to be negligible, we ignore the interference of these 2 sets of amplitudes. One can then subtract the theoretical expectations for the fusion processes from the $e^-e^+ \rightarrow H + X$ experimental cross sections, and then analyze the data according to (12, 13, ..., 19) leading to Figs.1,2,3.

5 New contributions

We now turn to possible new physics contributions. These are chosen to obey (1), so that the description in terms of the $V_i$ in (13,19) remains possible. We treat the following examples:

• **Possible new scalar particles** $s$. We compute the amplitudes of the process $e^+e^- \rightarrow V \rightarrow ss$, followed by $s \rightarrow H + s$ (2 diagrams). If $s$ is neutral, then the only gauge boson it can couple to is $Z$. If $s$ is charged, then it can also couple to the photon. Suitable values for the $ssH$-couplings are chosen, so that the overall magnitudes of the new physics effects are comparable to the SM one. The discrimination of new physics effects is then mainly based on studying the shapes of the cross section and the structure functions.

We consider three possible $ss$-pairs, using different $s$-masses:

s1: $s=$neutral, $m_s=0.1$ TeV,

s2: $s=$neutral, $m_s=0.28$ TeV,

s3: $s=$charged, $m_s=0.28$ TeV.

In all cases, we find that heavy masses give quickly a strong decrease at high $p_H$.

• **New fermion particles** $b'$. The involved new physics is described by two diagrams through the processes $e^-e^+ \rightarrow V \rightarrow b'b'$, where $V = \gamma, Z$, followed by $b' \rightarrow H + b'$ or $\bar{b'} \rightarrow H + \bar{b'}$, where $b'$ is a new heavy b fermion. For the illustrations we choose $m_{b'}=0.25$ TeV. This way, one may study how the distributions among the various $V_i$ reflect the fermionic nature.

• **A scalar parton model.** Another type of a schematic example could be obtained by imitating the parton model of hadronic Deep Inelastic Scattering. Starting e.g. by assuming that transitions like $\gamma, Z \rightarrow x + x'$ exist, where $x$ and $x'$ are particles...
that may fragment to $H$, through transitions like $x \to H + \text{“anything”}$ and $x' \to H + \text{“anything”}$. The parton model fragmentation functions $D_x^H(z)$ and $D_{x'}^H(z)$, are modelized for example through typical $z^a(1-z)^b$ forms, with $z = 2p_H^0/\sqrt{s}$. The corresponding $W_i^{\alpha\beta}$ structure functions are then obtained by multiplying the basic $e^-e^+\to \gamma, Z \to x + x'$ cross section by the above fragmentation functions.

Examples could be given by taking $x, x'$ as scalars, fermions or gauge bosons, and correspondingly choosing their fragmentation functions and the corresponding $W_i^{\alpha\beta}$ ones. Here we use a simple example with a neutral scalar $x = x'$ coupled to $Z$ only. Neglecting masses for simplicity, we obtain a non-vanishing contribution only for the $W_{2}^{ZZ}$, given by

$$W_{2}^{ZZ} = g_{Zeff}^2 \frac{8m_H^2}{s \bar{s}^3} D(z), \quad \text{with} \quad D(z) = 12z(1-z). \quad (22)$$

In such a case, non-vanishing “parton” contributions are only generated for $V_2, 5, 7$. The choice $g_{Zeff}^2 \simeq 0.04$ is made in (22), so that this contribution has a magnitude comparable to the other new physics effects discussed above.

We next turn to the illustration of the above new physics effects and compare them to the related SM contributions. These are presented in Figs.5, ...8. As already stated, with the choice of the new physics couplings we have made for the various models, the differences among the various new physics models we discuss, are concentrated in the shapes of the various distributions.

In Figs.5 first, we present the contributions of the scalar $s_1, s_2, s_3$, the fermion $b'$ and the parton model discussed above, to the unpolarized differential cross sections. In addition, we also show in the upper and lower panels, the sSM (only the s-channel contributions) and SMtot (both s-channel and t,u channel contributions) standard model cases respectively. One can immediately see the differences in the shape and magnitude of the new contributions ($s_1, s_2, s_3, b'$, parton) with respect to those of the SM contribution, especially for high energy and $p_H$.

The origins of these differences can be analyzed by looking at the various $V_i$ combinations in Figs.6 ...8. The effects are much more spectacular than in the unpolarized cross section. Each new contribution gives a specific modification of the $V_{1,...7}$.

The spin is one reason for these differences; at high energy and $p_H$, the scalars (including the scalar parton model) do not contribute to $V_{1,3,6}$. The masses are another reason, as one can see by comparing the shapes of $s_1$ and $s_2, s_3$. This feature could be useful for identifying invisible matter.

In more detail, Figs.8 present the angular independent structure functions $V_1, V_4$ as functions of $p_H$. These are usually the largest and they are positive for all $p_H$. In contrast to them, the structure functions $V_2, V_3, V_5$ (Figs.7) and $V_6, V_7$ (Figs.8) may change sign as $p_H$ varies, and are usually considerably smaller. Exceptions appear for the parton contributions at $\sqrt{s} = 5\text{TeV}$ and low $p_H$, for $V_2, V_5, V_7$; and also for the $s_3$-contribution to $V_5$ at $p_H \sim 0.5\text{TeV}$.

---

2As usual, the normalization $\int_0^1 zD(z)dz = 1$ is used.
6 Conclusions and possible future developments

In this paper we propose an analysis of the Higgs boson structure functions in $e^-e^+$ collisions.

In doing so, we have first computed the theoretical expectations for the SM contributions to these structure functions and to their combinations appearing in the angular terms of the inclusive cross section $e^-e^+ \rightarrow H + \text{"anything"}$. We have then given examples of possible new particle contributions and examined how they modify the shapes of the distributions of the various Higgs boson structure functions, such that one can suspect what type of new particles are produced, without observing them.

These differences arise from the spins, masses and couplings of the new particles involved, and reflect in the $p_H$ dependencies and the signs and magnitudes of the various $W_i$ or of their effective combinations $V_i$. They are rather spectacular, first in the global unpolarized differential cross sections and more drastically in the various $V_i$ combinations controlling its angular components (see illustrations). The shapes of these distributions may allow to guess what type of new particle (spin, mass) is responsible of a departure from SM when it is observed, even if this particle is not visible.

Our conclusion is then the following: The shapes of the Higgs boson structure functions can tell us something about new physics.

The output of this first work is essentially a suggestion for further more detailed phenomenological and experimental studies. Obviously several improvements could be performed; like a complete treatment including higher orders and background processes.

There should also be the possibility of studies of other inclusive processes. The closest one to the case considered in the present work being for example $q\bar{q} \rightarrow H + \text{"anything"}$, in particular $q\bar{q}' \rightarrow W \rightarrow H + \text{"anything"}$ at LHC. But other processes, for example with initial photons or gluons, $\gamma\gamma \rightarrow H + \text{"anything"}$, $gg \rightarrow H + \text{"anything"}$ could also be considered.

Figure 1: Structure functions for the s-channel SM final states $X = ZH$, $X = tt$, and the lighter quark or lepton final states $X = \bar{f}f$ called "light"; see (20). Their sum denoted as $sSM$ is also given. Left panels correspond to $\sqrt{s} = 1\text{TeV}$, and right panels to $\sqrt{s} = 5\text{TeV}$. Upper panels present the differential cross section measured in $\text{fb}/\text{TeV}$, while middle and lower panels denote respectively $V_1$ and $V_4$ measured in $\text{fb}\text{TeV}^2$. 

13
Figure 2: s-channel SM structure functions as in Fig. 1. Upper, middle and lower panels correspond respectively to $V_2$, $V_3$, $V_5$; see [14, 15, 17].
Figure 3: $s$-channel SM structure functions as in Fig. 1. Upper and lower panels correspond respectively to $V_6$, $V_7$; [18][19].
Figure 4: The SM differential cross sections \((12)\) from the sum of the the X-channels in \((20)\) called sSM, together with the contributions from the t- or u-channels in \((21)\). The total contribution from all channels \((20,21)\) describes the total SM result called SM\(_{\text{tot}}\). Left panel corresponds to \(\sqrt{s} = 1\)TeV and the right one to \(\sqrt{s} = 5\)TeV.
Figure 5: The SM unpolarized differential cross sections \((12)\) together with the new physics contributions \(s_1, s_2, s_3, b',\) and the parton-ones discussed in Section 5. The SM results in the upper panels only involve \(s_{\text{SM}},\) while those at the lower panels involve \(s_{\text{tot}};\) compare Figs.4. Again, left panels correspond to \(\sqrt{s} = 1\) TeV, and right panels to \(\sqrt{s} = 5\) TeV.
Figure 6: Structure functions $V_1$ and $V_4$ measured in fb$\sqrt{s}$, for the s-channel forms $s$SM (see Figs. 4), together with the new physics forms $s_1$, $s_2$, $s_3$, $b'$ and the parton contributions. Left panels correspond to $\sqrt{s} = 1$TeV, and right panels to $\sqrt{s} = 5$TeV.
Figure 7: As in Fig.6 for $V_2$, $V_3$, $V_5$, shown respectively in the upper, middle and lower panels.
Figure 8: As in Fig. 6 for $V_6$, $V_7$, shown respectively in the upper and lower panels.
